Wanted: Pioneers for man's last frontier

Help us build power for the conquest of space:

LARGE ROCKET ENGINES

WILLIAM J. CECKA, JR., 35, aeronautical engineer, (Univ. of Minn. '43), was called from North American by the Air Force for experimental rocket work in 1944. On his return, he progressed rapidly: 1948, supervisory test job; 1950, group engineer, operations; 1953 engineering group leader; 1955, section chief of engineering test. Using our refund plan, he has his M.Sc. in sight.

GEORGE P. SUTTON, in the 13 brilliant years since receiving his MSME, Cal Tech, has made rocketry a way of life. His reputation is world wide. His book *Rocket Propulsion Elements* is recognized as the standard text on the subject. Still active academically, but no bookworm, he takes time off occasionally to study the laws of motion at some of the world's better ski resorts.

Tomorrow's count down already fills the air at ROCKETDYNE'S 1,600-acre Field Test Laboratory in the Santa Susana Mountains near Los Angeles. For this is the free world's largest workshop for rocket engineering—the great new industry that is now attracting many of the finest scientific and engineering minds in the country.

EXACTING RESEARCH, EXCITING PROSPECTS

From the rock-bedded test stands come 2 miles of recordings per day—data far ahead of available texts. The big rocket engine is a flying chemical factory in an absolute state of automation. It tolerates no error. It demands ductwork, turbomachinery, pressure chambers, orifices, injectors, heat exchangers and closed-loop control systems that must put hundreds of pounds of precisely mixed propellants into controlled combustion every second. Tolerances go down to 0.0001″. Temperatures range from -250° F to 5000° F. Process time constants occur in "steady state conditions" of the order of a few milliseconds. Event sequences are minutely evaluated, as basis of designed performance predictions of extreme exactitude.

The methods now being developed at ROCKETDYNE for producing effective power to the limits of mechanical stress will have wide application. Such experience is practically unobtainable anywhere else. As a graduate engineer, *you* may be able to participate—now.

What motivates a rocket engineer? Well, the material advantages are high; but it is the work itself that draws him most. He feels the same incentive that moved Magellan . . . spurred the Wright Brothers . . . and beckoned again to Goddard as he flew the first liquid rocket at Auburn, Mass. in 1926.

At ROCKETDYNE, you can do this kind of pioneering in a management climate that stimulates personal growth—and rewards it to the limits of your ability. Academically, too, you can grow with our financial aid; some of the nation's finest universities are close by.

INTERESTING BOOKLET: "The Big Challenge"—facts on design criteria and development approaches used at ROCKETDYNE. Write for your personal copy, specifying your degree and years of post-college experience. Address: A. W. Jamieson, Engineering Personnel Dept. MAR, 6633 Canoga Ave., Canoga Park, California.

To engineers interested in entering the field of

INERTIAL GUIDANCE

E. V. Stearns (left), head of the Inertial Guidance Department, discusses navigation systems mechanization with Inertial Guidance Scientist R. L. McKenzie (center) and Senior Electronics Scientist D. G. Peterson.

Here is a field whose potential is equalled by the magnitude of its problems. The development of components with extraordinary precision alone offers unmatched scope for achievement.

At Lockheed's Research Center in Palo Alto, engineers and scientists are working on a number of different inertial guidance systems. They are involved in all phases of inertial guidance and navigation.

Their expanding activities have created new positions for those possessing backgrounds in:

- **Mathematics**
- **Physics**
- **Electronics (such as magnetic amplifiers)**
- **Servomechanisms**
- **Flight Controls**
- **Precision mechanical and instrumentation development**
- **Special purpose computer design**

Engineers and scientists possessing experience or keen interest in advanced applications of inertial guidance are invited to write.

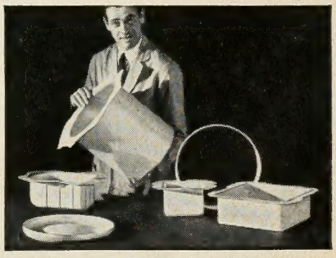
DOW

Dow high temperature magnesium alloys have excellent fabrication characteristics

Lightweight structural metals with high strength, stiffness and elasticity at elevated temperatures! A new group of Dow magnesium alloys offers a great combination of these properties without the fabricating difficulties normally experienced with other high temperature materials.

Specially developed for use in airframes, missile and engine structures, the new alloys are already making weight reductions possible for several manufacturers. These alloys show advantages at temperatures up to 700°F. Limited test data on properties up to 800°F. are available for some of them.

FABRICATION: Fabrication characteristics are equal to those of standard magnesium alloys.



WELDABILITY: 95 to 100% weld efficiency at elevated temperatures.

FORMABILITY: Single deep draws can be easily accomplished.

MACHINABILITY: Best machining characteristics of any structural metal.

One of the new alloys is magnesium-thorium composition HK31A. It is now available in rolled form from stock. Castings and sheet in mill quantities are also readily available. A companion alloy for extruded shapes and forgings will soon be in production.

For more information about the new high temperature magnesium alloys, contact your nearest Dow Sales Office or write to THE DOW CHEMICAL COMPANY, Magnesium Sales Department Midland, Michigan.

EASILY FORMED. These HK31A parts were drawn using production dies and processes for standard magnesium alloys. The parts retained a higher percentage of original properties than standard alloys.

For the Orphaned ABMA --Independence!

The most experienced ballistic missile research and development group in the world is hanging in the balance.

By an extraordinary stroke of irony, Defense Secretary Wilson's controversial memorandum on missile assignments has orphaned the Army Ballistic Missile Agency.

If by any unlikely chance there is any doubt about the value of ABMA, let the record state that this is the group headed by the talented Wernher von Braun. Let the record show that ABMA is without peer in the world among research or military organizations in its experience in ballistic missile development.

Now that Secretary Wilson has decreed that the Army should have nothing to do with long range ballistic missiles, what is to become of ABMA?

The Navy well may provide the answer. In an exclusive interview in this issue of m/r, with Assistant Secretary of the Navy for Air, Garrison Norton, a gratifying statement occurs: The Navy hopes to make the fullest possible use of ABMA. This is in spite of the fact that the Army and the Navy now are going in separate directions for development of intermediate range ballistic missiles.

We commend the Navy for its foresightedness. Although the technological requirement for a fleet ballistic missile is somewhat different than for the Army's long range ballistic missile, the fact remains that 1200-mile or 1500-mile range ballistic rockets must be based on one and the same design concept.

We think the best solution to the ABMA problem, however, would be to establish this talented group as a separate and independent *national ballistic missile research agency*, somewhat similar in scope to the highly successful National Advisory Committee for Aeronautics.

Meanwhile, the furor over the Wilson memorandum is far from over. It is gaining momentum now that Congress has convened with a number of Senators and Congressmen insisting upon a full-scale review of the Wilson action. There will be a strong demand, based both on the Army's proven record of achievement and on definitions of weapons in tomorrow's world, that the Army be permitted the right to incorporate intermediate range ballistic missiles in its weapon arsenal.

The immediate problem is to save the ABMA team whose morale is understandably at a very low point. At a time when our ballistic missile race is on in the world arena, it is tragic that ABMA is a victim (temporarily, at least) of inter-service competition and squabbles.

WAYNE W. PARRISH.

design with austenal in mi

New **microcast** *Research Facilities will in investment casting applications and give desi engineers greater latitude in planning parts.*

A new facility for advanced research is now under constru Austenal to broaden the many applications of Microcast—to m methods and alloys available, and to allow greater freedom and in part designing.

One section of this new plant will contain the equipment famili investment casting industry and in addition, equipment neces investigating numerous other methods of making and treating Adjoining the foundry area will be shops for pilot line and expe work in mold making, waxing, investing and finishing. There w area containing laboratories for mechanical testing, physical metallographic investigations, refractories development and investigations.

Contact your Austenal engineer today and ask him to show Austenal's continuing program of research and development you design greater performance and reliability into the in castings you require.

It's **NEW** *from Austenal*

"Design with Microcast in Mind," Austenal's new informative booklet, tells you how to get the greatest benefit from Microcast, showing the great latitude of design possibilities, alloys available and a great deal more, valuable information. Write for it today.

Multi-million dollar ram jet test facility at Curtiss-Wright Wood-Ridge

CURTISS-WRIGHT

RAM JETS

spearhead America's first-line defense

One of the world's most advanced jet engines, the Curtiss-Wright Ram Jet develops its greatest efficiency at speeds above 1800 miles per hour, and at very high altitudes. Since the announcement, in 1952, of Curtiss-Wright's development of the world's first supersonic ram jet to be successfully flown, the Company has intensified its work on longer range ram jets for piloted aircraft and guided missiles – powerplants that are of first rank importance in America's National Defense programs. Curtiss-Wright's giant ram jet test facility at Wood-Ridge sets the pace for America's ram jet progress.

In ram jets, rockets, turbojets, turboprops, Turbo Compounds and conventional piston engines – in power for *every* purpose – Curtiss-Wright maintains a continuing program of advanced research and development.

THE BIG PICTURE IN ELECTRONICS

A rocket to the moon within 10 years—to Mars in 25! This is the prediction of experts in the new field of astronautics.

Right or wrong, *we* can tell you this: Within months, the first man-made earth satellite will be Martin-launched, and we're already "running some numbers" on the first moon vehicle.

The direction is up—and out—and Martin is pioneering the way. To the electronics engineer with vision, this means Ceiling Infinity.

There are some challenging opportunities available. Contact J. M. Hollyday, Dept. MR-1, The Glenn L. Martin Company, Baltimore 3, Maryland.

letters

Satellite Orbit Still Questioned

To the editor:

. . . Thank you for publishing my letter, SATELLITE VS. EARTH ROTATION, p. 18, December 1956 issue MISSILE & ROCKETS, with the NRL comment. Rather than debate the question on theoretical grounds, permit me to offer familiar empirical proof.

If two boys position themselves 100 feet apart on the parade ground at Patrick AFB (Cape Carnaveral, Florida) on a north-south line, and one throws a ball into the air toward the other, the ball will be (neglecting atmospheric friction) in a free orbit just as will the satellite (although a very elliptical one which intersects the surface of the earth). If the earth "turns beneath it" while in orbit, the ball would promptly disappear to the west at some 900 miles per hour upon leaving the boy's hand; if thrown so as to remain in the air for four seconds, it would fall to the ground one mile away! Obviously the ball—and the satellite—will retain the eastward motion which it had while resting on the surface, and into whatever orbit it is dispatched, will return to the same point on the surface of the earth from which it was launched, whatever motion this point has in space. In doing so, the plane of the orbits must rotate with the rotating earth.

This argument appears to have been anticipated in only one public exposition of Vanguard motion: on page 495, April 1956 issue of NATIONAL GEOGRAPHIC MAGAZINE the following statement is made: "Any object in the grip of the air follows earth's rotation—approximately 1,000 miles per hour at the Equator. But a man-made satellite beyond the atmosphere, like the moon itself, will remain independent of earth's spin." If this idea that a satellite at 300 miles altitude will behave differently than a "satellite" baseball at 50 feet because the latter is "in the grip of the atmosphere" is taken seriously by anyone, let him disprove it by recreating the baseball experiment in miniature without the presence of an atmosphere, i.e., with a lead pellet in an evacuated bell jar. I assure him that the pellet will not crash through the west side of the jar with the speed of a rifle bullet!

Various secondary corrections have been prepared for the calculations as published in the latter part of my December letter; a limited number of copies are available upon request . . .

Charles C. Littell, Jr.
Engineering Associates
434 Patterson Rd.
Dayton 9, Ohio

Battery Output Discussion

To the editor:

. . . I have recently had an opportunity to look through your December 1956 issue of MISSILES & ROCKETS.

Three citations taken from this issue illustrate the difficulty of getting correct information these days. I refer to the figures given for energy outputs for dry cells in connection with missile operations. On page 82 Dr. S. Fred Singer includes tabular material which shows dry cells as giving out 14 watt hours per pound. Turning now to page 103, Mr. Henry P. Steier gives a figure of 50 watt hours per pound for dry cells. Finally, in his article on a case for reliable missile batteries, Joseph S. Murphy cites figures on page 112 which give four watt hours per pound for common dry cells. Obviously, there must be additional factors in all these cases which are not reflected in the text material.

While I do not expect that you have answers to this question immediately, it might be worth a small amount of research to clarify the matter . . .

J. W. Joyce
6641 32nd Street, N. W.
Washington 15, D. C.

P. R. Mallory & Co., large producer of batteries, points out rate of discharge should be part of statements on battery power per unit of weight. The company says 40-50 watt-hours/lb at 20 hour rate is correct for mercuric oxide batteries. For zinc-carbon batteries figure could run down to 4 watt-hours/lb at high discharge rate. Editor Steier was referring to mercury cells. Editor Murphy gave figures related to "missile discharge rates." ed.

More Talk About m/r

To the editor:

. . . Your office must be perpetually flooded with complimentary letters these days, if only a small fraction of your readers write to tell you that they think, as I do, that your publication is most literally tops. Again, my heartiest congratulations. The December issue of MISSILES & ROCKETS arrived this morning and I have heard more talk about it among our scientists, engineers and technicians than about any of the many other magazines our people read . . .

Bliss K. Thorne
Public Relations Director
Avco Research and Advanced Development Division
20 South Union Street
Lawrence, Massachusetts

Another Contractor For Mighty Mouse

To the editor:

. . . We were very much interested to read the article "U.S. Aircraft Rockets—How Good?" on pages 13-14-15 of your November issue, regarding the 2.75 Mighty Mouse Rocket.

However, on page 14, we were somewhat disturbed to read the information "the only three principal contractors slated to remain in the program according to the Navy are Aerojet-General Corp., Azusa, California; Hunter Douglas Aluminum Co., Riverside, California; Heintz Manufacturing Co., Philadelphia."

The Colson Corporation received the *only* contract which was awarded in November 1955 for "the rocket motor and ingenious folding fin assembly." This was for production in early 1956 which was not completed until early fall. Aerojet General Corporation received a contract, I believe in August 1956, for production in 1957.

A contract has just been awarded to the Colson Corporation for production of rocket motor assembly for 1957 . . .

J. M. Spooner

Terriers are launched from the Navy's guided-missile ship, U.S.S. *Boston*. In flight, Terrier homes unerringly on target. Missile is providing Navy with up-to-date air defense against attack.

AIR FLASK FOR A TERRIER

For the "Terrier" – the Navy's surface-to-air guided missile – ALCO produces the critical air flask which supplies pressure to guide the missile's flight-control surfaces. With this aid, the Terrier tracks and kills no matter what evasive action is taken. ALCO also builds Jato shells for the Army's "Honest John," and rocket boosters for the Air Force "Snark."

ALCO's success in missile components is drawn in large part from its broad experience in defense production – over $700 million in the past five years alone. Metal-fabricating skill from over 100 years' experience, and thermal and mechanical know-how that have made ALCO a leader in power products, also play key roles in the company's missile production.

ALCO can help in your missile program with this broad experience and with its extensive manufacturing facilities. We'd like to send you a copy of our brochure, "What Does it Take to Make a Missile?" which outlines ALCO's qualifications fully. Write Defense Products, Dept. ONM-1, P.O. Box 1065, Schenectady 1, N. Y.

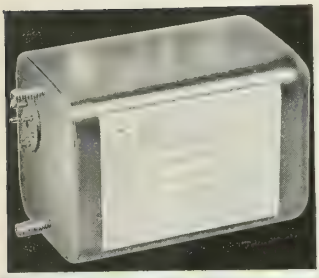
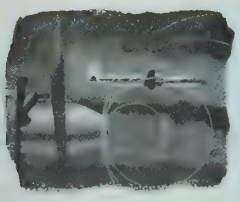
you get proved reliability in

MRC magnetic components

A complete line of compact, high-performance, components and systems for aircraft and missiles.



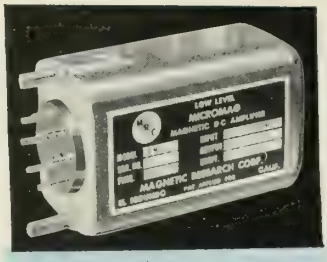


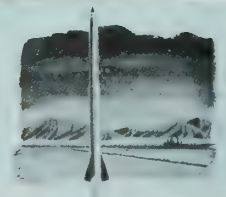
AIRBORNE INSTRUMENT POWER SOURCE MRP-5-1S

used in connection with North America's "Navajo" missile program

Exclusive flux oscillator circuitry provides smooth, transient-free 5VDC output. Regulates to 0.1% accuracy. Current capacity, 1 amp. Hermetically sealed, cast in thermosetting plastic. Short circuit-proof. Meets MIL-T-27 and MIL-E-5272-A specs. Operates on 115V-400 cycle aircraft supply mains.

MRC components and systems are daily playing vital roles in automation, computer, electronic, instrumentation, aviation and guided missile applications, where critical specs, reliability, long life and compactness are especially important.





AIRBORNE PULSE GENERATOR MP 414

used in RCA AVQ-10 Weather Mapping Radar

Use only 1 watt of power to provide 250V pulses into 500 ohms at a rate of 400 pps. Pulse width, 4.5 microseconds. Hermetically sealed. Operates on 115V-400 cycle aircraft supply. Weighs only 14 oz. Excellent also in digital computer applications. Units available from .1 to 10 megawatts and from .2 to 5 microseconds pulse width.

LOW-LEVEL D.C. SIGNAL AMPLIFIER

used in Redstone Missiles

A drift-free amplifier for aircraft and missile telemetering use. Provides 5VDC ripple-free output from 1 millivolt thermocouple or strain gauge D.C. input signals. Gain change is less than 2% for 100°C temperature change, and less than ½% for line changes from 105V to 125V. Response time, 40 milliseconds. Requires no shielding. Approx. weight 7 oz.

MAGNETIC SERVO AMPLIFIER SERIES

MA-40-400 model used in every Douglas F4D, A3D & RB-66

A complete series is available from stock, beginning at 3 watts with 0-30 cps frequency response, to the large 40-watt model with a response of 0-10 cps. These units have sinusoidal phase reversing output with transistor or tube control.

"SPECIALS"—MRC is staffed to develop fast solutions to unique problems requiring precise, specially engineered magnetic components or systems. For further technical information on MRC products and services, request bulletin GB 101

Circle No. 6 on Subscriber Service Card

From MOOG . . . **Advanced Electro-Hydraulic Servo Components**

Moog is the industry's leading producer of electro-hydraulic servo valves. This leadership has been achieved by advanced valve design resulting in high performance, high quality, reliability and efficient manufacture. The same creative approach applied to industry's newer problems has resulted in the introduction of Moog Dual Input and Servo Actuator units.

These recent achievements in the creation of advanced custom designed electro-hydraulic servo components are evidence of Moog's continuing progress.

SERVO VALVE

• These proportional "dry motor" electro-hydraulic servo valves feature high dynamic response, sensitivity, linearity and reliability. Light-weight and compact, they are also available in custom designed versions for special or advanced applications.

DUAL INPUT SERVO VALVE

• This new component provides for positioning of aircraft control surfaces by summing mechanical and electrical inputs without external use of mechanical linkages. Use of an entirely new concept offers improved performance, system simplification and saving of space and weight.

SERVO ACTUATOR UNIT

• Custom designed integrated assemblies include actuating cylinder, electro-hydraulic servo valve and feedback sensing device. In a closed loop, actuator displacement is a function of input signal.

TO THE ENGINEER IN A "HURRY"

Axiomatically, to get somewhere in a hurry, you get aboard something that moves pretty fast.

If your "somewhere" is a career in engineering, consider Moog. From three founders to five hundred employees within five years, we are today the industry's leading manufacturer of advanced electro-hydraulic servo components. Our engineers made this possible by continuous pioneering of the new and successful developments in the field. As our rapid expansion continues, we have many openings at all levels for qualified personnel.

Best time to get aboard is now.

Break-up in Army-Navy *Jupiter* Program

Polaris Fleet Ballistic Missile Project Started; Nuclear Missile Submarines Part of Program

By Erik Bergaust

The world's newest and most sophisticated underwater vessels are being planned by top Navy officials in the Pentagon. Needless to say, these submarines are nuclear-powered guided missile carriers. And they will be built to launch the solid-propellant, high-punch, intermediate-range *Polaris* Fleet Ballistic Missile.

The submarines—possibly two prototypes on order at first—are part of the *Polaris* project, which has just been confirmed to m/r by Assistant Secretary of the Navy for Air, Garrison Norton (see page 43).

Possibly the biggest missile and most complex weapons system the Navy has ever attempted, the *Polaris* will be a high-energy solid-propellant stubby 40-50-foot missile approximately 100 inches in diameter. Range is believed to be better than 800 miles. The atomic warhead in the *Polaris* will be quite sizeable, 1,000 pounds might be a fair guess. Most interesting fact about the *Polaris*, however, is that it will be a jelly- or solid-propellant rocket designed to be launched from submerged submarines as well as from surface vessels or surface installations.

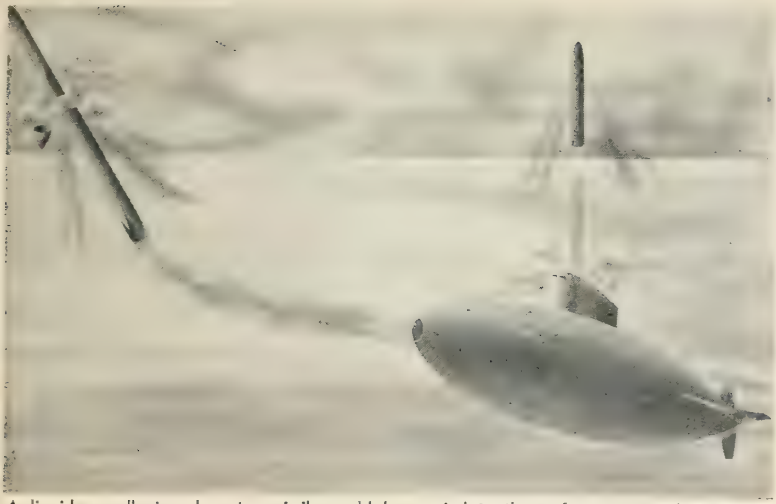
Both liquid and solid-propellant rockets can be fired from underwater. But handling of liquid propellants at sea (or land, for that matter) involves several hazards that the Navy doesn't care for too much. And in view of recent progress in the field of high-energy solid propellants the Navy has pulled away from the joint Army/Navy *Jupiter* program and set out to develop its own intermediate-range guided rocket.

The Army's remarkable ballistic rocket team under the direction of Dr. Wernher von Braun is understood to have helped the Navy create this fabulous weapon. As a matter of fact, members of this team built underwater solid rockets 13 years ago. They mounted a launching rack holding six solid-propellant rockets on the deck of a submarine. From as deep as 100 feet the stubby *Borsig* rockets zoomed to the surface at an angle of 45 degrees and then streaked aloft into the blue skies over Peenemunde. The German Admiralty turned the weapons system down—because it was developed for them by a competing service—the Army.

Nevertheless, the technical reports on underwater-launched missiles have been available in this country ever since Dr. Wernher von Braun and his missile team came to the United States. Not until recently, however, did our own Navy realize the potentials that this principle offers.

Liquid-propellant sub missiles also have been studied in recent years. Such missiles must be placed inside a container or watertight shell.

Once the vehicle pops out of the water, the outer shell or container will throw away the nose cone, and the actual missile will roar aloft without having been in touch with water, and leaving the container behind. Because of the buoyancy the missile might ascend in a straight line to the surface and take off vertically.



Fueling of a liquid propellant submarine missile must take place at dockside before the sub sets out on its mission, and the art of keeping liquid fuel vaporization at a minimum—and keeping liquid oxygen at the required minus 297 degrees Fahrenheit—is tricky, indeed. Secondly, the underwater missile container adds to the complexity of the system.

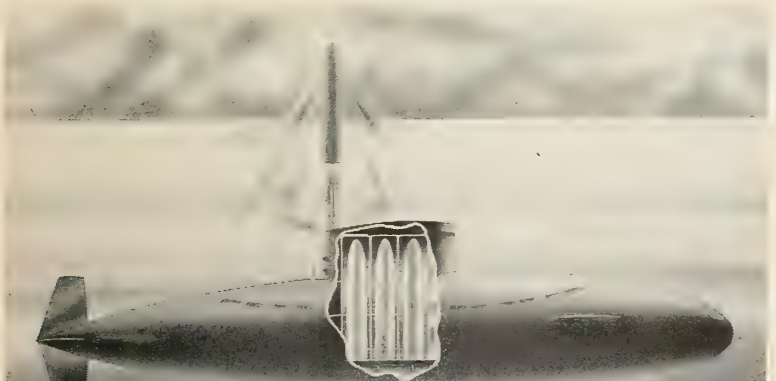
While our liquid-propellant rockets are more efficient than solid units—pound for pound, and sizewise, the solid-propellant underwater rocket has many advantages.

The solid rocket doesn't require the outer shell or container. It doesn't require the propellant insulation gear, nor any additional booster or torpedo-type powerplant. Pressurization requirement is insignificant.

Russia Has Polaris-type Rockets

Russia is understood to have developed solid-propellant 650-mile rockets already. These missiles can be launched from submarines; they can also be fired from land installations. Reports say these rockets already make up part of the Russian military set-up in Europe. Alfred J. Zaehringer, m/r Propulsion Editor, and recognized solid-propellant expert, says the Russians have advanced rapidly in the field of Powder rockets, as a matter of fact, Zaehringer says, Russia has put more emphasis on solid rather than on liquid propellants. This means Russian ballistic rockets are larger in size—and possibly clumsy to handle—but their fire power and efficiency must not be underestimated. A round-up on Russian rocketry, including their efforts in the field of solids, will be presented in the February issue of m/r.

A liquid-propellant underwater missile could be carried to the surface in torpedo-type container. Both solid and liquid rockets could be launched this way, but . . .



Furthermore, because of the water resistance, a missile moves rather slowly under water. It burns only a small amount of propellants before popping out of the sea; the water back pressure on the combustion holds the burning back.

So the Navy picked the solid-propellant version. And, of course, this missile may be launched from surface vessels as well; from cruisers, battleships and carriers, and from any beach head. The range, however, will probably be considerably less than if liquid propellants were employed.

Missiles Systems Division of Lockheed Aircraft Corporation is to build the *Polaris*. Aerojet-General Corporation will be responsible for the propulsion system, and General Electric and Massachusetts Institute of Technology will be in charge of guidance and fire control.

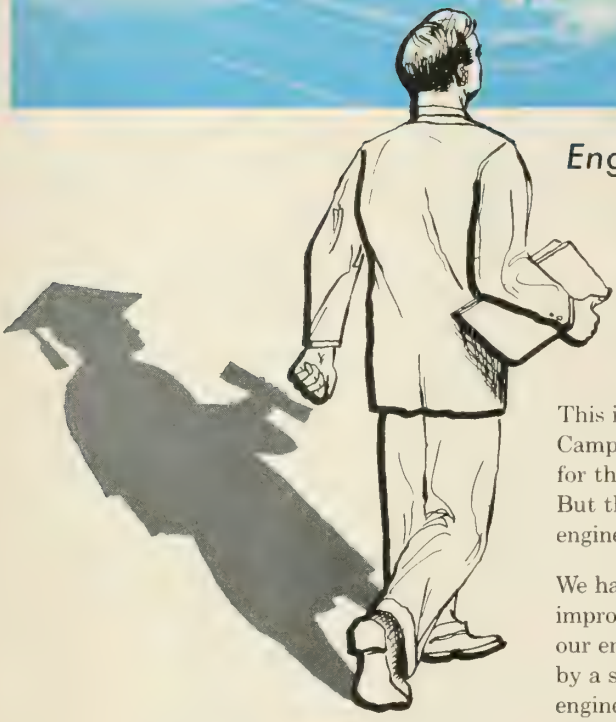
The submarines must necessarily be large, and since the advantage of this weapons system lies in the fact that the ships may hide off an enemy's coast for months, they are to be fitted with nuclear powerplants. The first atomic powered *Polaris* sub probably will slide down the ways in 1961-2. A whole fleet of them could be available by 1965. It is understood that the *Polaris* subs will employ the *Albacore* fast hull, giving the vessels a speed of about 50 knots underwater.

Unofficial reports from Russia have hinted that the Soviets have developed their submarine missiles to the point where the 600-unit Red submarine fleet now is in position to launch deadly underwater missiles over distances of 650 miles or more from submerged positions and close to 1,500 miles from surface positions.

. . . storage problem probably will determine launching technique to be employed. Polaris sub-carrier supposedly will be blimp-shaped like the U.S.S. Albacore.

Scientists Discuss Mars Observation

Extensive astronomical observations of Mars during its close approach late last summer and early fall formed the basis for a recent symposium held jointly by the American Astronomical Society and the American Association for the Advancement of Science in New York City. Conferees pointed out much work still had to be done before a full assessment of the close approach of Mars could be made. The international Mars committee, with headquarters at Lowell Observatory, Flagstaff, Arizona, coordinated the various phases of the close approach. Participants promised that reports on the occasion would be forthcoming.



Chairman of the symposium was Fred L. Whipple, Director of the Harvard Observatory. Participants included G. P. Kuiper of McDonald Observatory, Seth B. Nickolson (speaking for R. S. Richardson) of Palomar-Mt. Wilson Observatories, S. L. Hess of Florida State University and Lowell Observatory, C. C. Kiess of the U.S. Bureau of Standards, and C. H. Meyer of the Naval Research Laboratory. In addition to the papers presented at the symposium, two other Mars reports were given during the four-day AAS session, one by W. N. Sinton of Harvard Observatory on "A Spectroscopic Search for Vegetation on Mars," and one by S. L. Hess entitled "Blue Haze and the Vertical Structure of the Martian Atmosphere."

The color of Mars drew some attention during the symposium. Polarcaps are probably almost pure white, with perhaps a faint tinge of ivory. Investigation of the color of the desert areas have been made. Dark ochre to red yellow are characteristically reported when the planet is submerged into red light, but large contrasts are common. Possible tie-ins between the characteristics of the atmosphere and surface colorings were mentioned. Dr. Kuiper, for example, suggested that the "canals" may be streaks, caused by varying albedos.

The possibility that the dark areas are essentially lava fields, perhaps partially covered with some sort of vegetation, was introduced.

Periodic color changes might be caused by dust settling on these fields, only to be subsequently blown away. Dr. Kuiper's studies also covered the oblateness of Mars, tidal friction effects on Phobos (one of its moons) and infrared investigations.

Engineers Seeking —

continued professional development . . .

This is McDonnell's partially completed "Engineering Campus", where engineers will find an ideal atmosphere for their continued professional development. But these ultra-modern, completely equipped engineering facilities are only part of the picture.

We have a well planned, organized program for improving the professional status of each member of our engineering staff. This program includes counseling by a special staff of Career Analysts, and advanced engineering training in our complete in-plant training program or at one of our two local universities.

How about your own "professional development"? Engineers of all types are invited to investigate employment opportunities at MAC by writing:

MACareers Are Successful Careers

McDONNELL *Aircraft Corporation*

US Air Force To Begin ICBM Training

Air Force will introduce long-range ballistic missile capability into the strategic Air Command late in fiscal 1958, according to present plans. While the plans do not encompass actual operational wings, they do provide for acquisition of sufficient hardware on which to start an intensive training program. First construction on ICBM batteries may also take place.

Under the present timetable, ICBM missile wings will be integrated into SAC within the next five years. Fiscal 1958 training on hardware will be carried out at Western Development Command's newly acquired Camp Cooke, Calif., site, as well as at SAC itself. Personnel will be indoctrinated on components, assembly, parts identification, fueling, etc.

The missile wings will be similar in composition to the heavy SAC bomber wings. First missile wings will not, it has been strongly asserted, replace the bombers. They will initially be used as an adjunct in a program to determine where missiles properly fit in the SAC mission picture. It is now estimated that missile wings probably will have to be manned by more than the 3,000 personnel now attached to heavy bomber wings.

Missile battery sites will be located according to a dispersal plan but in proximity to SAC bases, which will provide necessary support.

The plan ties in closely with upcoming considerations on the Defense Budget. In budget research and development requests both President Eisenhower and Defense Secretary Wilson have put an untouchable priority on ICBM *Titan* and *Atlas* projects. Other projects have been robbed to fulfill the order, including *Navaho*.

Reliable sources have revealed that the ICBM is now close to the same time schedule as the older *Navaho* project. *Navaho*, however, which boasts a more accurate guidance system, will be kept in tact. AF is not overlooking the possibility that bugs may develop in ICBM testing and that *Navaho* will then become more attractive.

But as the budget now stands, pessimism prevails as to *Navaho's* production future. AF will go down fighting, however, to preserve its status and retain it as a research missile if it cannot get a big enough budget to support both.

Maximum effort will be directed in the coming months to pulling the ICBM programs forward to the point of production for training. One top official noted: "We won't see missiles standing on gantries in fiscal 1958, but we will need some for training to establish count-down procedures and so forth."

The admittedly optimistic timeschedule is felt to be mandatory to get the missile capability out of the talking stage.

The Convair *Atlas* was recently described by the British magazine *Flight* as a vehicle standing about 100 feet in height and weighing about 90,000 ibs., presumably empty. The periodical described the *Atlas* as a single-stage missile employing a liquid-propellant sustainer motor of 135,000 lbs. thrust plus two booster motors of 100,000 lbs. thrust each mounted in jettisonable nacelles at the base of the rocket. It is further understood that the *Atlas* prototype is now being assembled at Patrick AFB, Fla., for firing sometime this year.

While the *Navaho* can carry a heavier warhead than its ballistic competitors, this feature is no longer of much significance in view of the appalling energy yield of modern thermonuclear explosives. But it does have the advantage of greater accuracy in guidance since it theoretically can be controlled all the way to target. For this reason, the AF believes it has a place in the combat inventory alongside ICBM—provided sufficient funds are available, but economy will dictate the final solution.

In the Age of Missiles and Rockets

It may be Delphic that a national toy catalogue lists bows and arrows immediately after atomic submarines, electronic ray guns and Inter-Continental Missiles. But be that as it may, in the toyland world of children, the age of tomorrow is here today.

Almost every electronic, supersonic and remote controlled vehicle the adult world strives to perfect was already operational under the Christmas tree the night St. Nicholas was last abroad. And all had a singular advantage over their grown-up counterparts: They are not lethal.

Sales of radar rocket cannon, air pressure propelled rockets, space ships, guided missile bases and the like have grown to a $10 million business, up 100% in the last year, according to the Toy Manufacturers of the U.S.A., Inc. And there's no sign that the trend is about to reverse itself anytime in the near future . . .

One day these children who now play at space flight may well participate in the real thing, the beginning of the exploration of outer space.

Wilson's Missile Program Far From Settled

By Seabrook Hull

As m/r went to press, no decision had yet been reached on how to follow up Defense Secretary C. E. Wilson's November Memorandum on roles and missions. This was particularly true where missiles were concerned. Very much up in the air, for example, was the future—if any—of the Army Ballistic Missile Agency.

But some things were clear:

—— Air Force's first-choice solution was to take over ABMA lock, stock and barrel and transfer it bodily to the AF. Barring that, AF may want the heart of ABMA—the Wernher von Braun team—broken up, with its experts filtering off into industry, preferably to firms with AF ballistics missile contracts.

—— As for the Army, parts of it anyhow seemed ready for a fight: At stake was one of the world's most proved ballistic missile research and development groups and a 1650-mile Intermediate Range Ballistic Missile, *Jupiter*, which Army figured it had every tactical and strategic reason for using at will in combat.

—— The Navy, in its quiet, sophisticated way, had won the biggest victory of all. The sea-going service was no longer a junior partner in somebody else's IRBM program, but instead had Wilson's official go ahead to develop its own Fleet Ballistic Missile, *Polaris*. Moreover, once it was working, the Navy had assurance it would be able to use it operationally.

—— Interservice politics seemed to be playing a bigger role in the Army-Air Force squabble than basic considerations of national security. For that reason Congress—determined to find out what all the fuss is about—would probably have the biggest say in the final outcome.

The basic ruckus seems to date clearly from the 1947 Key West roles and missions directive that gave the newly-formed U.S. Air Force sole responsibility for the strategic delivery of nuclear weapons. It was then that AF and Navy slugged it out in the headlines, the latter determined to discredit the B-36 superbomber and the former bent on sinking the supercarriers.

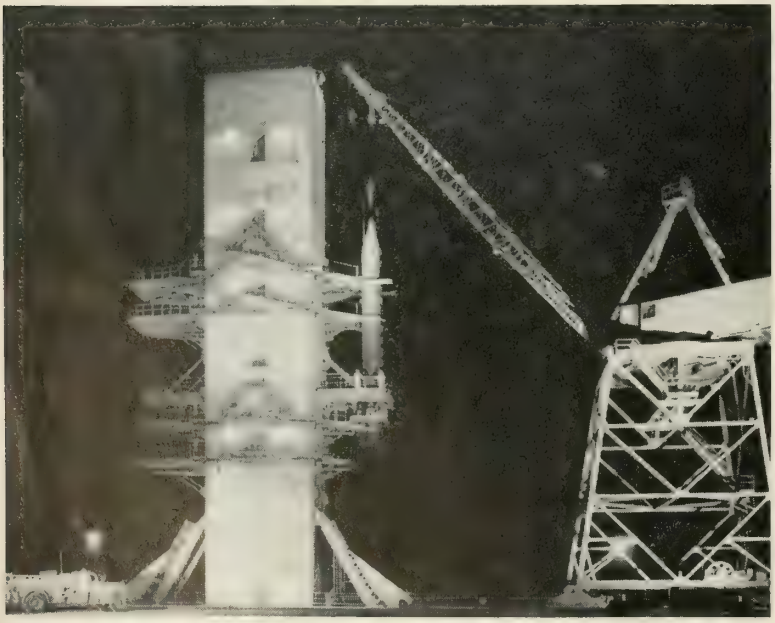
After a lot of noise and foolish talk, this squabble was "compromised" by allowing both services to keep their "sitting ducks." It is interesting to note, however, that then, as now, it was the AF that hit first.

This is all history, and defining the generalities of the course and conclusion of events a decade back is a relatively simple matter.

However, sorting out a Pentagon fight that's only beginning and on which Wilson has clamped the tightest censorship is not so easy. Honest convictions abound. So do "facts". But rationalizing these "facts" and convictions into truth and good judgement is something else again. Top Army echelons, for example, seemed inclined to do just as the boss—Wilson—directs.

Sorting this one out to the interests of the country will take the trained politician's intuitive knowledge of, and long experience with people. That's a proper job for Congress.

Facts and Appearances

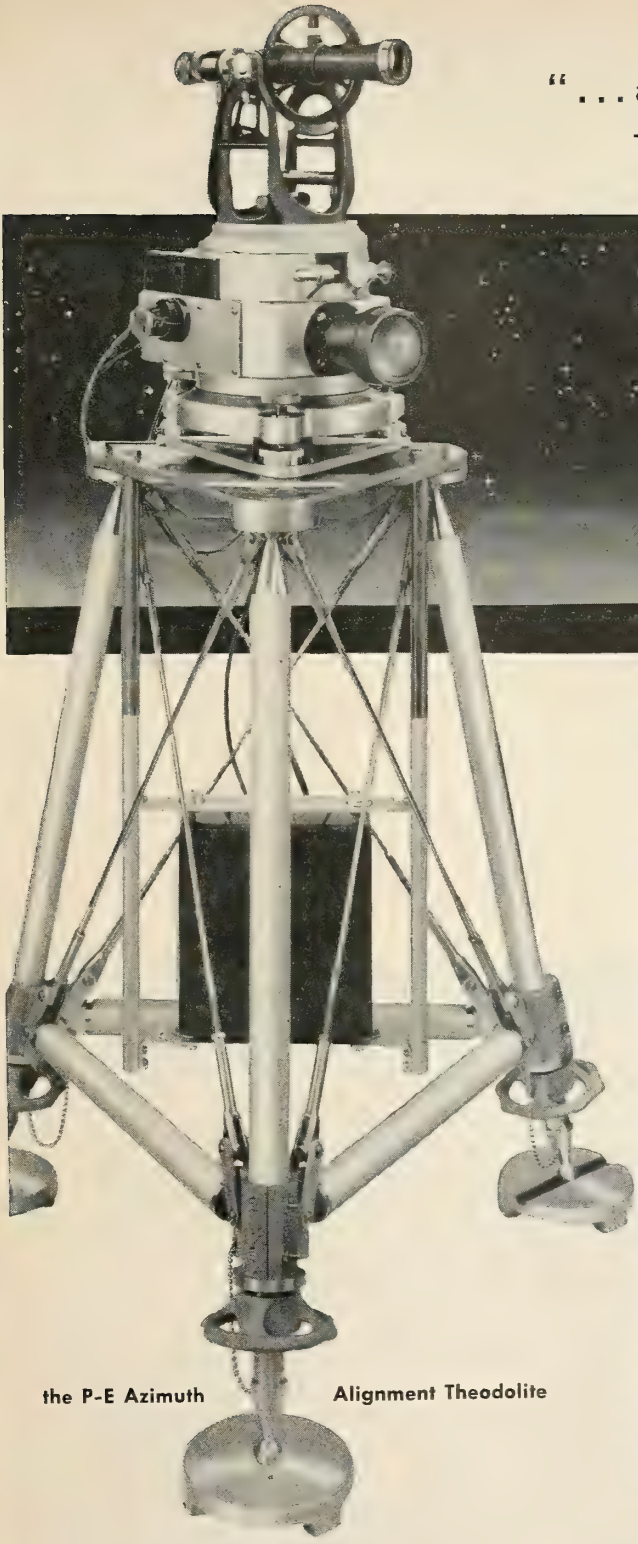


Meanwhile, the honest reporter's task is to report the few real facts that finally came to light and what various situations *appear to be*, after the best possible job of reporting. After checking top officials of Army, Navy, Air Force and Defense, these are the facts and appearances:

The first thing to make clear is that Wilson issued his now-famous November memorandum without having first decided even in general terms how the directive was to be carried out. Towards this end, repeated studies, meetings and investigations are now being undertaken. Additionally, plans had already been made to conduct an objective, "non-partisan" comparative analysis of the Army *Jupiter* and the AF *Thor*—the two IRBM principles of the current dispute.

The makings of this particular interservice fight date from the fall of 1955 when both the AF and Army were given official IRBM go-ahead. Army set up ABMA and put *Jupiter* development under Wernher von Braun. With the famous German V-2 developer were some 130 former German missile experts. In partnership with ABMA was Jet Propulsion Laboratories, of California Institute of Technology. AF contracted out *Thor* development to Douglas Aircraft Co., Bell Telephone Laboratories and the AC Sparkplug division of General Motors.

Both were announced as IRBM projects. Like the Intercontinental Ballistics Missile (ICBM), they posed unprecedented challenges to science and industry. Not the least of these was the requirement for very accurate guidance.



Considering information released

This test stand at ABMA's Redstone Arsenal, Huntsville, Ala., is capable of conducting two full-scale JUPITER test runs simultaneously. For an idea of the scale, note the man and truck at lower left. The missile in place is a REDSTONE.

"...and a star
to steer her by."

the P-E Azimuth Alignment Theodolite

New Directional Accuracy for Automatic Navigation Systems

To give exact directional alignment to an automatic navigation system, the P-E Automatic Azimuth Alignment Monitoring Theodolite takes a "fix" on a navigational star and transfers the resulting angular data to the controlling mechanism. The accuracy of this astral bench mark to a great extent determines subsequent directional accuracy. *So precise is this instrument that it makes possible automatic alignment of the system to within a few seconds of arc under day or night conditions.*

Where extremely fine angular data must be established, the P-E Azimuth Theodolite offers a level of performance never previously available. Accuracy, as indicated by a "no correction" output of the monitored equipment, is ±2 seconds of arc. Standard production models are available with working distances from 1 to 1500 feet. For further information on the Azimuth Theodolite, write to —

Career opportunities are open to creative engineers and designers. Send resumé to:

Engineers and Builders of Oil Hydraulic Equipment Since 1921

These new miniaturized hydraulic pumps were developed by Vickers for limited life applications such as missile and ram air turbine driven hydraulic systems . . . also for motorpump assemblies supplying emergency power on aircraft.

A distinctive feature is adaptability to manifolding and special mounting. This permits integration with the balance of a "packaged" hydraulic system to provide hydraulic power in the most compact and lightweight form yet devised. Some sizes are capable of delivering more than five horsepower per pound of weight.

Available in four size series, this miniaturized pump has the same basic characteristics as the standard Vickers piston type pump which has been establishing outstanding performance records on aircraft since 1940. Ask nearest Vickers Aircraft Application Engineer for further information.

7469

A large expansion program now in its early stages means large opportunities for additional engineers at Vickers. Write for information

so far on the destruction radius of nuclear warheads from ground zero, this would probably mean coming within a mile or two of a target 1500 miles away, or a guidance accuracy of well under 1%. Both must be able to carry thermo-nuclear warheads. And with it all, an over-riding sense of urgency, for there could be no doubt that Russian ballistic missiles got maximum effort.

Trouble brewed beneath the surface almost from the beginning. AF considered the IRBM a Tactical Air weapon and saw *Jupiter* in the hands of the Army as a threat to AF roles and missions. Army argued that with advances made in high-speed land mobility, the missile extension of artillery range to 1500 miles was not only logical but vital to a field commander in planning and covering day-to-day troop movements. Both services figured then, and still do, that much of their future importance in the missile age depended on developing and being able to use their own IRBM weapons.

Furthermore, except for the Navy with its special problems, AF insists that it have exclusive IRBM operational responsibility; that Army not be allowed to use anything over 200 miles. Navy, perhaps as part of its campaign to win the right to independent IRBM development, supports the AF stand.

Other facts undoubtedly contribute to the situation, such as the traditional jealousy between government and private industry in the field of development. *Jupiter* is primarily the product of a government team. *Thor* development, on the other hand, though paid for by AF, is the job primarily of private industry.

In the bitterness and rancor that's boiling up, you hear other comments too —that Wilson's General Motors background may have influenced his decision against the Army. Chrysler, who now manufactures the 300-mile *Redstone,* has long been thought to be the logical *Jupiter* contractor, whereas GM, through AC Sparkplug, has a very important *Thor* contract. A few scattered people will even tell you that the number of Germans on the *Jupiter* team prejudice the Army's position.

Meanwhile, both the Army and AF programs have made unexpected, rapid progress. Both the *Thor* and *Jupiter* missiles are scheduled to make their first test flights within the next few weeks. *Thor* appears to be at Patrick AFB already. *Jupiter's* reported to be en route. Once first prototypes have been fired, the normal procedure is to follow up with a number of test launchings. Then the real job of evaluating the two missiles really begins.

There are persistent reports around the rambling halls of the Pentagon that some top AF civilians as well as Defense Department missile czar E. V. Murphree have already conceded privately that *Jupiter* has the edge, particularly in the all-important field of inertial guidance.

Thus, not only was the AF threatened with having an unwelcome helpmate in what it considers its exclusive responsibility — TACAIR — but insult was to be added to injury by having that partner better equipped. Suggestions have been made at high levels that *Thor* should be dropped, but they do not appear to have gotten very far. There's every indication instead that, unless Congress steps in, the best of *Jupiter* will be lifted for the *Thor* and the former dropped. An Army suggestion is that, considering the importance of "getting there firstest with the mostest," development on both missiles should continue full tilt.

ICBM Duplication

An AF answer to this view is that the country cannot afford the expense in money and manpower of two duplicate IRBM projects. AF appears to feel that it waters down possible maximum effort on other high priority projects. The question may be raised: What about the AF's two ICBM projects?

Though the Navy reports excellent technical liaison with ABMA during the life of their joint venture, there's little doubt that Navy's glad to be out on its own—free of the liquid propelled *Jupiter* with all its unpleasant shipboard handling problems, and able to concentrate 100% on the solid rocket *Polaris.* Navy's also grateful, however, for having had ABMA help in getting *Polaris* off to a flying start.

The puzzling thing about Wilson's November memorandum remains that it was promulgated and released to the public without any clear idea of what to do next.

The assumption appears to have been in both the Air Force and Wilson's shop that this directive would be accepted as a matter of course; that neither private dispute nor public debate would ensue. This would seem to indicate not only a critical lack of awareness of the specific situation but of human psychology as well. For the Army reaction at the working level has not been placid acceptance. It's doubtful if tempers will be held in check during the hearings on Capitol Hill.

Most rancorous will be the restrictions reportedly imposed by Wilson on the imparting of full views and information. It is a characteristic of the Defense Secretary that he likes his department to present a composed, solid front to both the Congress and the general public. It's liable, however, to be quite a raucous show before it's over, one that may ultimately show sharp splits even within the Army itself.

Though nothing has been specifically decided, AF fully intends to get Wilson's approval and Congressional appropriations for taking over ABMA intact. If it can't do that, according to a top AF spokesman, "It will be better for the country if the ABMA team were broken up and the individuals filtered out into industry and other organizations." This view seems to ignore the fact that individual talent and ability is only one aspect of ABMA's success. The other, every bit as vital, is the ability of these men to work together.

Meanwhile, Army isn't giving up without a fight. The first battle will be to try to keep *Jupiter* development in the Army budget for at least another year. The Defense Department apparently has already decided against this. But the odds are that Congress will prevail upon Pentagon authorities to change their mind, or at least defer action until the fiscal 1959 budget is debated 12 months hence.

Army will also put up strong arguments for being given roles and missions responsibility for using IRBM's. This field, however, is one the legislators tend to shy away from, figuring that the determination of roles and missions is indeed the responsibility of the executive branch of government.

The case for retaining the ABMA-JPL team as an active ballistic missile development organization will be based on performance to date—namely a whole family of *operational* ballistic missiles with useful ranges from eight to 300 miles. They will cite *Jupiter-C* performance and the fact that Redstone Arsenal at Huntsville, Ala, has the know-how and the basic hardware for launching an earth satellite into an orbit.

An obvious question will be: Is it good business to just throw up the some $200 million that's already been spent on *Jupiter* development? In this connection Congress will be bound to ask just why the Defense Department first said "go ahead" and then a scant two years later said "stop".

On the face of it, no matter what the best decision on roles and missions might be for the country, the proof of ABMA-JPL performance is something that is neither easily discredited nor readily ignored. Leaving interservice politics, roles and missions differences and possible budget limitations out of it entirely, it may well be that Congress will see merit to the proposal m/r offers in this issue—that ABMA be established as an entirely separate agency, like NACA, free to continue its research unfettered by service rivalries. After all, the vital thing is to preserve our weapons superiority over Russia.

The first successful application of a moving pick-off head to a new, medium speed digital computer has been reported by engineers of Northrop Aircraft, Inc. With the device it is possible to record or read on 64 magnetic memory drum channels using only two pick-off heads. While the drum revolves at 1,800 rpm, the moving heads make one full up-down cycle every two seconds. Previously, 64 separated heads, one for each channel, were required, resulting in greater weight and complexity. Pick-off hid circuitry requirements, for example, have been reduced by over 95% by Northrop's new development.

$8 Million Computer to Aid Missile Test

Rapid reduction of flight test data using a powerful new computation facility is expected to permit one test missile to do the work of many during development programs.

A General Electric Co. Missile and Ordnance Systems Department engineer, A. W. Robinson, disclosed plans for the new facility in a talk before the International Congress on Rockets and Guided Missiles held in Paris, France last month.

Known as a "real time" closed-loop analysis system, two high speed "Univac" computers comprise part of the system. The computers will be installed by the USAF at Holloman AF Base in 1958. Cost will be $8 million.

The new technique is intended to allow rapid data reduction during missile flight. Reduction will take place in a few seconds and enable new instructions to be sent to the missile to obtain a wider scope of information.

Official announcement that an International Business Machines Corp. computer will calculate and predict the orbit of the *Vanguard* satellite has been made by the Navy Department.

The IBM 704 computer and 740 Cathode Ray Tube Output Recorder to be used will be located in Washington, D. C. It will first receive and process data from the *Vanguard* vehicle as the rocket reaches third-stage burnout and then will be switched to make calculations on the satellite's orbit based on data from Minitrack radio tracking stations located in the Western Hemisphere.

Dr. Paul Herget, Director of the Cincinnati Observatory will head the staff of the Washington facility to be known as the *Vanguard* Computer Center.

Construction of a building to house the Center is reportedly underway in Washington. A computer at another location will be available as a back-up facility for emergency use.

Defense Secretary Wilson's word as to who shall build and fire what missiles may not be so final as he would wish. An m/r check of Congressional sentiment on the November Memorandum on roles and missions reveals that all is not peace and acquiescence on Capitol Hill.

If the reaction at the recent American Rocket Society annual meeting (m/r, Dec., p. 24) was one of shock and consternation, that of the nation's legislators is one of astonishment and confusion, highlighted by a firm determination to "get to the bottom of things" early in session.

At stake is not only the Army's claim to a long-range artillery weapon—the Intermediate Range Ballistics Missile—but the future of what is reputed to be the hottest ballistics development team in the nation—perhaps in the world, the Army's 12,000-man Redstone Arsenal at Huntsville, Ala., including 130 former German rocket experts under Wernher von Braun.

Concentrating mainly on the members of the Senate and House Armed Services Committees—who have the biggest say in deciding who gets how much money for what—m/r found Democrats cautiously vocal; Republicans, strangely silent. One view was virtually unanimous:

"We want to know a lot more than we do now about the details leading up to this decision, and what it portends for the future."

Senator John J. Sparkman (D., Ala.), for example, has this to say:

"I think the Army is entitled to continue development of the *Jupiter*—undoubtedly, they are further along than anybody else. To stop this program now is to penalize our missile programs and already accomplished industry efficiency. It would be extremely wasteful.

"Secondly, the Army has developed the strongest possible team, and one that has shown results in course of the one year it has been operating.

"I think as a matter of military tactics the Army is entitled to the use of missiles such as the *Jupiter*, or others, wherever they can accomplish the mission for which the Army is intended.

"All services should be allowed to do all they can toward development of missiles. Let the Air Force develop their *Thor*, let the Army develop the *Jupiter*, let the Navy develop the *Polaris*. If another war should come we'll need all of them...

"It is unthinkable that the United States Government would

Capitol Hill Wants Facts on Wilson Memorandum

do such a foolhardy and wasteful thing as to throw away many millions of dollars that have already been invested in the work done by the Army. It would be little short of *criminal* to waste the tremendous brainpower and scientific knowhow the Army has been able to bring together for this program.

House Armed Services Chairman Carl Vinson would not commit himself either way, but the emphasis he gave to his no comment was significent in itself. He said:

"I shall have nothing to say until Congress reconvenes. First I want an opportunity to study the Wilson directive.

"As chairman, I don't think it behooves me to comment on the directive put out by Secretary Wilson. It is his responsibility to assign roles and missions to the armed services. This responsibility naturally includes the problems of rockets and guided missiles.

"Until the Defense Department comes before my committee to explain itself fully as to its intent, I, for one, shall withhold any comment."

And from Rep. Arthur Winstead (D., Miss.), this statement:

"I want to talk to those folks before I make up my mind. I want to talk to everybody. We have to have some executive sessions and some open sessions of our committee. I want to see us explore the whole kit and kiboodle.

"Those folks across the river will just have to come up here and explain to us what they have in mind."

Rep. Paul Kilday (D., Texas):

"I have a fear and a disappointment in this regard of the assignment of roles and missions. But it occurs to me in my fear and disappointment that we might see a new B-36 fight arising out of this new directive.

"I intend to do my best now that Congress has convened again and demand a complete review of the wasteful policy stipulated in the Wilson directive."

That there seems to be a good chance of another knock-down, drag-out fight brewing seems apparent. You hear the same kind of rumbling you did just after World War II when as a result of the 1947 Key West Roles and Missions directive, Air Force and Navy, using headlines as their big calibre ammunition tried respectively to sink the super-carrier and shoot down the B-36 "super-bomber." One member of the House Armed Services Committee put it this way:

"The Army will fight like hell to keep Dr. von Braun and its Redstone Arsenal."

The AF, it appears, is just as determined to see Redstone either eliminated or absorbed into the AF structure.

"Of course I need more time to study this question, lest I be accused of hasty ill-founded opinion. I'm a great believer in the need for strong airpower. I'm lacking in knowledge. I'm not sure the Army should be so limited. We have already limited them in the weight of their aircraft. Now limiting them in the range of their missiles and rockets makes me pause and wonder about the plans behind the Secretary's directive.

"I would like him to explain more clearly how he plans to limit distance. Personally, I feel a logical distance for these new weapons would be 500 miles.

"There are other factors I want to talk about. First of all I feel that we in the legislative branch have to allow these directives to be made by the executive branch. In this case something had to be done. It was.

"I'm in favor of doing. But that doesn't mean I'm in accord with the directive. What I'm saying is simply this: It is the role of the executive office to handle the broad overall policy as it affects the strength of our country.

"We are engaged in creating new instrumentalities for the defense of the nation. I can understand, of course, the Army must be bitterly disappointed. Undoubtedly they fear that in the complex assignments for the defense of the nation, they will have a minor role.

"I'm not prepared to discuss that aspect at this time. After all there must be the opportunity for discussion. But there is one thing I shall have my say on. Congress must stay out of the conflict, if any, on strategy and tactics. That is the role of the military men.

"In a relatively short time we shall find out the full significance of the directive. If it develops that one of our services is prejudiced, we shall, in our own way, discharge our proper duty to the people."

Rep. Victor Wickersham (D., Okla.):

"If this directive has the approval of the Joint Chiefs, that is one thing. If there is disagreement, that is something else. If there is over-lapping in the field of guided missiles, it won't hurt. Competition is good. The Russians are in this thing for keeps. So duplication will do no one any harm.

"I think Wilson is trying to do a job of coordination. But in practice, those things don't always work out as they did on paper. I can only hope that Wilson is not trying to hold down technological development.

"Another thing I'm wondering about is where the Budget Bureau fits into the directive. They have the last word over there because all they have to do is withhold funds, even funds which have been appropriated by Congress."

Maj. Gen. John B. Maderis, ABMA Commanding General, The Senator from Alabama, The Right Honorable John J. Sparkman (D.) and Maj. Gen. H. N. Toftoy, Commanding General, Redstone, Arsenal, during a visit of the Alabama Congressional delegation to the Huntsville facility last month.

Twenty-five Nations Meet in Paris For Congress on Missiles

From our correspondent

PARIS—Twenty-five nations were represented at the International Congress on Rockets and Missiles which took place in Paris last month. The meeting was organized by the Association pour l'Encouragement a la Recherche Aeronautique and its success was largely due to the work of the association's president, Jean Venturini. The 125 delegates attending the Paris meeting heard talks in several different languages on all aspects of missile and rocket activities.

G. Bory, a former French naval engineer, discussed rocket-powered missiles with special reference to development efforts between 1917 and 1947. Dr. M. Lebrun, French scientist, talked about meteorites and "flying saucers." A paper on international astronautics was read by Germany's F. L. Neher, historian of the Gesellschaft fur Weltraumforschung. He also discussed Germany's 30-year period of work on rocket development.

A. W. Robinson, of International General Electric, talked on guided missile development work in the U.S. A. Ducrocq, head of Societe Francaise d'Electronique et de Cybernetique, discussed atom-powered rockets. This subject was also discussed by Dr. F. Winterberg, a German specialist, and by two French engineers, Th. Reis and M. Gauzit.

General Electric's contribution to Vanguard was the subject of a paper by R. E. Small. Dr. G. S. James told the meeting about the Rocket Research Institute, which he heads, and also discussed the International Geophysical Year. J. Persch of U.S. Navy Ordnance, talked on the calculation of turbulent boundary-layer heat transfer in supersonic and hypersonic nozzles. Three Belgian scientists—P. Glansdorff, P. Jaumotte and S. Passelecq—discussed rocket performance. The "Litergolici" system of propulsion was described by Professor Corellli of Rome University. J. A. Vandenkerckhove of Brussels University spoke on erosive combustion of a double-base propellant. Dr. C. Belmondo, of Turin, Italy, discussed solid propellants. Propulsion problems were the subject of a paper by Captain G. Partel of Rome. Professor H. J. Zucrow and A. R. Graham of Purdue University discussed the cooling of rocket motors.

H. Bednarczyk of the Vienna Institute of Technology spoke on water vaporisation's contribution to the theory of the rocket. Professor M. J. Zucrow and J. R. Osborn of Purdue University discussed determination of the dynamic response of pressure transducers by means of the high-pressure shock tube.

In the field of ballistics and flight mechanics speakers included: J. Hely, deputy chief of France's Ecole Nationale Superieure du Genie Maritime; E. Sanger, head of Germany's Forschungsinstitut fur Physik der Strahlenantrieb; J. J. Gait of the Royal Aircraft Establishment, Farnborough; Dr. G. Fellner, of Achen, Germany; P. S. J. Vernotte of Paris; L. C. Frager of Paris; Max Plan of France's Laboratoire d'Aerothermodynamique; Dr. F. H. Devienne of France's Laboratoire Mediterraneen de Recherches Thermodynamiques; E. Finkel of France's Societe Matra; I. Rind and Jean Casteil of the French IBM company; I. Dreyfus of France's Compagnies des Machines Bull; F. H. Reynst of the Netherlands; Prof. A. Bartocci of Italy's Terni company; Dr. W. Trommsdorf of Deutsche Versuchsanstalt fur Luftfahrt; Dr. James Heyda, Allison Division, General Motors; and H. R. Voellmy of Zurich, Switzerland.

Guidance problems were discussed by the following: Colonel P. Gaudillere of France's SFT company; F. Muller of Gottingen, Germany; P. Devergne of France's Societe de Fabrication d'Instruments de Measures; Dr. W. C. Hodgson and J. N. Ryon of the Naval Research Laboratory, Washington; I. Guanella of Baden, Switzerland; and E. Perret of Zurich, Switzerland.

Ground installations and special techniques were the subject of papers by: Dr. A. Gerber of Zurich, Switzerland; General W. W. Hohener of the U.S. Navy's Bureau of Ordnance; B. Winandy, of Paris; H. Gelly of France; R. Syre of France's Pechiney company; A. Ferchaud of Paris; Dr. B. Langnecker, of Vienna; Dr. G. Golubovic of Paris; Major F. Violette of the French Air Force; and J. Duflos, head of France's Textiglass company.

Papers on the legal and economic aspects of astronautics were read by: E. Winandy; Andrew Haley of the American Rocket Society; and M. O. Maquenne of the French Societe d'Economie Politique.

A MATRA air-to-air missile has been installed underneath the prototype of the Dassault Mirage, France's Mach 1.5 fighter prototype.

Aero Digest Readers May Choose m/r

Subscribers to *Aero Digest*, which suspended publication with the December issue, will be given their choice of receiving MISSILES AND ROCKETS or AMERICAN AVIATION Magazine.

American Aviation Publications announced that it has agreed to fulfill all unexpired subscriptions to *Aero Digest*. In the event that the *Aero Digest* reader already receives the American Aviation publication of his choice, he will be given equivalent credit for extension of his subscription.

Founded in 1937 by President and publisher Wayne W. Parrish, AAP is the world's largest aviation publishing organization. In addition to the 20-year-old AMERICAN AVIATION Magazine, with a circulation of 46,000, and MISSILES AND ROCKETS, which already has attained a paid circulation of 8,500 in less than six months, the company publishes *American Aviation Daily*, *American Aviation World-Wide Directory*, the *Official Airline Guide*, the daily *Air Traffic News*, *Airports* weekly newsletter, and *Who's Who in World Aviation*. In addition, the Air Information Division provides a specialized service that digests time tables, fares and charges for scheduled airlines. Company headquarters are at 1001 Vermont Avenue, N.W., Washington, D.C.

Scott AIR-PAK

as much a part of the Weapons System as the Rocket

Fueling is one of the most important operations in the successful launching of a rocket. Since propellants are poisonous, breathing protection equipment must be worn. The Scott Air-Pak Model 8100-A2 has been designed to meet the exacting requirements of this hazardous operation. It delivers pure, fresh air, instantaneously "on demand" as required by the wearer regardless of the degree of exertion.

Special attention has been given to the metallurgy of the component parts to insure unfailing service in atmospheres of dangerous propellants such as fuming red nitric acid and unsymmetrical dimethyl-hydrazine.

The Scott Air-Pak has been established as standard equipment by Army Chemical Corps and Army Ordnance for launching crew protection.

Write for complete information.

The Scott 8100-A2 Air Pak incorporates the latest advances in chemical resisting materials. Two small compressed air cylinders are used instead of one large cylinder. This reduces bulk and makes the unit easier to wear with protective clothing.

The Scottoramic Mask which is standard equipment completely protects the eyes and face. It provides unlimited vision in all directions and helps the wearer to spot danger zones for maximum safety.

SINCE 1932 Scott FOR SAFETY—FOR SERVICE

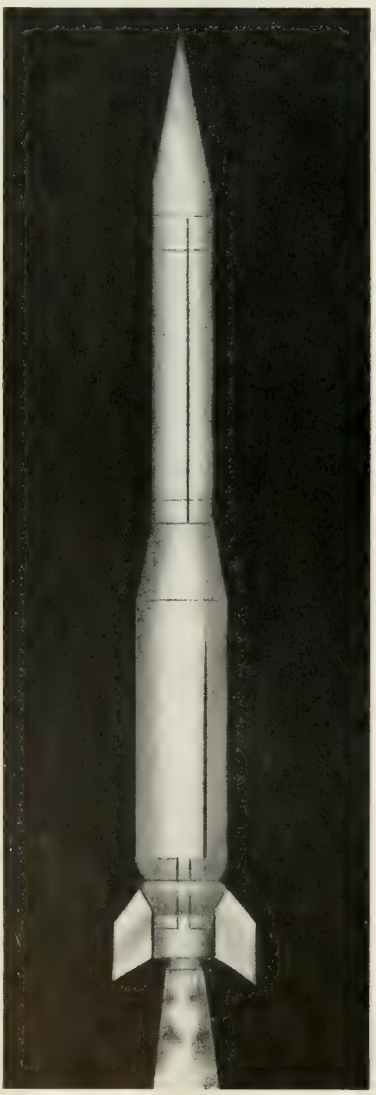
SCOTT AVIATION CORP.

Titan Configuration Revealed by Glenn L. Martin?

A Martin Company ICBM ad, in the January issue of the American Rocket Society's *Jet Propulsion* shows a more or less conventionally appearing two-stage, triple-finned rocket. A check with the Pentagon indicates that the configuration is a "bit too close" to the actual *Titan* Inter-Continental Ballistics Missile now being developed by Martin for the AF. A close replica of the missile in the ad appears below.

A Martin Co. spokesman when asked to comment on their ICBM ad and its similarity to *Titan* said only: "I can neither confirm nor deny . . ." The British magazine *Flight,* however, in its December 7 issue reports that *Titan* is a two-stage weapon with the sustainer rocket mounted directly over the booster. General indications are that the length of the missile mounted and ready to fire approximate 100 feet with the diameter of the booster maybe 10-to-12 feet; that of the warhead and final stage, 6-to-8 feet. Fueled weight is undoubtedly well over 100,000 pounds.

These reports plus the fact that AF may shelve the *Navaho* project in order to be able to concentrate even more on ICBM development indicate that the state of the art is a lot more advanced than most people thought it would be two or three years ago. The advanced state of the ICBM's could be the main reason Defense Secretary Wilson is so willing to limit research and development money.



Puzzling on the accompanying artist's conception is the clear indentation in the missile body near the tail section, unless it is that the aerodynamic guidance fins are dropped off before the booster has burnt out.

Also, the warhead is similar to pictures of Martin test cones for the Vanguard satellite launching project. More probably, Titan's nose cone will be a compromise between the blunt, high-drag-to-weight ratio configuration and the sharply tapered high-speed reentry design, i.e., both tapered and blunted.

Flight reports that Aerojet-General Corp. is responsible for *Titan's* stage one motor, with Reaction Motors, Inc., responsible for chambers. Nothing specific has been released as regards the thrust of the first stage booster, but it is reported to be on the order of 250,000 pounds, or at least that's some kind of design target.

Another indication of the advanced state of the ICBM programs is a recent report that considerable Convair *Atlas* staff are moving to Patrick AFB "permanently." Meanwhile, Martin's rocket engine and systems test facility at Denver, Col., has reached an advanced stage of completion.

It begins to look increasingly as though AF placed its bets well when it contracted for ICBM development.

TITAN?

news briefs

NORTH AMERICAN AVIATION now has three IBM 704 electronic data processing machines in operation to help speed research and development of supersonic aircraft, missiles and rocket engines. Two are at its main Los Angeles plant, the third at NAA's Rocketdyne Div. at Canoga Park, Calif.

BENDIX AVIATION CORP. has acquired assets of Sheffield Corp., Dayton, Ohio producer of precision gauging and measuring instruments. Current Sheffield sales run about $24 million annually.

TEXAS INSTRUMENTS, INC., transistor producer, expects final 1956 earnings will reach $2,100,000, up almost 30% from $1,582,000 in 1955. Sales are estimated at $44 million against $28,685,000 last year.

ELECTRONIC CONTROL SYSTEMS, INC., Stromberg-Carlson affiliate, has leased a fourth building in West Los Angeles area at 2205 Stoner Ave.

ACF INDUSTRIES, INC. earned $3,758,000 on sales of $129,589,000 for its first six months ended October 31 compared to $3,875,000 on sales of $117,274,000 for like period last year.

AUTONETICS DIVISION, North American Aviation, Inc. has purchased a 15½ acre plot of land adjoining present division headquarters to be used for future expansion.

DOUGLAS AIRCRAFT CO. and United Auto Workers have agreed on an initial contract covering workers at its Charlotte, N. C. *Nike* missile plant. It expires early in 1958.

AGREEMENT SIGNED between Hughes Aircraft Co. and Aircraft Industries Workers at company's Culver City plant calls for wage increase of 7¢ to 15¢ an hour. It also provides hike next year of 6¢ to 11¢ and institutes a cost of living clause. Hughes recently signed a similar contract with International Assn. of Machinists at its Tucson plant.

SMALL BUSINESS WON at least a half-share of the $624,700,692 in purchase orders issued by North American Aviation during its fiscal year 1956. Some 11,028 firms having less than 500 employes each received contracts worth $312,399,366, up from $275,725,886 in 1955.

CONVAIR ASTRONAUTICS new $40 million plant being built near San Diego for *Atlas* intercontinental ballistic missile production is reported on schedule. Engineering laboratory is the first building slated for completion.

LITTON INDUSTRIES registered sales of $6,230,000 for quarter ended October 31, exactly double the $3,115,000 for same period in 1955. Profits were $401,000 compared to $212,000 a year ago. Litton backlog reached $36 million and assets exceeded $13 million.

INTERNATIONAL NICKLE CO. OF CANADA, LTD. has announced a joint government-company financed $175 million expansion which will increase its annual output approximately 50% by 1960. Firm recently raised nickle prices 9.5¢ per pound to 74¢, first hike since November 1954.

Rocket Trends

By Erik Bergaust

Army still hasn't said anything about their record-breaking rocket flight four months ago. A favorite topic of conversation at the American Rocket Society annual meeting in New York a few weeks ago, it appears Drew Pearson predicted last July the Army was about to shoot a missile some 3,000 miles. The firing took place September 20. *Life* magazine was first to tell the story (October), newspapers picked it up and people started to talk about the venture. The outstanding Army missile firing was discussed in barber shops at Cocoa Beach near Patrick and at Huntsville and wherever rocketeers get together.

The public might have been led to believe that this Army missile was the *Jupiter* prototype. However, industry people refer to the record-breaking missile as a *Jupiter* "C," not a *Jupiter* IRBM. In its November write-up m/r indicated the *Jupiter* "C" consists of a modified *Redstone* as a booster, a cluster of scaled-down *Sergeants* for the second stage and another scaled-down *Sergeant* cluster for the third stage. The *Jupiter* "C" launched on September 20 supposedly went as high as 650 miles, according to some—others say 680 miles. Maximum velocity of 15,000 mph and range of 3,300 miles have been mentioned. It remains a strange phenomenon—if these figures are true—that the Army will not claim officially the world's speed and altitude records for rockets.

Meanwhile, the Air Force is closing in on the Army ballistic missile lead. Big payoff for Air Force missile planners stems from their wisdom in running two parallel ICBM programs—*Atlas* and *Titan*—and using the skillful planning experience of ARDC. Result: Air Force *Titan* and *Atlas* are far more advanced than was contemplated a year ago. We predict the recent Army ballistic rocket publicity will look like peanuts compared to what Air Force will get, for only the Air Force can send a rocket to the moon . . . This will happen sooner than you think . . .

Beyond that Air Force is understood to be thinking in terms of nuclear-powered rockets. And the airmen soon will learn that this earth of ours is much too small as a proving ground for such high-punch stuff. So the United States Air Force might have to become the United States Space Force—whether anyone else likes it or not.

So you'll hear more and more about the Air Force planning to send a rocket to the moon. And you'll be hearing more about the fact that we're racing the Russians in this respect too. Some ace WDD planners and top notch scientists will see to it that we get there first, we predict. Furthermore, we have a feeling one particular name, eventually, will stand out in this connection—that of Krafft A. Ehricke. When we asked a high-ranking AF officer recently whether the AF was interested in space flight, he said: "Not only are we interested, but note that when man goes into space, it will be an air force venture, and the guy in the driver's seat will be an Air Force pilot!" There's no question the AF is a logical choice for pursuit of the space flight goal. Nevertheless, we feel certain the Navy wants to get into the act too . . .

Washington Spotlight

By Henry T. Simmons

The Navy has assembled a team of four top contractors to carry out the development of the Fleet Ballistic Missile, this column has learned. Responsible for the airframe is the Missile Systems Div. of Lockheed Aircraft Corp. Aerojet-General Corp. has been assigned the propulsion unit, while General Electric Co. and Massachusetts Institute of Technology will work on the guidance and fire control features.

•

Selection of the contractors means that the Navy will be relatively little affected by the transfer of control over the development of the *Jupiter* IRBM from the Army to the Air Force. Although the *Jupiter* was originally set up as a joint Army-Navy project, the sailors some time back worked out a revised program which called for a solid rather than a liquid-propellant weapon and accordingly proceeded with its development. Thanks to this preliminary effort, it will only be necessary to increase the scope of some of the earlier work to assure the Navy of a full-fledged FBM development program of its own.

•

Fate of the Army Ballistic Missiles Agency and its cadre of *Jupiter* scientists and contractors may well prove to be one of the knottiest administrative problems in the entire missile picture during the next few months. In theory, the Air Force is free to finance continued development of the weapon after next July 1, but Pentagon insiders are dubious about the prospects of this in view of the pinch on funds available to the Air Force for research and development. They believe the airmen will abandon almost all of the *Jupiter* work, with the result that an experienced scientific and industrial team will be lost. But so far, no one in the administration has come forward with any solution to the problem (see m/r editorial page 7).

•

The simplicity and low cost of the infra-red guidance system of the Navy's *Sidewinder* air-to-air missile has so impressed the Air Force that it has ordered an IR version of the Hughes *Falcon*. Unlike their radar-guided counterparts, the heat-seeking *Falcons* will require no external fire control. Since most of the aircraft which might use them will come equipped with a half a ton of radar fire control apparatus, it appears likely that the new birds will be mixed in with radar *Falcons* to offset countermeasures.

•

Navy budget request for Fiscal 1958 includes funds to assure a "modest growth" of the Point Mugu missile flight test range off the coast of California. It will provide for vessels to serve as down-range tracking stations as an interim measure, although ultimately the range might extend to the Galapagos Islands and beyond.

•

So-called "zip" fuels may provide a spectacular performance boost for the Navy's air-breathing missiles when they become available. Although the high-energy fuels are presently slated for ramjet-powered birds, it is likely they will also be feasible for turbojet-powered weapons. Their big advantage: a 40% boost in fuel energy for a given volume, with consequent range and speed increases. The Navy has started work on a $33 million zip fuel production plant at Muskogee, Okla.

book reviews

Reference Data for Radio Engineers. *By International Telephone and Telegraph Corp., 4th edition. Published by IT&T, Publication Dept., 67 Broad St., New York 4, N. Y. 1121 pp. $6.00.*

An improved and expanded edition of a reference data handbook which has been popular since 1943. The book was designed to save time spent by radio engineers in finding data to solve a wide variety of problems needing equation, curve, table and monograph information.

The new version contains new and completely revised information to meet current requirements in the radio engineering field. These include such subjects as semiconductors and transistors, helical antennas, nuclear physics, scattering matrixes in waveguides, etc. A tremendous quantity of data is packed in this one volume. H.P.S.

Jane's All the World's Aircraft 1956-57. *Compiled and edited by Leonard Bridgman. Published by McGraw-Hill. $25.*

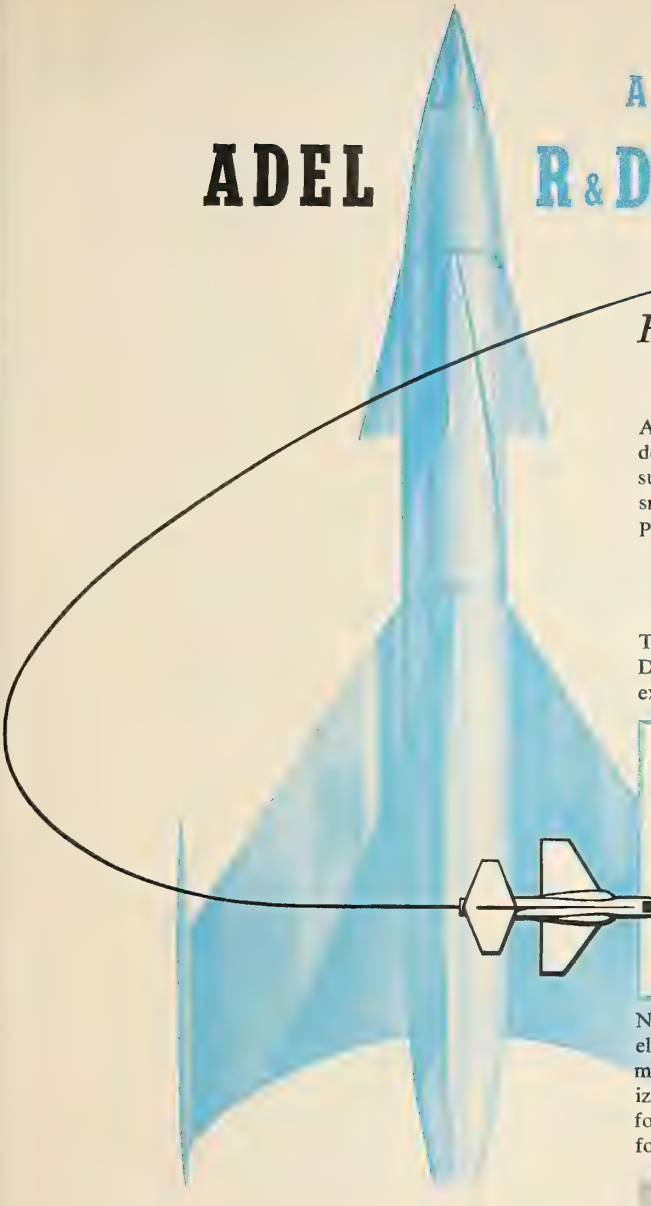
For the first time in this renowned aviation annual there is a missile section. Mention is made of the Russian T-7A medium-range artillery rocket, a SAM developed from the German Rheintochter, "an improved V-2 type" ballistic missile, a winged jet-powered medium-range, bombardment missile, and the T-4A supersonic glide-bomb.

The missile section describes Vanguard and shows it diagramically. USAF, US Navy and Army designation systems are explained and all Western missiles are tabulated on four pages faced by the same number of familiar photographs. Although 42 U.S., 13 French, 10 British and one Swiss operational and research missiles are listed. The table includes the following items which the British Ministry of Supply states are not official:

(1) Armstrong-Whitworth Sea Slug, Royal Navy SAM, has four concentric booster rockets, measures 20 ft. long, resembles model shown in company's supersonic tunnel and has English Electric guidance system.

(2) A de Havilland infra-red AAM is to be standard for the Royal Air Force. It resembles a test vehicle revealed at the 1954 SBAC Farnborough show.

(3) English Electric SAM is a beam-rider with either Napier liquid rocket or Napier ramjet and Marconi guidance.



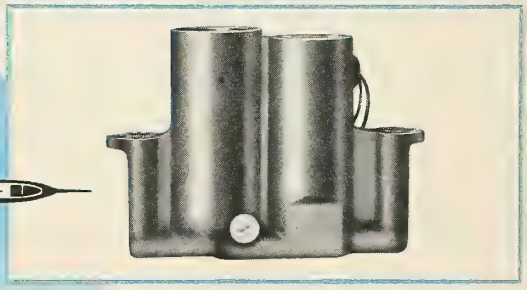
(4) Fairey has an enlarged development of the Fireflash AAM, 10 ft. long (without booster) which was the missile shown anonymously at the 1955 Farnborough show.

The 1956-57 edition of Jane's carries 13 more pages than did the 1955 volume on U.S. aircraft (121 in all)—more than one-third of the total and double the second entry, the United Kingdom. The Soviet Union is up from nine to fourteen pages although there is nothing not previously published elsewhere.

This is the 47th issue of Jane's and it follows close upon the award of a Paul Tissandier diploma by the FAI to Leonard Bridgman for his work as compiler and editor for 36 years. These diplomas have but rarely been accorded to aviation writers: Wayne W. Parrish, president and publisher of m/r received one last year, and only one other British writer—the late C. G. Grey—has ever been given one.

ADEL

ANNOUNCING ANOTHER R&D ACHIEVEMENT



New Electric Motor Driven Hydraulic POWER PACKAGE For Guided Missiles

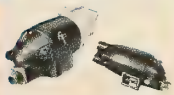
ADEL has long been engaged in power unit research and development programs for guided missiles and piloted supersonic aircraft. This has resulted in the production of small, lightweight, reliable and self-contained auxiliary POWER PACKAGES.

POWERFUL • SMALL • COMPACT • RELIABLE
LIGHTWEIGHT • SUPERIOR PERFORMANCE

These power units permit wide latitude in systems design. Developed, qualified and produced to meet or exceed exacting specifications.

New in concept and development, envelope incorporates electric motor, hydraulic pump, valves and reservoir, all manufactured in our own plant. Proven through specialized, advanced engineering under complete, in-plant performance and environmental testing facilities required for ever higher product quality.

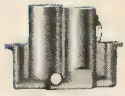
REMEMBER . . . ADEL can design, develop and manufacture other airborne components to meet your requirements. Investigate the complete ADEL facilities for qualification testing which can contribute greatly to accelerate the progress of your engineering development projects.



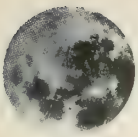
BURBANK, CALIFORNIA • HUNTINGTON, WEST VIRGINIA

ADEL designs and manufactures aircraft products in the following major categories:

Hydraulic & Pneumatic Control Equipment



Anti-Icing, Heater & Fuel System Equipment



Engine Accessories

Hi-Temp Manual & Solenoid Operated Valves

Electric Motor Driven Hydraulic Power Packages

Missile Miscellany

This page, to be a regular m/r feature, considers itself a kind of swap-shop for ideas. Like the mind, it abides no limits to its scope. Its objects are manifold. It's a meeting and mixing place for ideas, off-chance remarks and queries that might otherwise pass unexamined. But mainly, it aims to keep people thinking.

★ ★ ★

Shot through with bitterness, this remark from a man on the Jupiter team at Redstone: "We're all getting two-to-three-job offers a day from industry...good pay, too." From a Bomarc engineer: "Bust up the von Braun team, and U.S. ballistics missiles lose five years."

Then, at dinner the other night, this page heard a liquid propellant salesman toss out: "What the missile business needs is its own basic R&D agency, free from profit motives, politics, interservice squabbles and annual budget fights. Maybe Congress ought to take ABMA from Defense and give it protected status like NACA."

★ ★ ★

Space is neither "free" nor "empty." Plus all the bits and pieces of matter flying about, it's a massive energy spectrometer, including not only light and heat but also strong magnetic, electrical and gravitic (and who knows yet what other) energy gradients.

In the mellower hours of the annual ARS meeting, an aerodynamicist asked: "Why don't we ride these gradients? Carry just enough fuel to gather and convert space energy for propulsion—like a heat pump uses comparatively little power to concentrate a lot of vagrant outdoor heat inside where it'll do some good."

And a quip: "Make Newton's apple fall up, as well as down." But out of the past, this comment by Nobel prize winner Robert A. Millikan (founder of Cal. Tech.) to a student in 1922 is more provoking: "Man will discover the secret of gravity in work with very high voltages and heavy masses..."

★ ★ ★

Some recent unofficial Navy reasoning this page jotted down goes thus: "Return TACAIR to Army; perfect the pilotless interceptor; make MATS an independent all-service operation; and after ICBM kills off SAC, you certainly won't need a whole T. O. of men in uniform to carry out White House orders for an intercontinental count-down."

★ ★ ★

This page feels there must be some mistake but: Navy missed a publicity bet when it didn't claim World War II's sonar-directed torpedo as the country's first guided missile. And it heard an AF planner and programmer say Army is "very happy" with the now-famous November Memorandum wherein AF trades Army even-Steven, Talos for Jupiter.

Gnat Rate Gyro
Shown actual size

GOLDEN GNAT

Miniature Rate Gyros for Missiles and Aircraft

Here is a precision, minature rate gyro. It's tiny . . . measures only 1 inch in diameter and 2¼ inches in length. It's rugged . . . withstands 100G shock and 10G vibration to 2,000 cps. It has a record of proven performance.

Even under the most severe environmental conditions the Golden Gnat will perform as required. To make this possible many unique design details have been incorporated. One such detail is the Gnat's *gold plated* steel housing for improved corrosion resistance and positive hermetic sealing.

Wherever the need exists for high performance miniature rate gyros such as for autopilot stabilization in missiles and aircraft, antenna stabilization and fire control applications, the Golden Gnat is ideally suited. #1 Safety Factor for Jet Engines . . .

the ONLY Tester for *EXACT HEAT & R.P.M. MEASUREMENT!*

JETCAL analyzer

Tests EGT System Accuracy to ±4°C at Test Temperature

(functionally, without running the engine)

Tests RPM Accuracy to 10 RPM in 10,000 RPM (±0.1%)

This NEW "J" Model *JETCAL* contains NEW . . .
1) Takcal, 2) "Ta'Pot" Potentiometer.
3) Ruggedized Light-Beam Galves,
4) Test Circuits.

Two of the most important factors that affect jet engine life, efficiency, and safe operation are *Exhaust Gas Temperature (EGT)* and *Engine Speed (RPM)*. Excess heat will reduce "bucket" life as much as 50% and low EGT materially reduces efficiency and thrust. Any of such conditions will make operation of the aircraft both costly and dangerous. The *JETCAL Analyzer* predetermines accuracy of the EGT and (interrelatedly) Tachometer systems and isolates errors if they exist.

The *JETCAL* is in worldwide use. Used by U. S. Navy and Air Force as well as by major aircraft and engine manufacturers. Write, wire or phone for complete information.

ANALYZES JET ENGINES 10 WAYS

1) The JETCAL Analyzer *functionally* tests EGT thermocouple circuit of a jet aircraft or pilotless aircraft missile for error *without running the engine or disconnecting any wiring.* GUARANTEED ACCURACY is ±4°C. at engine test temperature.
2) Checks individual thermocouples "on the bench" before placement in parallel harness.
3) Checks thermocouples within the harness for continuity.
4) Checks thermocouples *and* paralleling harness for accuracy.
5) Checks resistance of the EGT circuit *without the EGT indicator.*
6) Checks insulation of the EGT circuit for shorts to ground and for shorts between leads.
7) Checks EGT Indicators (in or out of the aircraft).
8) Checks EGT system with engine removed from aircraft (in production line or overhaul shop).
9) Checks aircraft TACHOMETER system accuracy from 0 to 110% RPM with guaranteed accuracy to within ±0.1% in the operating range.
10) JETCAL Analyzer enables engine adjustment to proper relationship between engine temperature and engine RPM for maximum thrust and efficiency during engine run. (Taking off or Mating)

ALSO *functionally* checks aircraft Over-Heat Detectors and Wing Anti-Ice Systems (thermal switch and continuous wire) by using TEMPCAL Probes. Rapid heat rise . . . 3 minutes to 800° F. Fast cycling time of thermal switches . . . 4 to 5 complete cycles per minute for bench checking in production.

missiles and rockets
MAGAZINE OF WORLD ASTRONAUTICS

Navy Missiles Roles and Missions

By Rear Adm. James S. Russell, USN

Chief, Bureau of Aeronautics

THE IMPACT of guided missiles and rocket power is bringing basic and far-reaching changes to naval aviation. Changes in tactical concepts, changes in equipment, and changes in the efficiency with which the mission is performed are operational facts today. More is on the way.

Although these implications of guided missile and rockets to the air systems of the fleet are already immense, they are not yet seen as the total end in themselves. Although their influence upon concepts of sea-based airpower is almost immeasurable, they will in the foreseeable future fit into basic patterns of Navy air requirements.

These exciting new families of unmanned weapons will extend the striking and defensive arms of naval aviation in the same way that aviation itself extends the arm of total seapower, including surface and undersea forces.

We should perhaps note the past before discussing future influences of missiles and rockets on naval aviation.

The Navy has consistently advanced the art of missilry and rocketry from the start. Rocket power was first applied to naval aircraft as the well-known Jet-Assisted-Take-Off (JATO). Historically compelled by the restricted space available on ships at sea, the Navy has pioneered the development and use of assisted take-off devices, such as the catapult and JATO.

Today JATO is used more than ever, and its use in the future is assured, to extend our launching capabilities and literally to get us out of tight spots. A seaplane flying across the United States in 1944 was forced down in a pond. It was flown out with JATO.

The Navy's initial capability to deliver the atomic bomb—before we had our modern planes and when the bomb was an awkward gadget—depended on a jet-assisted-take-off. Currently, all our seaplanes and heavy attack planes have provisions for JATO use.

During and after World War II, development brought turbo-jet and rocket engines and with them aircraft of greatly increased speeds and altitudes. Flight potentials went beyond the testing capacity of existing wind tunnels. To obtain design information and data in this era of high speed and high altitude flight, research vehicles, both manned and unmanned, were powered by rockets. These projects were joint service efforts among the Air Force, the National Advisory Committee for Aeronautics, and the Navy. A series of rocket propelled airplanes and smaller free flight research vehicles were flown in a program participated in by many interested agencies. For instance, the Bell X-1 flown by the Air Force was powered by a Navy-Reaction Motors, Inc., developed engine which delivered 6000 pounds of rocket thrust.

The Navy's Douglas SKYROCKET, the D558-2, another rocket-powered research aircraft, was clocked at 1065 knots at 79,000 feet, back in 1951.

Highly instrumented rockets, with or without a pilot, flying from such different places as Muroc, California, and Wallops Island, Virginia, have augmented and confirmed a usable pattern of much needed data.

Today's high performance airplanes owe much of their success to the knowledge gained from the flight of rocket-powered research vehicles.

Many Firsts For Navy

There are many "firsts" in missile development on record which are the direct result of the efforts of the Bureau of Aeronautics. Among these are the first surface-to-air missiles known to have destroyed a target aircraft, the *Lark;* the first all-weather air-to-air missile system to become operational, the *Sparrow I;* the first ship-launched surface-to-surface missile to become operational, the *Regulus I;* and one of the first guided missile test and evaluation centers, the Naval Air Missile Test Center at Point Mugu, California.

In all of this past effort, the aim has been to take the conjecture out of design, to experiment and document, to refine and improve, and to put missiles and rockets to work on a practical basis.

To realize the advances, one only has to look at some of the early contractual documents. So little was known about the art as little as fifteen years

ago that development contracts were written loosely, and in vague, nebulous terms. Combustion chamber geometry was more "plastic art" than engineering. Performance calculations were educated guesses. In both guided missiles and rocket power applications the flight article was largely a product of fortunate estimates and the particular skills of artisan machinists.

Today's development contract is a good indicator of the progress achieved; specifications are called out with engineering precision and with a scientific know-how which reflects the testing and documentation experience typical of an established science.

In discussing the role of unmanned vehicles in future fleet aviation, we must also assess the present.

Within the organization of the Navy Department, the work and responsibilities for Navy missilry is shared between the Bureau of Aeronautics and the Bureau of Ordnance. Each of us has defense missiles—those used to destroy attacking aircraft, and attack missiles—those guided to enemy ships, submarines, and shore bases.

Modern rockets as weapons were founded, nurtured and firmly established in our arsenal by the Naval Ordnance Test Station (NOTS) at Inyokern, or China Lake, California. The present staff of over a hundred scientific personnel, plus many engineers and technicians grew from a cadre originally started by the Navy's Bureau of Ordnance at the California Institute of Technology. At China Lake the rocket is supreme. There it is the objective and also the means to the objective.

The Naval Ordnance Test Station has, as a result, an outstanding know-how in rocketry. In their work they recognize that the weak point in the ballistic rocket system was accuracy. The result of their staff work has been a milestone in air defense progress—a five inch rocket with a small guidance section added. Having been born in the desert and quite deadly, it was named the *Sidewinder*. Possibly because of its novel conception in the field of missilry, *Sidewinder* has two characteristics which stand out in this day of complex technology and complicated logistics. It is **simple** and it is **cheap.** There are an unbelievably small number of parts and a power supply weighing less than an ounce. It is the only missile whose cost compares to the price of a load of aircraft cannon bullets.

To round out the Navy air-to-air missiles, the Bureau of Aeronautics has developed and put into the Fleet the *Sparrow* missile. You might ask "Why have the *Sparrow* if we have an economical and effective *Sidewinder?*" It is not a question of buying a Ford when you already have a Chevrolet. We are faced with the problem of having to be ready for anything and everything which an enemy might bring to bear—and to date no missile does everything.

The *Sparrow* line of missiles is incorporated in air weapon systems involving transonic and supersonic interceptors. In modern task force operations, the fleet's air defense is heavily dependent upon the ability to destroy attacking aircraft at long ranges and under all weather conditions.

Sparrow missiles have added considerable reach to the intercepting aircraft, under blind firing situations, and from a wide variety of firing angles. Further developments underway will give *Sparrow* increased capability for breaking up enemy air attacks at even greater distances, and again under all weather conditions. Both *Sparrow I* and *Sidewinder* are operational.

Many think that missiles will supplant manned aircraft. Be that as it may, it is very clear that in many areas missiles will certainly take over. The Navy attack missile, the *Regulus,* is a good and possibly first example of a missile becoming a partner rather than a tool of conventional aviation. This missile can carry a nuclear warhead and can be launched from ships. In fact, we have ten ships, including submarines, ready now.

The *Regulus* can be best described in the words of Chance Vought, its manufacturer, "It takes shore leave 500 miles at sea." Great mobility in dispersing and in hiding the launching ship in the immense waterways of the world provides a strongly desired element of surprise in the adaptation of *Regulus* to seagoing vessels.

There was a touch of genius involved in *Regulus* when someone conceived the idea of equipping it with landing gear in lieu of warhead during the development program—thus tremendously decreasing the program cost, the development time, and the cost of training. A short while ago at Chincoteague, a *Regulus* was boosted into the air with two rocket motors; then, after a programmed flight, it returned to the base for the fifteenth time.

The supersonic *Regulus II,* which is currently being tested, is also using wheels so it can return to be studied and analyzed and to fly again. It is a pity that we cannot shorten and cheapen all of our missile programs by recovering the spent birds intact.

Missiles also extend and complement the air defense capabilities of ships. Navy missiles devoted to this purpose are the *Terrier,* boosted into flight and sustained by rocket engines; and the *Tartar,* in which a single motor does both the boosting and the sustain-

James S. Russell
Rear Adm., USN

Young (53), energetic Rear Admiral James S. Russell is a man well suited to his job. To intelligent imagination and tolerance he adds a long and varied career in the Navy, including combat duty in the Aleutians, Palau, Philippine Islands, Iwo Jima and Okinawa. Since the war he has commanded some of America's biggest aircraft carriers.

In addition, Admiral Russell has a Bachelor of Science from the U.S. Naval Academy and a Masters degree from California Institute of Technology. He is a fellow of the Institute of Aeronautical Sciences and is vigorously optimistic over the Navy's future in the age of missiles and rockets.

He is intensely interested in the transition from aeronautics to astronautics, and in fact at the recent American Rocket Society meeting in New York predicted that practical nuclear propulsion for space flight would come sooner than we expect (m/r, Dec., p. 29). The Admiral, however, is officially silent on whether the roles and missions responsibility for patrolling the infinite seas of space should fall to the Navy or Air Force.

Out of its deck hangar and ready to go, REGULUS I gets a final check before being launched from the deck of the Navy missile submarine USS TUNNY.

ing. These surface-to-air missiles are quite a bit different from those one sees at our laboratories and testing grounds. There is no count-down, no waiting for computations. One presses a button and in rapid succession and with complete automation, the missiles are fed from the magazines, loaded, and then fired by an electronic device.

The cruisers *Boston* and *Canberra* are now in service firing *Terriers*. We are building our first *Talos* ship to be ready in '58. *Tartar* will be put on ships in the 1957 building program. Five years from now, we will have at least eight *Talos* cruisers, twenty-two *Terrier* ships, and seventeen *Tartar* ships.

Another air-to-surface missile is the *Petrel*, developed by the Navy's Bureau of Ordnance. It is designed to attack ship targets, and combines the features of a guided missile plus underwater torpedo. Attacking aircraft can launch the *Petrel* well out of range of ship defenses without running the gauntlet of conventional flak and machine gun fire.

A large part of Naval air's striking capability is centered around missile-airplane combinations. One of the air-to-surface missiles is designed to give the attack pilot capability to destroy pinpointed targets such as submarines and small shipping. In addition, it has land interdiction capabilities, and can be used in the type of close support work at the front lines, such as knocking out enemy pill boxes and hill-top strong points, which is the particular forte of Naval and Marine aviation.

A new adaptation of guided missiles to air defense is for the defense of large patrol or bomber type planes. Such a missile will have the versatility effectively to seek out fighter and intercept aircraft making runs on the larger Navy airplanes.

Missiles to Replace Bombers

In the basic attack mission of carrier-based aircraft, a general concept is shaping up involving the "stand-off" use of guided missiles. This is anticipating the possibility that the enemy's defenses of industrial and submarine pen types of targets may be so well developed that manned aircraft cannot make a conventional bombing run.

Away from the front lines at sea, or the shooting dynamics of task force air defense and attack missions, a most important work has always been fostered by naval aviation. This is the design and use of target drone aircraft.

The relationship of the automatic airplane to the guided missile is fairly obvious. Guided missiles and target drones are blood cousins. There has been much interchange and two-way flow between the design arts in both machines. This carry-over of knowhow and technique has been of mutual advantage to each.

We in the Bureau of Aeronautics consider the target drone of great importance, first in providing a reasonably fast and maneuverable target for missile test firing and for maintaining combat readiness at sea, and secondly for the techniques in the art of drone design which are applicable to missile design. Although some say that it's not the most glamorous part of the business, the true value of the target drone cannot be overemphasized.

Navy Missile Budget Up

A revealing insight as to the growth of guided missiles and the increasing weight being placed upon them by the Navy is seen by a quick look at the administrative side of the picture. In the past six years, the funding for research and development, test and evaluation facilities, and procurement of flight articles have all steadily increased. The proportion of this increase is much greater than the increase for like considerations of conventional airplanes over the same period. In the fiscal year 1951, the Navy budgeted $5 million for guided missiles. It is estimated that in fiscal 1957 $209 million will be available. This is a rate of increase of almost 21 to one. In conventional aircraft, the increase rate has been roughly only three to one, for the same period.

Perhaps the real proof of the importance of missiles to national defense is the fact that a Special Assistant to the Secretary of Defense was recently appointed to administer the overall guided missile program.

While on the thought of overall administration it might be well to point out that most of the considerations given to guided missiles and rocket applications fit well into the normal scheme of things for those in the airplane business.

Indeed, a thesis could be fashioned drawing out the similarities of airplanes to guided missiles or vice versa in all the design, manufacture and procurement phases. Much of the procedure and knowhow applies in either case.

There are inherent differences, of course. For one thing, the missile can

be designed for optimum flight conditions. Since it has a boost for take-off, and is usually thought of as expendable, the design penalties for carrier take-off and landings, and round trip radii are not there. Neither is the guided missile subject to the ills of the human pilot factor; and conversely, neither does it have the advantages of the human brain.

Military aviation is under constant pressure to maintain or gain advantage over potential enemies. This has forced aircraft up higher and faster, until one enters the true realm of the rocket engine. With a practical air defense mission to perform, the aircraft must have reasonable endurance and meet other design parameters. The manifest answer is to blend the capabilities of the turbo-jet and the rocket engine in a combination power plant.

The future of the unmanned air vehicle in the fleet must be viewed from the vantage point of all these things: the past, those presently operational, and how we manage administratively.

First, we expect to see, as far out as the next fifteen years, an orderly and progressive improvement in all the guided missile types that are now operational. This would mean that basic missions of the guided machine would remain intact, such as air-to-air, air-to-surface, surface-to-surface, and surface-to-air. In all those categories, better guidance, longer range, greater reliability, and more effective warheads tailored to the target will be the trend and the objective.

Secondly, the increased use of guided missiles of better performance will to some extent affect now standard Naval air tactical concepts. The exact extent can only be determined in actual operation at the time and place of a missile's introduction into the fleet.

Then, too, for any bold and sweeping change in fleet air defense, for example, we must look to the enemy's capability. If he comes up with substantial stand-off missile potentials, then we must project our intercept capability to greater distances accordingly. Here longer range air-to-air missile armament for our own interceptors would be in order.

Or, from within our own family, if the surface-to-air capability of our task forces is good, then these missiles will push farther out the fighter and intercept screens, requiring better range in both planes and missile armament.

Mobile Force Immune to Ballistic Missile

At present the Navy is working on development of a 1,500 mile missile which we can call the Fleet Ballistic Missile. I am sure that the ballistic missiles, as well as the earth satellite rocket now nearing its first development flights, *Vanguard,* mean to many of us that the door to rocketry has swung fully open and that we are on the threshhold of space travel.

Research rocket VIKING-13 a few seconds after leaving its mat on a preliminary IGY research flight from Patrick Air Force Base last month. The VIKING reached 125 miles.

To the Navy, entrusted for its part of the National Defense, the Fleet Ballistic Missile fits in another picture. Whether it be a weapon of retaliation or a deterrent to attack, the Navy will be prepared to launch it from an infinite number of locations—at sea within reach of most any potential target in the world. Conversely, the mobility of a Naval force renders it relatively immune from attack by the ballistic missile, leaving the advantages of this overwhelming retaliatory weapon to the Naval force.

Any conjecture as to the possibility of guided missiles taking over the job of task force air defense completely must be tempered by an awareness of the state of the art in missile design. The "when and if" of an all missile air defense is the when and if of a very long range ballistic missile which has the proven capability of successfully attacking moving sea targets.

Should such a ballistic missile appear, it is not unreasonable to anticipate that manned aircraft would give way certainly, for this element of defense, to anti-missile guided missiles.

For the future, the man in the laboratory today increasingly assumes the role of the man behind the gun. More than ever before the outcome in another war would depend on what went on in a test-tube, betatron or the quiet of a mathematician's study three, five or ten years before.

The age of missiles and rockets is the age of the scientist and engineer. Progress in the development of new materials, fuels and design concepts continues to be good, better in some cases than we had anticipated two or three years earlier. The real advances, of course, come with major technological break-throughs as well as in the difficult-but-vital day-to-day development of safe, reliable operational missile systems. In the latter, the Navy has done well. In the case of the former we, the U.S. as a whole, excell but we can always do better by improving cooperation and liaison between three services, other agencies of Government, private universities and industry ★

U.S. Navy Missile Arsenal

Manufacturer	Designation	Powerplant	Remarks
		SURFACE-TO-SURFACE	
Chance-Vought	REGULUS SSM-N-8	1 Allison J33-A-18A jet plus two Aerojet-General solid rockets	In service; nuclear warhead, command or self-homing guidance, subsonic, range over 500 mi.
Chance-Vought	REGULUS II	Prototypes powered by Wright J65; production models get GE J79	In production; supersonic.
Lockheed; GE; MIT	POLARIS	Aerojet solid propellant	Under development; intermediate-range fleet ballistic missile; can be launched from underwater.
McDonnell	TRITON	Zip-fueled ramjet + booster	Under development: supersonic; Mach 3.5; over 80,000 ft.; range 1500 mi.; will fit *Regulus* submarine launching gear.
		SURFACE-TO-AIR	
Convair/Bendix	TERRIER SAM-N-7	Aerojet liquid rocket + solid rocket	In service; beam guidance. Also *Terrier* I and *Terrier* II.
Bendix	TALOS SAM-N-6	McDonnell ramjet + booster	In production; also *Talos* L for AF and *Talos* W for Army. Late Navy developments using zip-fuels to have 300 mi. range; Mach 4.0 speed.
Convair	TARTAR	Allegany Ballistic solid rocket	In production; for destroyers, and other small vessels.
		AIR-TO-UNDERWATER	
Fairchild	PETREL AUM-N-2	Fairchild J44 jet	Under development; anti-submarine missile; launched from aircraft.
Sandia + ?	LULU	?	Under development; air-dropped or surface-launched anti-submarine weapon; atomic warhead.
		AIR-TO-SURFACE	
Eastman Kodak	DOVE ASM-N-4 and -5	?	Under development.
		AIR-TO-AIR	
Douglas, Sperry/ Raytheon	SPARROW AAM-N-2	Aerojet solid rocket	In service; also AAM-N-3 and N-4.
Philco	SIDEWINDER AAM-N-7	Norris Thermador; Hunter Douglas, Hercules Powder solid rocket	In service; infra-red homing. Developed by Naval Ordnance Test Station, China Lake, Calif.

m/r's personal report from . . .

Navy Air Secretary Norton . . .

. . . reveals All-Navy FBM *Polaris* To Be Launched From Nuclear Submarine; Balanced Spending Rise For Navy Missile Program; High Praise for ABMA

Assistant Secretary of the Navy for Air Garrison Norton told m/r's *editor as he sat down for this personal report: "I'm new at the job and really don't have a great deal of experience." His background, however, belies this. Harvard graduate, Certified Public Accountant, reserve Naval aviator and former Assistant CAA Chairman, Assistant Secretary of State, Chairman of the Air Coordinating Committee, Special Research and Development Consultant to the Secretary of the Air Force and U.S. delegate to many international aviation conferences, the Navy's 56-year old Air Secretary has as good a grasp of his responsibilities in his job as anyone we've encountered in Government.* m/r *considers this* personal report *a vital service to the missiles and rockets industry and plans more like it in the future.* The Editor.

Q. Mr. Secretary, what roles do missiles play in the Navy today?

A. The soundness of the planning that we did over five years ago is becoming evident. We now have in service as operational weapons guided missiles in all categories, air-to-air, surface-to-air, air-to-surface and surface-to-surface. In the field of air defense, we have two *Terrier* cruisers. We have just commissioned a *Terrier* destroyer, and we have more surface-to-air missile ships in various stages of completion. These missiles have increased our anti-aircraft range from a few thousand yards to over ten miles. In the realm of air-to-air missiles we have missile-armed fighter squadrons employed in the Atlantic, the Pacific and the Mediterranean. These squadrons are equipped with *Sparrow I* and *Sidewinder.* These weapons increase not only the range at which our fighters can knock down enemy planes, but they permit us to get shots at planes we could not otherwise reach at all, such as those we detect at much higher or lower altitudes. All our air defense weapons are supersonic as they must be to cope with high performance aircraft we may expect to encounter. Anti-aircraft guns are nearly useless against modern aircraft and our airborne guns are becoming very limited in this respect. In the field of offensive missiles we have submarines, carriers and cruisers in both fleets that can launch the *Regulus,* which can carry a nuclear warhead under any weather conditions to targets as much as 500 miles away. The *Regulus,* launched from a submarine, gives us a very powerful capability to attack completely undetected. The *Regulus I* is a transonic weapon, but already we have *Regulus II* flying and that one is supersonic. For attack of surface ships we have the *Petrel,* which when launched by a patrol plane can deliver its payload from so great a distance that the launching plane is not faced with destruction by enemy surface forces.

Q. What about Navy missiles in the near future, say, five years from now?

A. Well, five years from now, we will see very considerable changes in the Navy, not only because our missiles will be faster, more effective and will have longer ranges, but because many of our ships and planes will be missile equipped. In five years, we will have the *Talos* longer-range anti-aircraft weapons in many ships. We will have the *Intermediate Range Ballistic Missile,* the FBM, in operation. We will have vastly improved missiles in all other categories.

Q. You mean to say the fleet ballistic missile will be in operation within five years?

A. That's what we expect.

Q. From submarines as well as surface ships?

A. Well, we have hopes it will be operational off submarines in that period too.

Q. Will you have to build new submarines for that one or can you use existing types?

A. No, we have to build new submarines for the ballistic missile.

Q. That's an acceleration of your program, isn't it? You must have gotten more optimistic quite recently.

A. Yes, we have reason to feel that we are closer to an operational Fleet Ballistic Missile now than we felt we were a year ago.

Q. In that connection, Mr. Secretary, just how does Defense Secretary Wilson's November 26 "roles and missions" Memorandum affect the Navy's ballistics missile program? Does this mean that the Navy will give its FBM development to another company or to a private agency? Or will the Navy continue to work with the Army Ballistics Missile Agency (ABMA) and Jet Propulsion Laboratories in this project?

A. Secretary Wilson's memorandum of the 26th of November of this year applied primarily to the roles of the Army and the Air Force. It restated the policy of Navy employment of all categories of missiles, including the Inter-

mediate Range Ballistic Missile. The Fleet Ballistic Missile has requirements that are unique to the Navy. For example, submarine-launched or underwater-launched weapons have special problems, as you can well imagine. Because of the proximity of crew to launching platform we need safer and extremely reliable missiles. Restrictions as to space and size of our ships affect missile design and of course we have very strange navigation requirements. During the past year and a half the Navy has been studying these missile requirements. As a result of these studies the Navy has now revised its program objective. It is still too early to define the contractual structure that the Navy may employ in this revised program.

Q. The revision that you mentioned indicates that the Navy will go out on its own, rather than work with the Army.

A. Yes, that is correct. However, the Navy hopes to make fullest possible use of the ABMA Huntsville facility. As you know, there's great talent there and we have good hopes of running certain parallel approaches in our programs.

Q. You might give them a contract, then?

A. Yes, but basically the Navy is now free to approach this problem on its own.

Q. You don't contemplate that ABMA will be dissolved then?

A. No. We don't know what the plans are for ABMA, but we do know that it is the intention as far as fiscal '57 money is concerned to carry on the present *Jupiter* program, and we certainly hope that the very real talents and ability available there will continue to be available in some form because we think we can make good use of them.

Q. As of now, then, there is no joint Army-Navy *Jupiter* program?

A. That's correct.

Q. Is the main reason for this the technological differences in the missile itself?

A. Yes, I would say so. What we want is a device that is operational when we get it. We want one we know we can go to sea with and use. There have been breakthroughs in this business, and we have now come upon a configuration which looks very good to us, and which is compatible with sea-launching from both surface ships and submarines. This missile has been named *Polaris*.

Q. You mean under-water launching?

A. Yes. That is a possibility.

Q. Dr. Murphree confirmed some time ago that the Navy was interested in a solid propellants Fleet Ballistic Missile.

A. Yes. There are obvious advantages to it.

Q. Are missiles entirely supplementary in the Navy today, or have they begun to replace other weapons types, such as big guns?

A. The position of missiles in the Navy today is very clear. We are committed to converting the Navy to nuclear propulsion and guided missiles for a large number of our tasks. This, of course, takes time and money, but in order to effectively accomplish our mission we must continue this effort with high priority. It would not be accurate to say that missiles play only a supplementary role, since they are able to do many things which other weapons cannot do. In some cases they will supplement, and in other cases they will replace current armament. However, until we are able to complete the conversion of the Navy to missiles, we will see the old weapons side by side with missiles for a number of years. Guns are being replaced, especially for air defense. In addition, certain of our surface-launched air defense missiles will soon be given the capability of hitting targets on the surface as well as in the air. Then the need for surface guns will be very small. We are already planning missile-only cruisers.

Q. Have you stopped buying big guns—heavy rifles such as 16-in. guns?

A. As far as I know we have, yes.

Q. This applies to aircraft carriers as well as other surface ships?

A. Well, I do know that missile anti-aircraft defense is definitely contemplated for our carriers.

Q. You won't see carriers coming off the ways with 5-inch, 38-cal. guns sticking out of the side?

A. I think those days are numbered. Missiles do pose some structural problems. You've got to have little bigger spaces for the missile launching area and devices than you do for the guns. The question of arming our carriers with missiles may still be one that is not yet fully decided. In other words, there may be some advantages in having missile defense on cruisers and so on, around the carrier itself, although I would think that the carrier would be bound to be equipped with some anti-aircraft missile defense. But the mounting of the missile battery is not necessarily the same problem as the gun battery. Of course, a carrier, as you know, is such a specialized affair and every inch of space on it is so important, both on the hangar deck and on the flight deck, that there is still some question as to how far they go in missile launching on carriers themselves.

Q. Looking into the future a bit, how will roles and missions, tactics and strategies of Naval warfare be changed by the advent and development of whole families of guided missile types? For example, insofar as strategic missions are concerned, do missiles presage the day when the surface carrier groups will be superfluous as a strategic concept? Presumably it will be tactically important for some time.

A. This is looking at the future. The basic mission of the Navy is to control the seas and the air above and adjacent

In five years . . . an operational POLARIS.

We need safer, more reliable missiles.

No joint Army-Navy IRBM program any more.

to the seas. You mention both strategic and tactical missions. I would like to point out that the U.S. Navy has a very important requirement to maintain a strong element of air power capable of conducting strategic bombing of not only sea targets, but land targets of Naval interest. Therefore, carrier air groups will be required for a long time, backed up by land and sea based patrol and heavy attack aircraft. In the event of a non-nuclear war the use of missiles for bombardment purposes will be far less than in a nuclear war. The higher degree of accuracy necessary in non-nuclear war will make the Naval air-striking forces indispensable in any such conflict. In nuclear war, it must be remembered, that all land bases will be extremely vulnerable to enemy attack by long-range missiles, enemy bombers, or sabotage. A mobile task force, in a position which is unknown to the enemy will be a much more difficult target to knock out. It might well be that the carrier task force would be our greatest retaliatory force in the event of a surprise enemy nuclear attack.

Q. The beginning of the incorporation of missiles into the Navy on a wide scale must be raising a number of rather worrisome problems: for example, stability in the trained military work-force. The cost in turn-over (failure to re-enlist) must be much greater in the age of the *Regulus, Terrier, Triton,* etc., than it was in the day of the gun. Does not this become increasingly true now that industry's need for men with the same training is so great? How does the Navy view this problem? What's it doing about it?

A. The introduction of any new weapon or any new device always creates a host of problems. The problem of manpower that you mentioned is a great one to the Navy as it is for all the services. In the Navy we strive to develop missiles which can be operated by our sailors. We have succeeded in this to a large degree. We have no contractor's representatives or PhD's on any of our missile ships but we do need a very high level of skill among our enlisted men. It is remarkable how competent some of our Navy men can become. This, of course, is recognized by industry and we do have a competition problem. Recently the Navy has instituted career appraisal teams that have shown results in pointing out to our men the advantages of making a career out of the Navy. We also hope that some of the studies being conducted on military pay and manpower by groups such as the Cordiner Committee will help us in this problem.

Q. Are there any special logistical problems posed by missiles? If so, what are they? What can industry do to help solve them?

A. The logistic problems that accompany the introduction of missiles to the fleet are not unique but are similar to problems faced with aircraft, electronics gear and other complex machinery. The replacement of missiles at sea pose many technical problems that are being successfully worked out. I might add that the aspects of handling, resupplying and supporting a missile are not neglected until the time we get the missile to the fleet. These factors are given considerable attention from the very inception of a missile program, and problems relating to packaging, maintenance, resupplying, so forth, are solved as the missile is being developed. Industry has been concerned with these items concurrently with the evolution of the missiles.

Q. Would you conceivably reach the point where you would be transferring missiles to ships the way you now transfer oil? In other words, pull a supply ship right up alongside and, under way, sling them across?

A. Oh, I think that is not only entirely possible, it is mandatory. I think the ruggedizing of these missiles, for example, is one of the main features. I happen to be acquainted with the *Terrier* development. That's a remarkable case in point. That missile, when it first became operational was still a very delicate affair which had to be handled with great care. Now, thanks to the use of potting compounds in the missile itself plus much more rugged components, the missile can be handled almost the way you handle a five-inch shell. And this will probably be the general trend. It usually is.

Q. Would you say this concept will apply to all kinds of Navy missiles, the larger one as well as smaller surface-to-air missiles?

A. You mean the concept of making them more rugged? Yes, indeed. We are, of course, trying to produce a weapon here that has a long shelf life and that can be handled under sea conditions, under battle conditions and that can be handled by sailors. All of these things require tremendous inherent reliability.

Q. Do you have any special facilities for inactivating shipboard stores of missiles? All these propellants, which are highly explosive seem to constitute a considerable hazard. Do you have, for example, any special arrangement for dumping these things in case a ship gets hit?

A. I just don't know the answer to that. I should think that it might conceivably be that we at least would have to make arrangements for flooding things.

Q. Are they stored the way you used to store your aviation fuels, in a shell of inert gas?

A. We are trying to get away from these exotic and difficult fuels that require special handling. Of course, liquid oxygen is a dreadful thing to handle under any circumstances, particularly so on shipboard. If you have a good reliable solid propellant that can be stored in the same environment with conventional high explosive, etc., you would still be in pretty good shape, I would think.

Q. Aside from absolute, no-defense weapons like the ICBM, it seems that special evaluation procedures must

Red submarine threat cannot be exaggerated.

In some cases . . . no choice but missiles.

My guess is the dollar curve goes up.

be required to determine when a missile weapons system is "worth more" than a conventional weapons system. First, servicing and firing costs would be one yardstick, for example. Has the Navy formalized this relative evaluation procedure? Can you say in general terms what form it takes?

A. Before answering this question, I would like to take exception to your "no-defense" statement concerning the ICBM. This is an extremely difficult problem, but we are working on it and don't forget that the mobility I mentioned before gives a fleet an all-important passive defense to begin with, in that a moving object is not a suitable target for a ballistic missile. The question of evaluation is extremely important not only from the point of view of costs but from the point of view of whether or not the new weapons system meets the requirements. Let me briefly outline how the Navy gets a new weapons system. First, an operational requirement is issued by the Office of Chief of Naval Operations calling for the development of a certain type of device. This is done only after exhaustive consideration of the problems by both Naval officers and various study groups, either agencies of the Navy, such as the Operations Evaluation Group, or organizations under contract to the Navy. Secondly, when this operations requirement is issued to the technical bureaus telling them what to produce, the bureaus themselves have continuous evaluation programs during and after the development of the weapon. Finally, when the missile is ready for production, it is turned over to the Operational Development Force, which is a fleet unit. This force gives the missile a rugged test under actual fleet conditions but with better evaluation facilities. All these evaluation processes consider costs, manpower required, use of vital materials and so forth. We never build missiles just to have missiles. They must do a certain job and do it better. In some cases, however, we have no choice but to adopt missiles such as in the case of the anti-aircraft missiles I mentioned previously.

Q. Can you give us some idea, Mr. Secretary, just how, over the next few years, the advent of missiles will effect the various titles under Category II (military hardware) procurement? We'd like not only to get some percentage idea of how missile procurement will increase, but also how other things like manned aircraft, surface ships, submarines, electronics, big guns, etc., are expected to vary.

A. This is a question I can answer only in general terms at the present time. I can say that the missile procurement will increase over the next few years. Procurement of weapons displaced by missiles such as anti-aircraft guns will obviously decrease. Weapons supplemented by missiles may decrease in number. Within the available funds, as determined by higher authority, we will do our best to procure and maintain the best balanced force possible for carrying out the Navy's missions and tasks, At the present state of the art, there are too many variables involved to state the exact form that such a force will take.

Q. Air Force estimates 35% of their budget will be for missiles shortly. How does the Navy compare?

A. I'm fairly conversant with Benny Schriever's activity in the Western Development Division and what's involved there alone. And it's a fantastic effort. Of course, there you have the entire ICBM program and one of the ultimate IRBM programs. I would think that at least over the immediate future, the next two or three fiscal years, that the Navy's missile percentage would not be as high; however, you do have to look down the road a little bit, and you come to the submarine missile program, which is an IRBM program. Taking submarines and missiles altogether, they will represent a very substantial percentage of the Navy's total money. The Navy is working along, you might say, a triple threat program here, of seaplanes, missile launching submarines and fast carrier task forces, and I would think that looking further into the future, it is unlikely that any one of those programs would be more than a third of the total over a period of years.

Q. Will the FBM subs be atomic submarines?

A. Yes, nuclear propelled.

Q. Just looking at the budget generally, looking at missiles, their striking power, or whatever term you want to use—do you think you will get more punch per budget dollar? Or do you think your budget is going to go up sharply also?

A. That's a very hard question to answer. It is one that Bob Lovett was greatly interested in when he was Secretary of Defense. He had a number of studies cranked up to try and find out whether we were heading into a fantastically high military cost, as some people said, or whether we were actually, by virtue of all the new developments, coming to a point where the curve would go down. My general impression is that the curve is going up and will continue to go up. The complexity of these weapons is so tremendous that even though one weapon can deliver, for example, the entire explosive force which was exerted in World War II, it doesn't follow that you reduce your defense dollar. My personal view is that the defense dollar will continue to increase as long as we have to have defense dollars at all.

Q. Will missiles alone have any material affect on the number of men under arms, all other things being equal?

A. I believe the introduction of missiles to the fleet will have negligible effect on total manpower requirements in the Navy. If we resort to weapons of greater efficiency, we may possibly need fewer fire control units. However, the complexity of the missile systems may require a few more people. In effect, I see little change in total numbers, rather, a reorientation in the employing of our men. Our problem is one of highly-trained, competent personnel.

Q. In other words, you can't say you're streamlining the Navy, like the Army is, because of these new weapons; that won't apply to the Navy?

A. It certainly will apply in the sense that you have fewer numbers of ships . . . That's logical, if the fire power of one ship is equivalent to the fire power of a hundred ships that we had in World War II—well, there are chances that we have fewer ships. The same is true of aircraft. The same might very well be true in numbers of missile launchers compared with 15-inch rifles and so on . . . but the dollar is another story. My guess is the dollar curve goes up.

Q. I'd like to throw in a final question, if I may . . . about the Russian submarine threat. Supposedly, they have 400 submarines and supposedly they have been building missiles for their submarines. Do you feel that the Russian submarine fleet is as great a threat as has been indicated in the press lately?

A. I don't think you can exaggerate the threat. The number of Russian submarines is somewhere between 500 and 600. They are producing submarines at the rate of two new ones every three weeks. They are concentrating, for the most part, as far as we know, on the so-called W-class submarines which are the long-range submarines capable of operating in the Western Atlantic, for example. We have no reason to think that the Russians are not also working hard on nuclear propelled submarines and missile launching submarines. We feel that the Russian submarine threat to the United States, as I say, cannot be exaggerated.

Q. Do you think that the Russians are ahead of us in missile launching submarine development?

A. We'd like to know much more about the Russian submarine fleet than we do, along with the rest of the Russian military effort. Personally, based on what I have heard, I'm inclined to think that we are ahead of the Russians in submarine construction and in missile launching capability in submarines.✶

Need for Space Flight Know-how

Vital Unknowns of Flight Beyond the Atmosphere Can Only Come from New Research Methods

By Cdr. George W. Hoover, USN

Behind the production of ships and planes and weapons is a vast research and development program. Paralleling this type of research is an almost equally large program to keep the fighting men alive, not only in the face of enemy weapons, but against the adverse effects of nature as well.

These adverse effects are some of nature's stumbling blocks placed in the path of man's progress, such as his conquest of high speed, high altitude flight. The results of this type of research are not only advantageous to military knowledge, but are equally effective in the advancement of civil aviation. This is particularly true now with the advent of jet transport aircraft, and will be even more so as aircraft begin to fly beyond the atmosphere.

Out of these research programs have come many test aircraft, each a little faster than its predecessor and each capable of reaching a higher altitude.

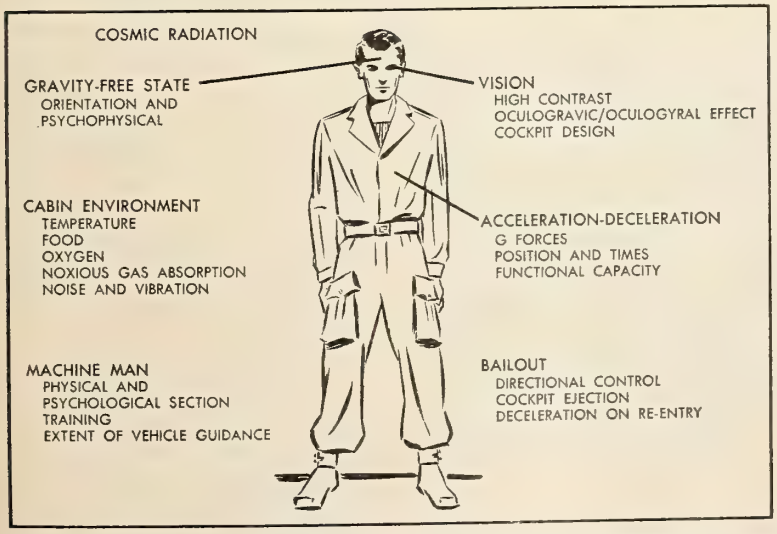
In August 1947, the Douglas Skystreak set two records at Muroc, California; the first 640.7 mph and the second five days later, 650.6 mph. December of 1947 brought forth the Bell X-1 which set several records in excess of the speed of sound.

Douglas came back in August of 1951 with the Skyrocket, D558-II, which established a speed of 1238 mph and an altitude of 79,000 feet. In August of 1953 this record was exceeded by the same Skyrocket which reached an altitude of 83,235 feet and in November 1953 a new speed record of 1327 mph was made.

The Bell X-1A followed the Douglas flights by setting a record of 1650 mph in December 1953. The X-2, the successor of the X-1A crashed in September 1956, but not before setting records of over 2100 mph and an altitude of 126,000 feet. Recently the announcement was made of a new research aircraft which will be capable of even higher speeds and altitudes.

As you can see from the record, man is definitely outward bound—but not before some means is developed to give us the vital answers to the multitude of unknowns required to make manned space flight possible.

Technological advances in power plants and in aerodynamics have indicated that aircraft capable of carrying men completely beyond the earth's protective atmosphere are not only feasible but probable within a very short time. One feasibility study, made to determine the possibility of an aircraft capable of such performance, indicated that altitudes in excess of 500,000 feet were possible with speeds approaching 4,000 mph. Such an aircraft could be used to study methods of re-entering the atmosphere, study insulating coatings, provide experience in space flight, and stimulate development of better rocket engines.



Many Problems, Little Data

Further studies have indicated that not only are there many problems, but that very little data is available in many of the critical areas.

As an example, in the field of Geophysics and Astrophysics the problems of protecting man and his machine are relatively unanswered. Solar radiation will affect the structures and materials, the instrumentation, and the man himself. Cosmic radiation effects must be neutralized. Meteroids will cause damage to the machine by surface effect or direct collision. The chemical state of the atmosphere will affect structures, radio communications, aerodynamics, and will create problems due to the accumulation of charge on the machine. Winds and turbulence will raise problems in the guidance and the stability of the craft.

Each of these problems must be studied by actually measuring the effects in order to determine methods of preventing damage to both the machine and the occupant.

In the field of Aeromedicine similar problems must be studied. There are problems of living in a gravity-free state effecting orientation and those of the psychophysical condition of the man. Cabin environment must be studied in order to be able to maintain proper temperature, oxygen supply, noxious gas absorption, noise and vibration, and sufficient food for the crew. There must be

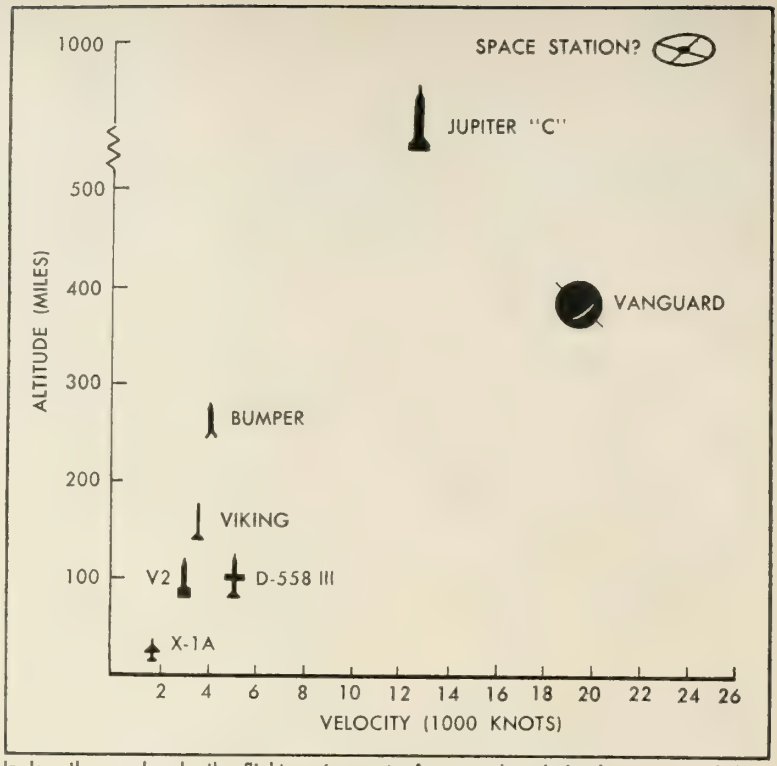
Some of the new environmental conditions to which man will have to adapt himself or from which he will need protection in space.

provision for control during emergencies, escape from damaged vehicles, and safe deceleration on re-entry.

G-force position and time, as well as total capacity must be studied to answer the problems of acceleration and deceleration. Effect on vision due to high contrast, gravity and gyroscopic action must be understood in order for man to operate efficiently. The man-machine system must be studied to determine the physical and psychological requirements, the training requirements, and the extent of required control.

Here again in this field a means must be developed to obtain the information necessary to make man's existence in space possible. And not only in this field, but in Guidance and Control, Communications, Propulsion, Auxiliary Power, Structures and Materials, Aerodynamics, Re-entry, and Launching and Landing. In all of these fields, many tests and evaluations must be made before sufficient knowledge will be obtained to try manned flight into space.

As a matter of fact, present studies indicate that in the field of Guidance and Control, we know about 40 per cent of what we should know in order to send a manned ship into space. In Communication we know about 60 per cent of what we need. In Aeromedicine we have less than 10 per cent of the required knowledge and in Launching and Landing we know practically nothing. In other areas we are about as badly informed. This is not because we are not looking for answers, but because there has been no way to obtain the required knowledge.



New Research Tools Needed

Present methods of gathering research data are inadequate. Ordinary aircraft cannot fly high enough to measure the environment in which these aircraft of tomorrow will operate. Rocket powered test aircraft, although having the capability of achieving extremely high altitudes and speeds, can only gather data for seconds of time. This is due to the short duration powered flight.

Even high altitude rockets, capable of attaining extremely high altitudes can only provide minutes of data gathering, and then only for a few answers at a time. With the number of answers required, this becomes a rather expensive method of obtaining the necessary information. High altitude balloons, although capable of remaining aloft for hours at a time, can only reach the top fringes of the atmosphere, beyond which lies most of the unknowns.

In other words a means must be utilized which will give long periods of measurement time at extremely high altitudes at very high speeds.

New research tools must be developed which meet these requirements, and these research tools will be satellites.

In less than a decade the flight environment of man-made vehicles has progressed from subsonic and under 100,000 feet to Mach 19 and over 650 miles up.

Not just one, but a long series of satellites, each gathering more and more information, until all the answers are obtained. Actually the satellite is not an outgrowth of Science Fiction, but is just a logical step in a very normal research program, the results of which will be beneficial not only to our nation, but to the entire world. A satellite is the only space research tool capable of being developed at this time to permit man to learn more about himself, the world, and the planetary system in which he lives.

In addition to the basic scientific data which will be gained from the early satellites, more and more instrumentation will be included as the satellites are enlarged, and information will be gathered in order that man can learn how to penetrate space and return safely.

Studies of the launching techniques of the satellite missiles will give us necessary information as to the acceleration forces to which man will be subjected in his take-off from the earth.

The trajectories and paths of the satellites as they enter their orbits will tell us much about the control which will be necessary in order to place a manned ship in its orbit. Much will be learned about the problem of placing two vehicles in the same orbit, for rendezvous in space will be considerably different than in the atmosphere. In addition to these data, information can be obtained to determine the man's share in operating the equipment and the amount of full automation required.

Launching a series of satellites will tell us what we need to know about power requirements, not only for propulsion, but internal power as well.

The relay of information will test existing communication techniques as well as define the requirements for new methods. The use of digital techniques, data links, television, and methods of relay are only some of the many experiments which can be carried out.

Medical experiments will undoubtedly be of top interest in the early satellites. The effects on human beings can be extrapolated from telemetered data as well as from the recovery of animal subjects. Almost every part of the satellite and launching vehicle can be used in the aeromedical aspects of space flight. Later satellites will be returned to earth through the use of retro-rockets, drag techniques and parachute devices. These will give us the answers to the re-entry problems and the return and landing.

Man will fly into space just as the Wright brothers flew the first aircraft. The satellite will show us the way—first unmanned, then manned, and finally orbiting observatories and space stations.

[*Opinions expressed in this article are those of the author and are not to be construed as official or as reflecting the views of the Navy Dept.*]

IAF AND UNESCO

Formal recognition of the International Astronautical Federation as a consultative Non-Governmental Organization (NGO) of the United Nations Educational, Scientific and Cultural Organization (UNESCO) now seems virtually assured.

A two year delay in final action, however, appears to be unavoidable. Progress to date is due mainly to the efforts of Andrew G. Haley, General Council and a Director of the American Rocket Society and Chairman of the International Affairs Committee of the IAF.

Once space travel becomes a common thing, almost from the first of manned space flight in fact, a number of thorny international legal problems are bound to arise.

These include flight over sovereign territory—how high is up—problems of radio channel allocation throughout a wide range of frequencies; satellite navigational control; weather monitoring, etc.

It is obviously desirable that the machinery for sorting out these problems be in existence before they occur, rather than have to be jerry-rigged afterwards. It also seems desirable to set up this machinery in already-recognized, established international bodies.

For this reason, there has been a considerable effort during the past few years to link up the IAF with the UNESCO. Recently considerable progress has been made.

Elected at last September's Rome meeting of the IAF as that organization's official delegate to the 9th General Conference of UNESCO in New Delhi, Mr. Haley spent two weeks last November in India pushing for consultative status for the IAF.

IAF feels that with manned space flight now assured in the proximate future a proper grounding now for UNESCO will prevent a lot of headaches later. Mr. Haley's reputation is as one of the country's foremost authorities in the growing field of space law.

UNESCO Status Voted IAF

In New Delhi, NGO cooperating status for the IAF was motioned by Prof. Shemuel Sambursky, delegate from Israel and personal friend of Mr. Haley and Dr. Theodore von Karman. About a dozen organizations were proposed for membership in this category. All were approved in one vote by a small margin.

Mr. Haley reports that one of the biggest stumbling blocks has been UNESCO's inability so far to agree on the conditions of NGO status. It was for this reason that on the day following the vote for admission, this action was revoked. Mr. Haley, having departed India on the evening of the first vote, Prof. Sambursky carried on the fight. In a letter, he writes:

"In spite of this reversal, I took the question up in the program commission under the chapter, Cooperation with International Organizations of the Natural Science Department. I formally moved that UNESCO's Secretariat study the possibility of cooperation with the IAF, especially of consultation between UNESCO experts and the scientific committee of the IAF on all the problems of space flight and astronautics. Prof. Pierre Auger (Assistant UNESCO Director) was asked by the Chairman what his attitude was, and he replied in the affirmative, whereafter the matter was passed without opposition."

Preliminary negotiations are now under way for working out areas of cooperation between IAF and UNESCO. The former has agreed to bear the costs of these early studies, if necessary. It seems that by the expiration of the two year delay now required for any new admissions, most of the groundwork will have been completed.

In this connection Mr. Haley says: "The inauguration of the program in a peace and uncomplicated manner is a great achievement of scientists throughout the world."

On his way back to the United States, Mr. Haley stopped off in Athens, and there gave a lecture on the current problems of astronautics and showed movies of developments as the dinner guest of King Paul and Queen Fredericka of Greece.

The Queen, Mr. Haley reports, shows great interest in the field, along with her brother, Welf Heinrich, Prince of Hanover. The latter, like Mr. Haley, is an accomplished authority on space law. Other guests at the dinner included the Chiefs of Staff of the Greek Armed Service, the Minister of Defense, U.S. Ambassador George Allen and other embassy officials.

Films Draw 700

One showing of these films in Paris drew an audience of more than 700 people which, Mr. Haley suggests, is a good measure of the growing interest throughout the world in the field of astronautics.

The ARS director's films are currently being shown in other cities throughout France under the auspices of the French Astronautical Society, whose President, General P. Bergeron, plans to visit the U.S. during the latter part of January.

Internationalist Andrew G. Haley and Soviet space man Leonide Sedov at last September's Rome meeting of the International Astronautical Federation.

RICHMOND PUBLIC LIBRARY

EDUCATION . . .

. . . for the Missile Age

How different the criteria?

How different the curriculum?

By Kurt R. Stehling
Head of Propulsion,
Project Vanguard
Naval Research Laboratory

IT IS OBVIOUS that education begins in the primary grades. It is perhaps not so obvious that the inspiration of the teachers and the quality of the subject matter taught in these early years are the mainsprings for the responsiveness and interest of a young person in the very important later high school and university years.

There is presently a great furor in this country about the lack of teachers, school physical plant, and money to pay the one or build the other. We have the paradox of a society composed of taxpayers who piously wish for these elements of education, but who are not willing to pay. Instead, they pour billions of dollars each year into vast amounts of "necessary" commodities, such as liquor and automobiles.

Educators and teachers are faced with the prospect of bringing up and educating the maladjusted offspring of those taxpayers who, in most cases, should be doing at home much of the upbringing left to the schools.

The great missile age is about to descend upon us. This will demand a generation of young people trained in the fundamentals of science and ancillary subjects. These very subjects are often bypassed in the frantic scramble to process every pupil as fast as possible through the school mill.

All this is enthusiastically endorsed by the parents who do not wish to see their progeny burdened with any intellectual exercises. Universities, especially those in the upper ranks of scholarship, often have difficulty in adapting their students to the rigorous curriculum which these good universities demand.

Those students who wish to enter the field of guided missile technology must be prepared to have a good grounding in physics, chemistry, and mathematics. They should not have their thought processes cluttered with too many generalities—liberally spread on by technical colleges who believe a student's education is directly proportional to the total number of technical subjects he has studied.

Industry Must Share Burden

However, it must also be said that industry, particularly the guided missile industry, must share the burden of inspiring and training young people for this very complicated business. So far, industry has played only a meager part in this scheme, although many industrialists are the first to scream about the lack of engineers and physicists.

Yet, the aircraft, missile and component industry is partly responsible for this shortage of scientific workers:

1—Industry lets the schools do all the educating without much "on-the-job" training. The supervisory and managerial personnel, often haphazardly and sloppily trained in their functions, are busy empire building. They cannot, even if they wished, take a young person and lead him through the jungle of paper work complexities which cover the average engineering department.

2—Cost-plus contracts and empire building seem to favor the sucking in of "bodies" (a cynical generic term now widely used) without fitting these "bodies" into a proper niche and making the best use of them. Therefore, we often have three people doing the job of one. Meantime several other extras must undo the miasma of wasted effort introduced by this last useless group.

3—The same situation has the further effect of permitting industry to raid the staff of the very universities which supply the graduates industry needs so badly. The attitude is "Let's hire a few PhD.'s to build up our personnel roster on contract proposals." Many of the universities, therefore, have difficulty in maintaining their staffs, especially with the better people who have made names for themselves through publication and research. Those men who have been seduced from their campus positions by the lure of greatly increased salaries are often thrown into the wilderness of industrial operations without being especially fitted for this atmosphere.

Conflict Tough To Solve

There is nothing wrong with the premise that our technical colleges and universities should serve industry and the community at large. And they must maintain their contacts with industry if they are to sustain a fresh viewpoint.

What is wrong, however, is the hiring of these research workers and scholars on a full-time basis, thus killing the goose that lays the golden egg. Again, this would not be so bad if these teachers found themselves in an amendable environment; but since many are first and foremost teachers, their best talents are not compatible with the fast-moving requirements of industry.

What then is the answer? Should the universities try to raise salaries to industrial levels? Should they permit more outside consultation by the faculty? Or should they encourage industry to build research centers on the campus to enable the faculty to work in two places at once?

In the case of the first question, it must be obvious that most universities in U.S. have neither the endowment nor

wherewithal to pay industrial salaries. A few of the wealthier institutions could, perhaps, approach this by reducing the faculty and accepting more government or industry-sponsored research, and an increment above academic salaries.

Indeed, many technical institutions are so loaded down by outside contracts, usually government, that the scientific faculty in its eagerness to make a little more money spends as much time working on these sponsored contracts as on teaching. Yet teaching should surely be the prime objective of a university. Incidentally, a very undesirable by-product of research is the inequity which is produced in faculty salaries in an arts and science institution. After all, the professor of ancient history, arts, English, philosophy, etc., can hardly expect a research contract which will increase his regular salary, although an altruistic government agency will sometimes hand out such a small research contract.

Of course, the arts faculty ought to live with the ugly realization that it has no industrial salary scale to live up to since industry is not yet in the habit of hiring historians, philosophers, and students of English, although it ought to begin to do so.

The second question asked was "Should the faculty be allowed extra consulting time to implement their salaries?" This, of course, is widely done at present and is perhaps the least painful way to aid the industry and u n i v e r s i t y through the feedback so obtained. However, the amount of consulting can easily become excessive and too often transcends into a full time job in industry.

The last question, i.e., whether universities should permit the building of engineering research laboratories on the campus, can be answered by pointing out that this is presently happening at such institutions as Massachusetts Institute of Technology, University of California and University of Chicago. There is no question that the campus atmosphere attracts many missile engineers who think fondly of their college days and often tire of industry's pace.

Several missile firms, such as Lockheed, have taken advantage of this recognized feeling by moving research labs close to a university campus. At the same time they have the advantage of the proximity of a scientific institution with all its resources of faculty, laboratories, and libraries.

Missile Age Demands a New Man

The missile age will demand a new man. He must be educated not only in the superficialities of college curriculae, but he must be grounded in the fundamentals of physics and other branches of science and mathematics.

We tend to produce today an overtrained engineer who is only partly educated. The ability to write a clear and concise report, the ability to reach the fundamentals of a problem without a great crowd of redundant material is an important one. The growth towards specialization is becoming an obsession.

Many young engineers, and old ones too, are afraid to express themselves in a field other than their own narrow one. There is open jealous compartmentalization of the various enterprises on missile projects. The top missile engineer should be encouraged to cut across party lines and make contributions where he can—whether it be propulsion, guidance and control, structures, electrical and telemetering or dynamics.

Some of these fields, such as solid-state physics, metallurgy and cryogenics, are often neglected or underpopulated—both at the university level and beyond—because many students take the easier and more glamorous courses. Yet metallurgy, for example, is becoming a crucial factor in this age of super-jet engines and high pressure rocket engines and gas turbines.

Another interesting area with great potential is that of ceramics. Only two or three universities in this country have the study of ceramics as an undergraduate and graduate specialty. The missile age will demand trained and experienced men in such areas as ceramic rocket thrust chamber design, aerodynamic-heat resistant coating, "cermets" and ceramic coated turbine blades, acid resistant coatings, etc.

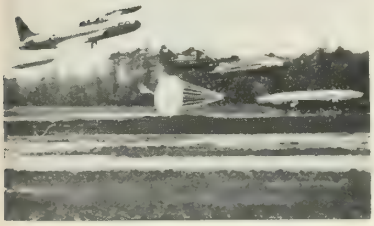
If a typical missile is divided into its major domains it is possible to point to either a major course of study required or to the kind of engineer who is doing such work or who should be.

It is not yet apparent whether the complete missile engineer of the future will be a finished product of some missile engineering curriculum or whether he will, as at present, "grow" into the job. Although some universities have missile engineering courses as part of an aeronautics curriculum, industry is presently fitting non-aeronautical engineers into many positions which may some day be filled only by recognized missile engineers.

The missile engineer of the future will need a thorough grounding in only the fundamentals of physics, mathematics and chemistry. He must have a sense of dedication and enthusiasm and an awareness of the mighty potential of missile technology—space flight. Then will he be an astronautical engineer. ✶

[*Opinions expressed in this article are those of the author and are not to be construed as official or as reflecting the views of the Navy Dept.*]

Seventeen-year-old rocketeer Jimmy Blackmon receives advice on propellant flow from some of the nation's top rocket engineers at the American Rocket Society annual meeting. Jimmy had just received the $1,000 Chrysler Corp. award for his basement-built rocket. "Now I can go to college," he said. Chrysler is to be congratulated for instituting this annual award, for if the shortage of engineers is critical in aviation, it's catastrophic in the missile industry.



Versatile Regulus Now Operational

Factory checked, canned Chance-Vought Regulus leaves Dallas for parts unknown.

A big bird and quite conventional, this atomic missile is ready for war today.

Drag chute flares as chase planes guide test/training Regulus to safe landing.

At first glance, the Chance-Vought *Regulus* is a very ordinary unsensational missile. It's a nine year old program. So it's not new. It's an air-breather; is subsonic; and has a range of well under 1,000 miles. But there its plainness ends.

This undramatic approach to the very dramatic postwar business of guided missiles is paying dividends with interest compounded. For example:

—It is fully operational, can deliver an atomic warhead over 500 miles away under any weather conditions.

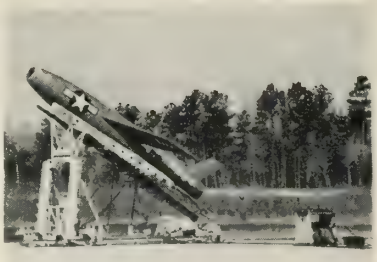
—It works as well on land, surface ship or submarine.

—There are even unconfirmed reports that it has been tried as an air-to-surface missile in tests from a B-52.

—In the fleet the on target success probability of each launch is 0.91, which must be some kind of record for a medium range missile.

—Guided Missile Group II at Chincoteague, Va., has completed over 100 launchings since it was formed in September, 1955.

—And in most of these cases the bird flew home and landed to be studied and used again, because training and testing versions carry retractable wheels instead of an explosive payload. This compares, for example, to the $70,000 that's splashed every time a *Matador* is launched.



—Initially guided by a chase plane, *Regulus* can now also be ground directed to its target and will soon be equipped with self-homing equipment.

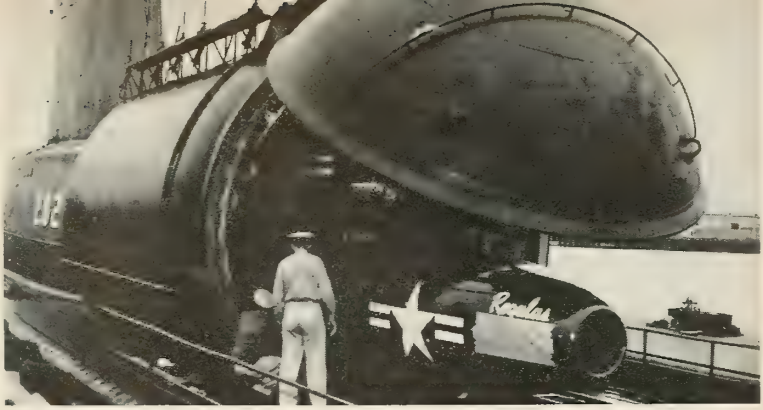
That's *Regulus I*, the Navy's fully operational medium-range surface-to-surface missile.

Now *Regulus II* is flying (see page 42 for artist's conception). Soon

Below—Wings tucked in, Regulus reports aboard submarine to make lethal team.

The Marine Corps should be happy that Navy's over 500-mile missile . . .

. . . works as well on land as it does at sea as this picture series of a . . .



. . . JATO take-off at Navy's Chincoteague missile center show. Also . . .

. . . Regulus now needs no chase plane but can be ground guided from these trailers.

Like its manned cousins, this versatile bird doesn't need JATO . . .

One bird slides easily from twin cacoon on submarine's deck while second missile waits for it to clear before rolling down and around to the ready.

. . . to take off on its mission from any of the Navy's aircraft carriers but . . .

. . . uses conventional steam catapulting gear plus inexpensive disposable dolly . . .

. . . that splashes off carrier's bow as airborne Regulus streaks off to target.

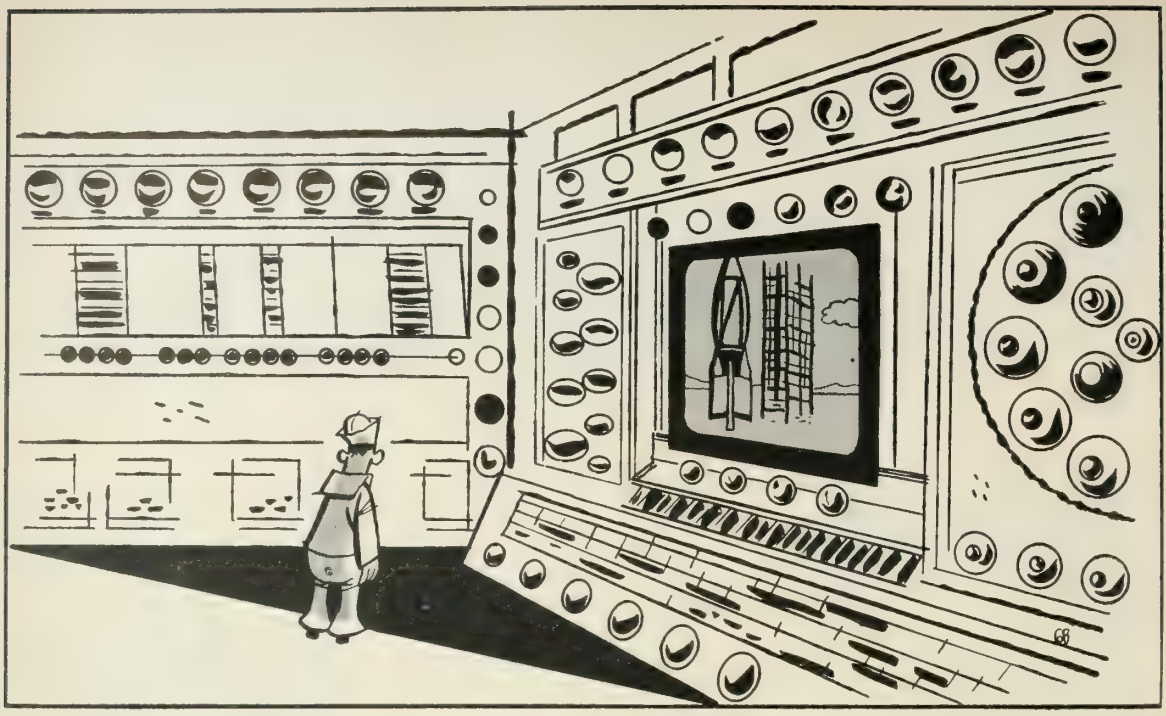
to be operational, this improvement is supersonic and has greater range. It will require only slight modification to fit current *Regulus I* (submarine equipment and like its older brother, its got wheels for training and testing.

The secret of success of the *Regulus* program makes very interesting reading. Being a relatively simple conception in its original form, more time was available in the beginning to develop an operational missile system. Less had to be spent chasing down some of the more exotic bugs that infest our hypersonic and ballistic efforts. Once the system itself was perfected, improvements came naturally.

In all its life, *Regulus* has flown fewer than 300 hours, but they were hours well spent. For if something went wrong with a flight, in most cases is was possible to direct the missile back to base for a wheels-down landing. Then the recalcitrant circuit, the twisted mechanical linkage or the overheated tube could be chased down and studied in detail. How many Northrop and Air Force engineers would rather have a whole bird in the hand than a twisted wreck in the Brazilian bush?

Not only did this advantage of being able to recover the missile intact enable early perfection, but it also expedited improvements for the same reason. What's more, of course, it saved the American taxpayer a lot of hard-earned dollars.

The Navy figures that even if the current *Regulus* amounts to little more than a highly successful unmanned Kamakazi, it has gained a good sound reliable missile system on which it can build effective future generations. For after the *Regulus II* will come the *Triton*—a "zip" fueled, ramjet powered bird with a 1500 mile range at speeds approaching Mach 4.0, a natural outgrowth of 100 per cent complete *Regulus* knowhow ✶



Cacoon door closed, Regulus is quickly mounted, elevated and ready to fire . . .

. . . and as JATO smoke and fire obscures conning tower, the Navy's pride . . .

. . . is airborne, the submarine having been on the surface for only a few minutes.

Too Many Pushbuttons

By Donald E. Mullen
Missile and Ordnance Systems Department,
General Electric Company

THE NAVY CHIEF entered the block house at the White Sands Proving Ground, New Mexico, to witness his first guided missile firing. Four hours and two aborted launching attempts later, he summarized his views —"I know why you can't make it work; too many pushbuttons!"

It was an obvious remark to make, but its true implication is of vital importance to the nation's defensive strength. In fact, the remark can be used as a very serviceable definition of the greatest remaining problem in the development of practical missile weapons—usability. Unless these complex weapons are simplified and made reliable, our arsenal will be stocked with impressive but useless machinery, totally beyond the comprehension of our men in the service.

To this end, industry and all the procuring services are placing top priorities on reliability, simplicity, safety and similar practical characteristics for guided missiles. While there is no pat answer to the problem of achieving reliability and simplicity in guided missiles, there are giant steps in philosophy that approach this goal.

Before defining these steps, the goal must be defined in meaningful terms. For instance, if a Task Force Commander is about to launch a close support missile over his own ships, how safe should he insist that it be? If he demanded that no more than one missile in 5000 would fail disastrously, this would not be unreasonable. Translate that kind of reliability to an automobile. Taking one trip a day, we could then expect almost fourteen years of untroubled driving.

Understanding the need for this kind of reliability is simple. Achieving it in the battle area is something else again! The classical methods fall into four categories.

Redundancy is one of these, but two of everything adds weight, cost and complexity. It means that a missile soon gets uneconomical, unwieldy and beyond the ability of a sailor to cope with the maintenance and operation of its complex circuitry. In some cases, however, this is the only practical way out.

The second approach is through "fail-safe" design. Reliability, as such, is not considered to be all important here. If a component fails, it does so in a manner designed to prevent catastrophic failure of the weapon system. Again, this is not the best answer, since it could result in substantial numbers of "duds"—as safe for the enemy as for our own troops. But in many instances, it is the only answer.

The most direct, and hardest approach to reliability is to simplify: simplification holds the greatest promise for the future of truly practical missile weapon systems. The fewer the parts, the fewer potential failures, and the fewer the parts, the easier the system is to cope with. The means for the creation of reliability, simplicity will become the guide lines for all missile men. There are any number of reasons why it is extremely difficult to simplify, but it is an old saying that the most worthy accomplishments entail the hardest work.

First problems of simplification are the limitations in the "state of the art."

In essence, this means that no one knows how to do it and/or no one has ever done it before. Assume, for example, that the problem at hand is to design an extremely accurate guidance system for the intercontinental missile. The first demonstration of feasibility in the laboratory might be the wildest dream of the scientist. He cannot and must not be bothered by the fact that his first breadboard circuit in the laboratory may not be simple or reliable. And no manager in his right mind would attempt to force such considerations on a truly creative mind. Developing increased simplicity and reliability in such a device is, in fact, another break-through in the state of the art.

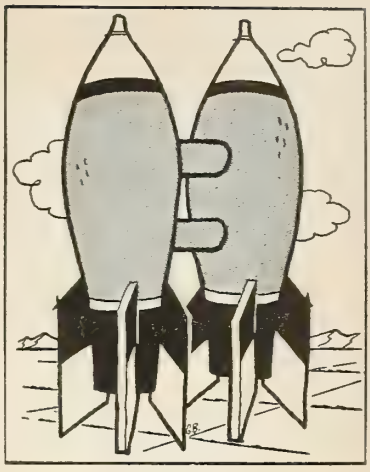
Industry's answer here is to apply the ingredients of time, money and specialized talent to the simplification problem. The talent in this case, however, cannot be of the same type as the creative scientist. The simplification engineer must be dedicated to the reworking of others' creations so that the design will be compatible with the conditions of their ultimate use. Right now, these men are a rather rare breed, somewhat like operations research men and hypersonic aerophysicists. But as the need increases, the breed increases, yielding to the old law of supply and demand. It has been General Electric's experience that when we can't find them we have to make them.

The military service too has an obligation in the solution of this problem. It must conscientiously and regularly reappraise the military characteristics of each weapon in the light of the developer's progress and other new facts that have become known. It is also important that the Services differentiate between what would be nice to have and what they must have.

A typical example here might be the classic conflict of accuracy versus simplicity. The Army, for instance, has specified that a certain guided missile must be just so accurate. Should the nuclear efficiency of the warhead later be improved to yield a greater destructive force, it may mean that a relaxation of the missile accuracy requirement is possible.

Simplified Assembly and Testing

Achieving simplicity in the original design is obviously the brute force method. Because it is a direct approach, it will undoubtedly be the most fruitful over the years. In the meantime, there are other constructive methods which can be employed to ease the problem.



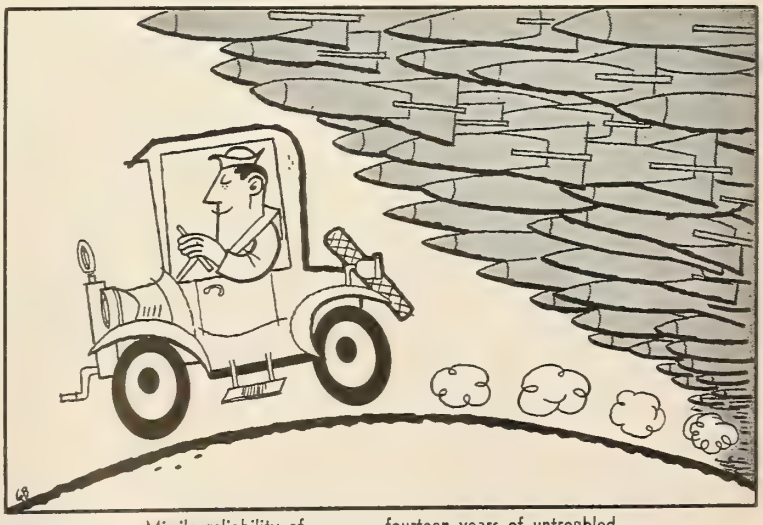
One such approach to the problem of simplicity is the *employment of advanced packaging and modular techniques*. In missiles, the added cost of this kind of assembly is not prohibitive. The initial design and manufacturing cost of any given part of a guided missile is completely lost in the cost of transporting, storing, maintaining and firing the weapon in the battle field. Further, the cost of the missile's atomic warhead is tremendous.

Add to these the true cost of a failure of a guided missile at a critical time in a battle, and it is quite apparent that it is truly economical to employ the most advanced and expensive modular techniques possible in the design of current missile weapons.

Very closely allied to the employment of advanced packaging techniques is the development of proper field test and maintenance equipment. The need, as always, is obvious, like the case of such important field equipment as a beer can opener at a picnic. In many ways, it is possible to substitute calibrated equipment for calibrated men. In military terms, this means that the average GI or sailor with the proper equipment can do the job of checking out a guided missile and then specifying the required maintenance.

All attempts to indoctrinate military personnel in the complexities of development-type testing procedures ended in abject failure. Weapons that were supposed to be in "hit and run" warfare suddenly required days instead of hours to set up, and still did not demonstrate a shred of the reliability that was originally required of them.

Getting the scientist responsible for missile development to stand still long enough to consider the testing problem is the toughest part of this approach. Second hardest is the convincing of the procuring service that high and early expenditures together with minor delays in the missile program are truly necessary to surround the field equipment problem. But in each instance of proper attention to test equipment, the post mortem analysis more than justifies the effort.



Redundancy...

When the latest in packaging techniques is coupled with truly tactical field test equipment, the problem of detecting and correcting malfunction in even the most complex equipment becomes a matter of observing either a red or a green light, followed by the replacement of a modular unit.

This utopian condition, however, is not particularly easy to achieve. First, a test method must be devised which is valid, sufficiently accurate, and repeatable. Further, the test equipment must be designed to standards similar to or even more exacting than those imposed on the guided missile. Lastly the tester shall be simple, reliable, easy to operate, and self-calibrating.

There can be no such things as

Missile reliability of 4999 out of 5000 = fourteen years of untroubled driving in the family car.

Fail-safe design . . .

testers to test the tester. It is significant, however, that tremendous advances have been made in the art of testing. Entire missile systems can now be tested remotely and automatically throughout a simulated flight procedure. The resultant go or no-go indication is then sufficient information for the operator to press the firing button or to call the maintenance man. Since the feasibility of this type of testing equipment has been demonstrated, it now remains for the military services to insist on test equipment considerations from their contractors from the outset of research and development on a missile weapon.

"Horse Sense" Helps Too

In all the approaches thus far, the answer has appeared to be the result of time, money and manpower. There is another which required none of these.

Early in one missile program, for example, engineers were confronted with the need for a positive and reliable device to indicate that combustion had occurred in the rocket motor. The laboratory was soon filled with breadboards using thermocouples, pressure sensors and photo electric devices in various complex circuits.

One man looked at the problem a little differently. He advised the use of a piece of wood with a bare wire stapled to it. If this assembly were placed at the exit of the rocket motor, he was sure it would disintegrate when the motor was burning properly.

This device, called the "burp board," is now several years old and still in use. It represents the type of analysis that results in the simplest possible method to perform the required function. This is the type of thinking which can produce more practical weapons immediately. Like all the other solutions, however, it does have its drawbacks.

Engineers can be directed to be ingenious, but it's rather difficult to enforce this directive. As one engineer said when asked to use horse sense—"I didn't take that course at college."

Possibly the only other important simplification area remaining is best illustrated by the case of the old farmer who refused to buy a book on the scientific farming method because he "already knew twice as much about scientific farming as his actual procedures reflected." In other words, a lot can be gained just by making better use of current knowhow.

After the system has been designed, considering redundancy, fail-safe design, and simplification, there is yet another step to take—reevaluation. First, see that the system is properly balanced. No component should be unduly strong or weak. In the past, complex equipment has suffered from this ailment of unbalance. In World War II radar sets, for example, less than ten per cent of the components caused more than half of the failures.

The problem of balance also shows up in priorities or favors granted to engineers working on different parts of the missile. A structures man decides he needs an additional bulkhead for strength. It passes through an area previously reserved for the electronic guidance. The proper answer to the question, "Who gives?", must necessarily be the subject of a study in system balance.

Also a part of evaluation is the second look at the validity of the developed system as an answer to the military problem. Questions of weight, size and pay load can be satisfied by inspection. Where the reevaluation becomes complex is in the area of strength of materials and the true nature of the stresses caused by the environment all the way from the factory to the target. No matter how diligently a design has been pursued, if we don't know what it must withstand, we don't know that it will survive.

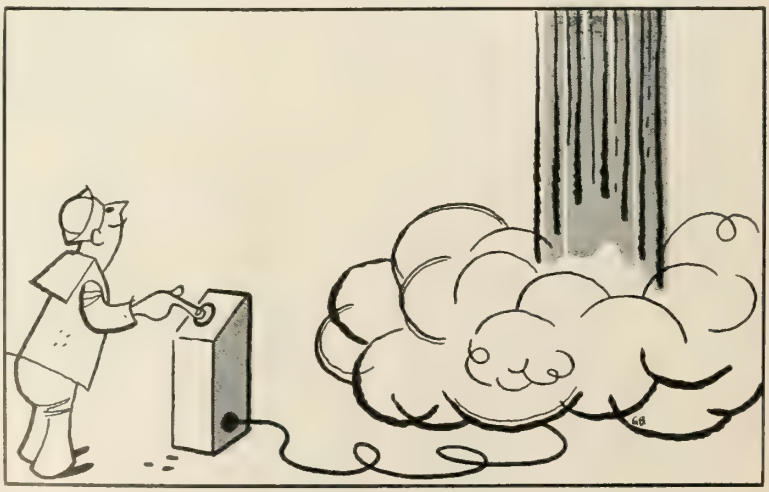
Seven Points of Reliability

Using all these suggestions, a very worthwhile approach to the development of a guided missile weapon can be synthesized:

1—Military specifications—the system performance requirements—must be written so as to provide the maximum possibility of ending up with a truly practical weapon;

2—Specifications must be reevaluated and changed continuously, taking care that such changes will not destroy the continuity and effectiveness of the development program.

3—Industry must plan and man its projects so that proper attention is given to designing for simplicity.



4—Principles of redundancy and fail-safe design must be included when necessary to assure appropriate reliability and safety.

5—Advanced packaging techniques, including modular design should be coupled with the latest in field test equipment to assure maintainability and constant weapon readiness.

6—True functional analysis should be applied to assure that the simplest possible method for performing the given function will be employed.

7—And in all the above things, both industry and the military should use their utmost capabilities in the creation of a practical missile.

If all these things are done, the guided missile system of the future will be worthy of all efforts and the dependence placed on it as the backbone of this nation's arsenal ★

Simplification . . .

Simulators in Navy Missile Training

By LCDR John Huson, USNR, and Chief Keith K. Smell, TDC, USN

BECAUSE OF the lethal qualities of guided missiles they should and can be entrusted only to the care of highly skilled military personnel. Reasons for this high degree of skill and the means for obtaining it involve complex scientific and educational problems.

The rapidity with which the military research and development program is moving, particularly in guided missiles, demands new and more effective methods of training men in highly complex skills. In the beginning, technical military training followed the pattern of the guild system. Ships were built by craftsmen assisted by apprentices and laborers. Design of equipment was headed by the oldest member of a shipwright house and carried out by lesser members of the companies.

Use of equipment was taught by on-the-job methods; this was effective but slow and sometimes quite dangerous. Special groups would be trained and these men in turn would train other individuals. Even the most simple equipment was painstakingly taught in order to insure proper use.

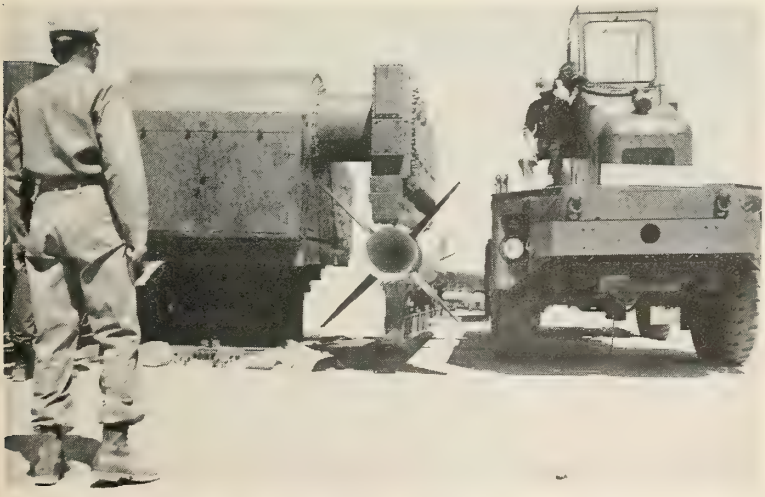
No great strides were made in the field of military training until a dual crisis arose in World War II. The problem of training men in an incredibly short time with scarce and expensive operational equipment required immediate solving. A more subtle problem arose from the fact that research efforts were creating new knowledges and weapons faster than men could be trained to use them effectively. Steps had to be taken which would train men in larger numbers, faster, safer, and at a lower cost.

Today, much the same is true in the missile field. The dynamic progress of research and development necessitates accelerated training programs for military personnel who must operate and maintain the new equipment.

Yet the sources for obtaining necessary information are too widespread and diversified; there are no missile engineers graduating from colleges; and the weapon system team concept has not yet been fully enough developed.

In spite of these difficulties, men must be trained more thoroughly in a wider variety of skills than at any previous time in our military history. In the first place, the guided missile is a complex piece of equipment with equally complex testing and computer equipments. All of these must be maintained and operated intelligently within sharply defined time and accuracy limits. The margin for error is further reduced because once launched, the guided missile cannot be retrieved. It is too costly to permit trial and error launchings.

The variety and complexity of skills to be learned by guided missile personnel within pressing time limits, present a formidable training problem. But it can be substantially reduced by the use of properly designed and properly utilized training devices.



Such devices have proven their worth in many fields of military training. The use of a bomber flight trainer, for example, has been credited with saving the U.S. Air Force 119 lives and $28,850,000 in a period of one year. The Navy estimates the cost of training men in operational aircraft to be $560 per hour, as against $66 for equivalent training in a flight simulator which never leaves the ground.

The time required for training with simulators and other synthetic equipment is shortened because they can be operated day and night without regard for weather or other conditions which would affect the availability of the operational equipment. Synthetic training devices have been and are being developed for all the armed forces and for all aspects of modern warfare, whether it is airborne, surface, or sub-surface in nature. Over $135,000,000 worth of training devices are now used by the services.

In the guided missile field training devices have the following advantages:

1—Saving lives in hazardous situations.

2—Saving operational equipment for tactical use.

Navy's Training Device Center missile simulator package includes a complete store of spare parts for replacement when trainees make a mistake. Shown is the Marine Corp's mobile TERRIER launcher.

3—Increasing the number of students that can be trained.

4—Permitting accurate scoring of the student.

5—Enabling training to be stopped at any point for instructor guidance.

6—Enabling training to be carried on independent of weather conditions or availability of operational equipment.

7—Enabling round-the-clock 24 hour training to be conducted.

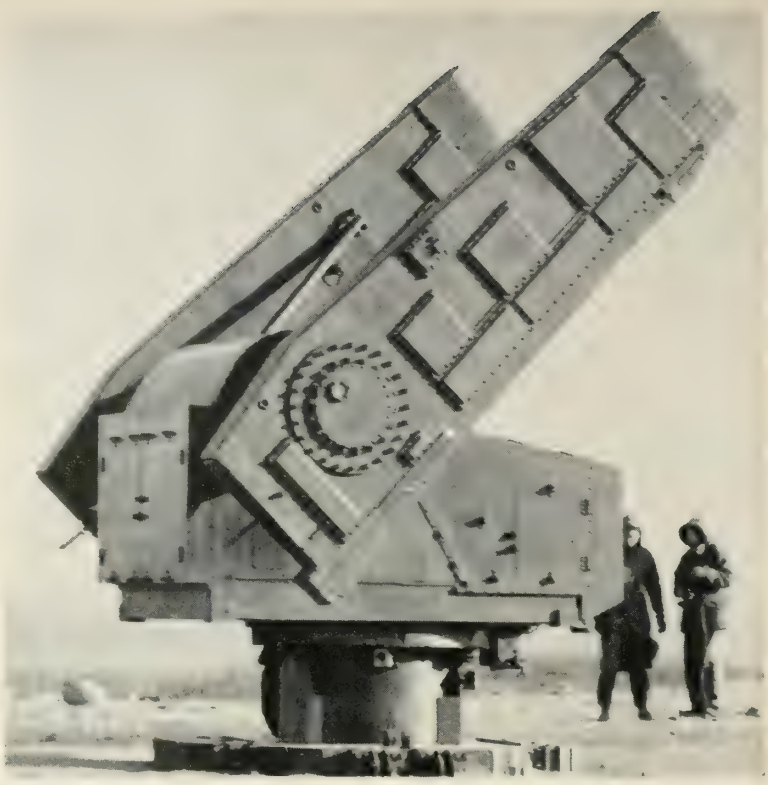
8—Lowering the cost of training.

9—Training men in less time.

10—Permitting standardization and improved team or crew training.

11—Sustaining the proficiency of personnel.

The U.S. Naval Training Device Center (Port Washington, Long Island, New York), under whose technical direction industry has provided more than 30,000 training devices to the military forces, has developed trainers specifically for the guided missile field. Particular effort has been directed toward designing low-cost trainers to reduce the effect of obsolescence resulting from the rapid progress and changes in missiles.



The development of adequate guided missile training devices involves many complex steps in analyzing the details of the training requirements. The type of training device is based on the multiple considerations of a set of variables such as environment, instructor qualification, student level of skill, level of skill to be attained, length of course, curriculum in use, subject material and hours of training.

In weighing these factors, the possible solutions are further subjected to close scrutiny to determine complexity, cost, lead time and useful life in the training program. Finally the most suitable synthetic training equipment is specified. The Naval Training Device Center follows this pattern of operation in the missile training equipment programs it has underway for the Army and Navy.

Industry, too, plays an important part in the development and production of guided missile training devices —by designing, developing, and manufacturing such devices under contract to NTDC.

At first it was necessary to train private enterprise in this new and specialized field. As a consequence many early devices were delayed while a contractor was being educated in the unusual training or simulation techniques involved. Industry needs information and equipment pertinent to the projects it is developing. This problem is caused by a general industrial reluctance to disseminate information and by the necessary security classication which impede the flow of information from one contractor to another.

It would be a great help if missile manufacturers would point out early in the game peculiarities of their missiles that might present serious problems in use, and therefore in training. Advance knowledge of this nature would enable training devices to be properly designed from the start. The dissemination of advanced missile design is of great importance in modifying current training device projects. Prompt relaying of technical information helps place devices in the service schools, the field, and the fleet at a time when they can be most effectively used.

Design of missile simulators calls for a lot more ingenuity than, say, did World War II Link trainers. The simulator for this TERRIER launcher, manufactured by W. L. Maxson Corp., is a full scale working mock-up, designed to fail like the real thing under mistreatment.

The weapon system analysis method for resolving the complex problems inherent in a new missile design has not been in operation long enough to determine its value as compared with other possible approaches.

However, there are additional considerations which should be included when the weapon system analysis is made. Technical consideration should be given *at that time* to development of the necessary supporting training devices.

A brief study of this problem indicates that the cost of training devices is very nearly directly proportional to the cost of operating equipment. Current figures range from 7 per cent to 12 per cent, the higher percentage being due in part to the fact that the training requirement was not recognized early enough, thereby resulting in a "crash program" which increased the cost of the training devices involved.

The ultimate goal of any military training device is to insure operational readiness. The devices developed to assist in the training of men cannot by themselves achieve this goal. They must be intelligently used by competent instructors in an environment for which they were specifically designed.

The success of our military men in the field has earned the admiration and respect of all nations. Prospective enemies are cautious in estimating the strength of the United States, a caution born of experience in operating with or against our land, sea, and air forces. This mark of prestige and efficiency has been largely made possible with the assistance of employing new methods and utilizing new training devices in training at all levels and skills.

The race between nations for technological and production supremacy in the guided missile field has been continuing for several years. It may well be that if the final count down is ever given, the superior training of men will become the determining factor. In fact, this marked superiority, made possible by diligent utilization of properly designed training devices, may be our best guarantee for a lasting peace ★

The Defense that Research Built

Working closely with various government agencies and aviation companies*, The M. W. Kellogg Company has participated in many important research and development phases of the rocket program. This has covered a wide range of missiles and rocket propulsion systems for Terrier, Talos, Snark, Sparrow, and Nike. Kellogg has also produced booster rocket cases and other components.

M. W. Kellogg's long rocket experience, supplemented by this organization's 50-year background of engineering and fabricating high temperature-high pressure industrial products, continues to provide valuable assistance to National Defense.

Including the Navy, Army, Air Force, Allegany Ballistics Laboratory, The Johns Hopkins University Applied Physics Laboratory, and such well-known aviation names as Bell, Boeing, Convair, Douglas, Grumman, Lockheed, McDonnell, Northrop, Republic.

New Fuel Flow Test Equipment

By A. S. Kevorkian, Industrial Engineer
Rocketdyne Division, North American Aviation, Inc.

With the advent of large, liquid-propellant rocket engines such as those now being designed, developed and produced by Rocketdyne Division, North American Aviation, Inc., it has become necessary to develop whole new testing techniques.

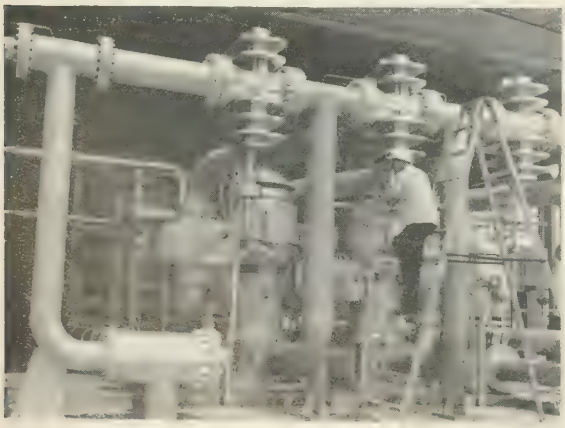
The operation of a large, liquid-propellant rocket engine is essentially a precisely controlled, continuous explosion. Fuel is burned as rapidly as possible producing tremendous quantities of high-temperature gases which flow at supersonic velocities through an exhaust nozzle to produce the high thrusts needed to power today's missiles. In order to assure the proper function of these rocket engines, absolute control of the fuel flow rates must be maintained at all times. Testing components in rocket engines responsible for the control of these fuel flow rates such as valves, fuel lines, pumps, and thrusts chambers themselves, has resulted in the development of a unique testing device, the High Flow Bench.

Rocketdyne, which is now designing, developing, manufacturing and testing large rocket engines for the Army's Redstone missile, NAA's Navaho and the Air Force's Ballistic Missile Program, has also designed the Free World's largest High Flow Bench in operation.

This high flow test unit was built to obtain hydraulic data from rocket engine components. This data consists of accurate flow rates from approximately 100 to several thousand gallons per minute and pressures for various flow conditions ranging up to 1500 pounds per square inch.

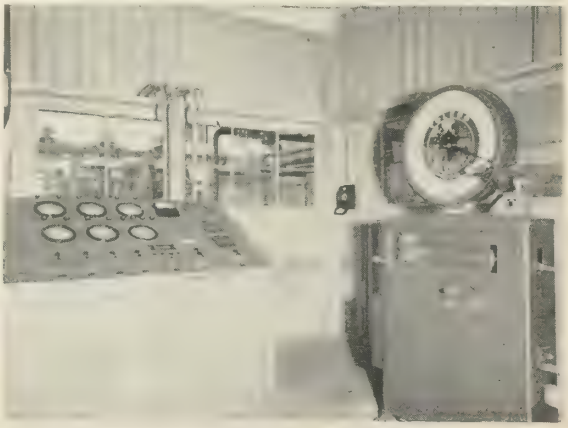
The test medium used is clean water which is circulated through the components by large multi-stage centrifugal pumps. Since water and rocket engine fuel are practically identical in flow characteristics the flow rates and other data obtained with water are easily converted to the corresponding rates of the particular fuels being used in the rocket engines by simply correcting for the specific gravity.

The multi-stage centrifugal pumps are arranged so that the discharge can be piped into a main header with the pumps operating either in a series or in parallel. This enables the personnel testing the rocket engine components to set up the tests to be made with either maximum flow at a given discharge pressure, or maximum pressure at a given discharge flow. The flow rates are further regulated by remotely controlled throttle valves. By means of a bleed-of line or bypass line, any combination of flow rates and discharge pressures within given limits desired for the test, can be obtained. This system, designed and built by Rocketdyne, is a closed or completed circuit, enabling the clean water, after being pumped through the component being tested, to return to a water reservoir, ready for immediate reuse.



To further measure and control flow rates, a six thousand gallon water tank mounted on a scale system, as a part of the high flow unit, is used. Accurate flow rates are determined by means of time span versus pounds of water flow. Water is pumped into the scale tank and accurately measured to the nearest pound. Knowing accurately the amount of water being pumped through rocket engine component, and the length of time it takes to pump the water through the unit being tested, the recording and indicating instruments provide the actual flow data required for the test.

In order to accumulate the necessary data an elaborate system had to be designed and developed by Rocketdyne engineers for this high flow unit. The signals which are recorded or indicated are picked up by means of various instrumentation devices. Reluctance type transducers are used for pressure sensing and resistance type thermometers are used for temperature recordings which provide the necessary electrical signals for recording instruments.



The flow rates are basically measured with the use of orifice plates, venturi tubes and turbine type flowmeters which produce a differential pressure that varies directly with the flow being measured.

This high flow bench, unique in the rocket engine industry, enables Rocketdyne to thoroughly test every rocket engine component used to handle fuel flow rates in perfect safety before the engine is assembled. Because the clean water is used over and over again, testing costs for these components can be kept relatively low without sacrificing the quality or the dependability of the engine.

Rocketdyne personnel operating this high flow bench can handle more than 30,000 gallons of water at a time

Main pipe lines from the three large multi-stage centrifugal pumps used on Rocketdyne's high flow rocket engine component testing unit. Mechanic Harold Hupp sets one of the tremendous valves on this piece of equipment, the largest of its kind in the free world.

Flow rates can be checked accurately by large scale at right. High flow bench operations are controled from console at left. Both units are a part of Rocketdyne's high flow testing unit used to check rocket engine thrust chambers at fuel control components.

and accurately measure it to the nearest quart. Any one of the three pumps used on the high flow bench is large enough to fill a large family swimming pool in the same length of time it takes to fill the average family bathtub.

Thus it is possible to obtain large amounts of accurate information on the hydraulic characteristics of a given rocket engine component from a proven rocket engine design or an experimental design at one central location at relatively low costs, and at the same time correct any malfunctioning parts before the engine is assembled and test fired.

This rocket engine testing facility is not only capable of testing components used in today's large liquid-propellant rocket engines, but is designed to handle upcoming rocket engines now under study which will be considerably larger than the ones Rocketdyne has in production today.

Gas Generators Grow

Speaking before the Chicago Section of the American Rocket Society on December 12, 1956, Mr. Alfred J. Zaehringer, President of the American Rocket Company, Wyandotte, Michigan, presented an up-to-date view of the growing use of solid propellant gas generator. Related to the rocket, the solid propellant gas generator is being used in a wide variety of military, industrial, and commercial applications. They are used on a world-wide level and represent at $10-25 million per year business. In ten years, it is expected to hit $50 million, and in 15 years will be about $100 million.

Outstanding features of the solid propellant gas generator are low cost, high reliability, low complexity, high power-to-weight ratio, ability to operate under a wide variety of environmental conditions, and ease in design. Like the rocket, the solid propellant gas generator is completely self-contained and does not depend on air or oxygen for its operation.

The American Rocket Co. has devoted considerable attention in industrial systems and has pioneered in low-cost, low-pressure, and long-burning time units. It has developed and applied a low combustion temperature propellant that can be operated safely at *any* pressure from one atmosphere on up. With low-cost and high-performance, low pressures can be obtained *directly* without a bleed-down system. Thus, extreme simplicity and high reliability have been achieved. Mr. Zaehringer said that some units had been operated from times of a fraction of a second to over an hour.

Problems and Promises of Liquid Ozone

Scientists and engineers attending the first International Ozone Conference held recently in Chicago were told "we have only scratched the surface of ozone research."

In a welcoming speech to 300 persons from all parts of the world who registered for the conference, Dr. Haldon A. Leedy, director Armour Research Foundation, deplored lack of research in the ozone field. This lack, he said, is rapidly depleting our residue of basic knowledge and is bound to reduce applied research later.

Although the conference covered, in the 65 papers delivered, many of the current techniques for producing and using low concentration ozone in the chemical industry and for municipal water purification, keenest interest was in the production and use of high concentration ozone and the determination of ozone's physical characteristics.

Use of liquid ozone as a "superoxidant" for rocket propulsion fuels would add a new order of magnitude to rocket motor thrust values possible with different fuels. However, questions on what percentage of ozone in an ozone oxygen mixture can be safely handled were refused answers. Speakers said this was "classified information."

Many researchers' reports emphasized liquid ozone's tendency to explode during laboratory experiments. Two reports, however, indicated some way to handle ozone safely may already have been found.

Dr. A. V. Grosse, The Research Institute of Temple University, revealed work being done there for the Office of Naval Research and AF's Office of Scientific Research. Despite reports of the violent instability of ozone when mixed with slight amounts of organic materials, Grosse reported success in premixing cyanogen and ozone. This was then burned to produce a temperature of 5200°K. Sometimes mixtures were left for 24 hours before burning.

Even more surprising to researchers was Grosse's prediction that "crystallization" of a cyanogen-liquid ozone mixture looks feasible. Expected temperature of combustion would be over 10,000°K, he said, and estimated pressure produced would be over "100,000 atmospheres."

Armour m/r learned, has a military contract for ozone research believed to be related to the missile field. ARF started ozone research 15 years ago, and first produced liquid ozone 10 years ago. The Foundation holds a basic patent on the hot copper catalyst method of desensitizing ozone.

It was learned also that ARF has developed a new material for liquid ozone storage containers. Portland cement is foamed to produce a "cement meringue" and is mixed with a Pearlite aggregate. Containers made this way weigh only 5 pounds per cubic foot of material volume.

The development of such containers may indicate current work in progress to apply liquid ozone to missile propulsion.

Atmospheric Ozone

Many ozone study projects are scheduled during the International Geophysical Year. Information is needed on the exact concentration of ozone in various regions of the upper atmosphere, and on production mechanics.

Dr. A. B. Brewer, Oxford University, England, said that variations in ozone concentration at high latitudes are great during the winter season. However, he said, it is not so strong at low latitudes despite the fact that ozone is supposedly produced by photochemical action of sunlight. This occurs even though there is less light in the North during the winter season. This may be related to circulation of air masses.

Study of ozone with regard to high altitude flight are under way at the Air Force School of Aviation Medicine.

Dr. Hans-Georg Clammann, physiologist at the school told of tests during which he breathed a concentration of eight parts ozone per million of air for one hour. The safety level for humans has been set at 0.1 ppm.

Clammann was subjected to the near-lethal tests last July and found his breathing capacity greatly reduced with excessive lung irritation.

Ozone has been found even at stratospheric levels. Flights beyond this point would encounter larger amounts of ozone than can be breathed safely by humans.

Evaluating Propellant Systems

By Joseph Irgon, *The Fulton-Irgon Corp.*

Determining the precise theoretical performance of a propellant system is tedious and time-consuming. It often takes several days for a hand-calculation on a relatively simple propellant, for example, one comprised only of carbon, hydrogen, oxygen and nitrogen. If lightweight metals or other high energy elements are also present, the calculation time may extend into weeks.

In the case of the more complex systems, the difficulties are compounded for two reasons.

The number of chemical species in the reaction products is appreciably increased, thus complicating determination of flame temperature equilibrium composition.

Temperature dependence of each of the many controlling chemical equilibria is far more critical at the elevated temperatures (5000°F) obtained with high energy systems.

A statistical method which provides a quick and accurate means of determining specific impulse has been developed and used with marked effectiveness by the author and his associates. Based on well-known mathematical techniques employed in the design and analysis of industrial experiments, this new approach is proving to be an invaluable aid also in the evaluation of other performance parameters.

These include such properties as characteristic exhaust velocity, hypergolicity, ignition delay, characteristic chamber length, scale factors and other propellant or engine design variables. As a generalized procedure, the method of response surfaces, as it is appropriately called, offers the most feasible means of optimizing the performance parameters under study, irrespective of their nature.

For these reasons, the various short-cut calculation methods that have been applied with moderate success to solid and liquid propellant systems in the low or even intermediate ranges of energy, have proved unreliable for determining the specific impulses of high energy systems (Isp 250 sec.). The approximate methods do not correct sufficiently for the dissociation of the product gases and for significant variations in the concentrations of the products over a small temperature range at high flame temperatures.

Machine computation methods are the most practical means of handling a large volume of propellant performance data. However, for a relatively small number of propellants the operational costs of electronic computer facilities seldom make the evaluation either economical or convenient.

The method of response surfaces provides, with the aid of sequential analysis, relatively simple quantitative models that correlate propellant or engine properties with the pertinent system variables, however complex the system. The models can be represented either geometrically or by mathematical formulae. They are readily deduced from a small fraction of the calculations or experiments required by usual evaluation methods.

Conservative estimates of savings by the new technique run upwards of 60% in the cost of development programs. This is made possible through the judicious selection of systems for study and a scientific evaluation of the data.

Examples of response surfaces in two variables are shown in the contour diagrams of Figure 1. The model is most conveniently represented mathematically, by a generalized polynomial equation that has been best-fitted to the available data by the method of least squares. It is of the form

(1) $Y=A_0+A_1X_1+A_2X_2+A_{11}X_1^2+A_{12}X_1X_2+A_{22}X_2^2+\ldots,$

where the A's are constants (multiple regression coefficients) associated with the various variables or combinations of variables X_1, X_2, X_3 . . ., and Y is the "response." Expression (1) is simply the Taylor's expansion of functions such as those representing the systems of ridges or peaks shown in the figures. The contour lines that represent constant values of the dependent variable Y, are referred to as the responses to the independent variables X_1, X_2, etc.

Illustrating the role of factor dependence, ridge systems of the type shown characterize most systems encountered in scientific and engineering work that involve two or more variables. The situation which can occur in many variables becomes progressively more complicated, as the three-variable contour diagram (Fig. 2) suggests. The latter arrangement can be regarded as being built up from two-dimensional contour diagrams.

In the absence of specialized knowledge, the method of response surfaces,

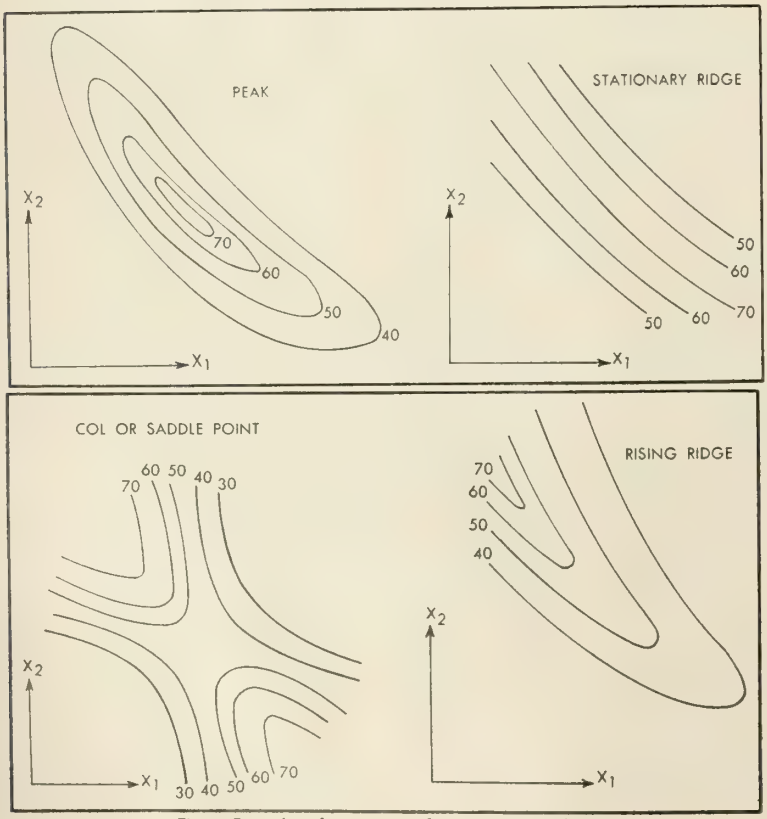


Fig. 1. Examples of response surfaces in two variables.

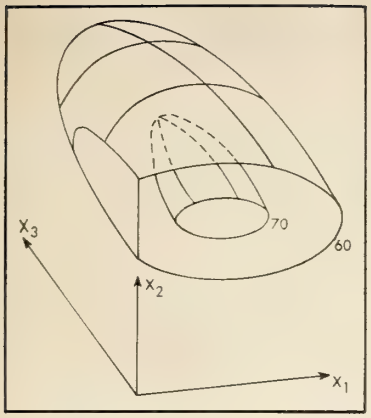

Fig. 2. A Three variable contour diagram.

which automatically takes into account the multi-factor problem, enables the optimum regions shown in the illustrations to be evaluated with considerable economy in effort and time. The conventional method would be to approach the optimum region on a hit-or-miss basis, which would require many more calculations or experiments to be performed than are actually needed.

With several factors to be varied, the possible combinations can number in the thousands. In such circumstances, it would be most difficult to determine the optimum region by the usual "one variable at a time" approach.

The investigator is apt to find himself figuratively stuck on a ridge, often without realizing it, having assumed some lower point of the ridge or peak to be the optimum. This cannot happen when employing the statistical approach, as it immediately provides the most pertinent details of the overall picture and minimizes the effort spent on unimportant features of the correlation.

Such an analysis of factor dependence in conjunction with theoretical knowledge often leads to a better understanding of the basic mechanisms governing the systems or processes under study.

It is apparent from the foregoing that the method of response surfaces is a powerful tool in analytical as well as experimental programs concerned with complex multi-factor problems and should, therefore, prove to be of increasing usefulness to the propulsion field.

Propulsion Notes

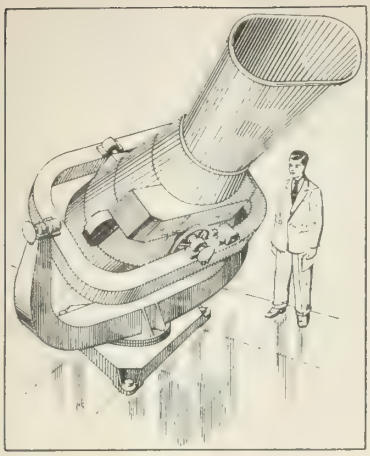
By Alfred J. Zaehringer

Look to Penn Salt to introduce a new fluorine propellant. A derivative of fluorine monoxide, the compound is said to avoid the difficult handling properties of liquid fluorine. Incidentally, one midwestern university supposedly has made small scale runs on liquid F_2 combinations. Early investigations have shown that even solid fluorine reacts hypergolically with hydrogen. Present difficulties with fluorine stem from the fact that reaction with water produces ozone which then bangs off.

Organic perchlorates appear to be heading for trials as liquid monopropellants. There have been attempts to use it as a burning rate accelerator for double-base propellants. Now, a downriver Detroit chemical manufacturer is looking into electrolytic production methods.

Cal Tech scientists claim that successful runs of Diver's Solution (ammonium nitrate dissolved in liquid ammonia) have not panned out. Troubles: difficult ignition and unstable combustion. A 75% solution has a calculated performance of 175 sec, is smokeless in operation, and is extremely cheap and easy to handle and store. However, the catch seems to be operating at temperatures above the boiling point of ammonia (about—25°F) and yet above the decomposition temperature of ammonium nitrate (about 338°F). The California group believes that success hinges on finding a powerful catalyst to promote smooth reaction between these "humps."

NACA has been running ammonia in regeneratively cooled rocket motors with heat transfer rates of 2.5 BTU/sq. in./sec. They used a novel light-weight engine fabricated from hydraulically formed sheet metal.



Ignition of solid propellants by detonating gases has not proved satisfactory for many combinations. Reason: low radiation intensities and absence of hot solid particles. For this reason, gunpowder continues to be a standard solid propellant igniter ingredient although the gasless or slag igniters offer promise.

Longest duration ever achieved by a large solid propellant rocket has been announced by Phillips Petroleum Co. It is claimed that a new design concept was used to accomplish this result. Operational solid propellant rockets have averaged 30 sec burning time, with lab reports of times up 5 minutes.

Phillips solid propellant materials cost is about 13¢/lb. This cost does not include materials handling and processing. Big limitation in the process is that extrusion rather than casting is used.

Honest John presumably could easily be launched from a sub today but its range (18-20 miles) will limit use to immediate coastal targets. The Soviet T-7A, also a solid propellant rocket, has only a slightly greater range (50 miles). It is assumed that our *Sergeant* solid rocket, now under development, will have a range comparable to the T-7A.

A nuclear test site is said to be in the works at the new Thiokol facility in Idaho. It is not known who will operate the facility. However it is certain that the program will pertain to nuclear rockets or the aircraft nuclear propulsion program.

Vanguard Satellite Tracking Camera Developed

By Henry P. Steier

Key to whether the artificial earth satellites will tell us anything really new about the earth itself is the ease and accuracy with which they can be tracked.

Data on ambient conditions at orbital altitude can be telemetered to earth, but getting new facts about the earth depends upon observations of the satellites made from the earth.

Using an accurate computing system, the position of the satellite as checked by observing stations is expected to give information of previously unobtainable accuracy.

Determination of station location relative to the center of the earth and to each other is expected.

Out of a research program based on the observation positions of masses on the earth's surface, shape of the earth, distribution of mass within the earth and atmospheric density should be determined with new accuracy.

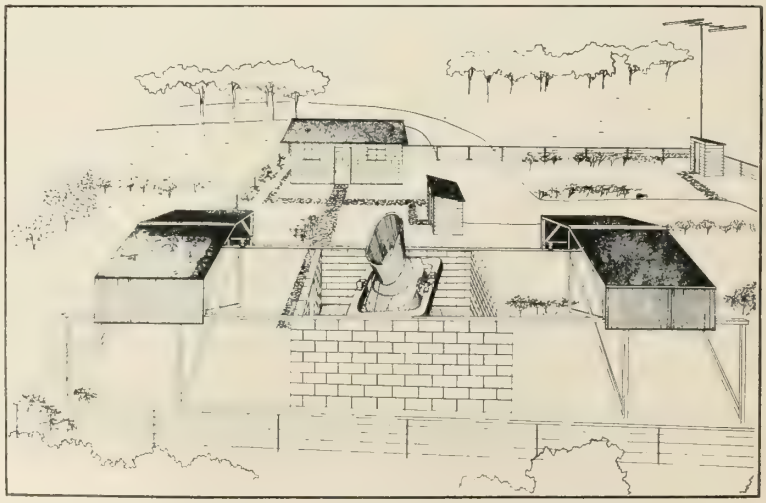
Smithsonian Astrophysical Observatory (SAO) has been assigned responsibility for obtaining the observation data and processing it. Twelve or more special satellite tracking cameras will be employed in a precision optical program designed to photograph the satellites as they pass over each station.

In addition, a visual observer organization will be set up under the direction of a National Committee of Visual Observers. They will use binoculars or monoculars and an accurate time source.

The visual observations organization will be headed by Dr. J. Allen Hyne of SAO and directed by Mr. Armand Spitz. During the final stages of the satellites' lives when they are rapidly spiraling to earth, the visual tracking work is expected to be very valuable.

Exact locations of all camera stations has not been revealed. Observation points for cameras are reportedly being considered for Alexandria, Egypt, Casablanca, Morroco, Hyderabad, India, and in the Union of South Africa and Australia. Best sky transparency and freedom from clouds is important.

Camera Details



Goal of the tracking effort is to obtain positions occupied by the satellites during each orbit to within seconds of an arc and a few thousandths of a second in time.

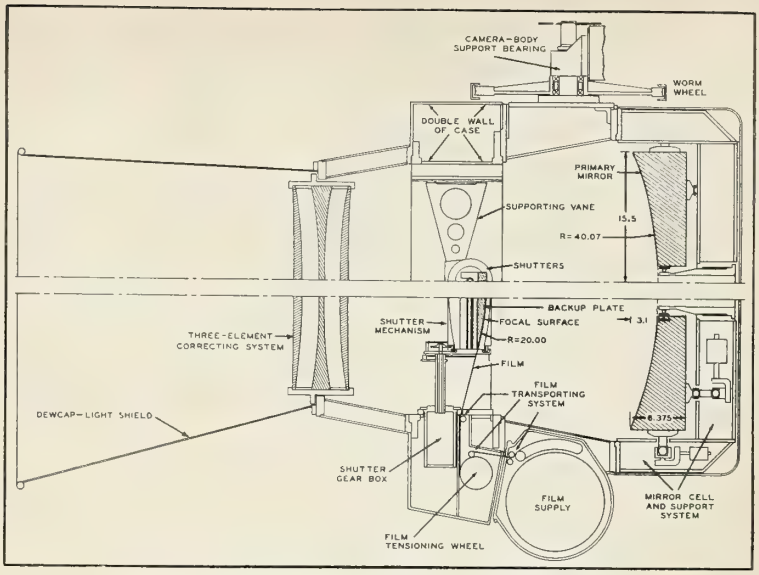
SAO has designed a special camera to fill the need for a photographic technique that can observe a satellite with an assumed perigee of 200 miles and apogee of 1500 miles.

Optics have been designed by Dr. James G. Baker of SAO, and the instrument by Joseph Dunn and Associates, Cambridge, Mass.

The Baker-Nunn camera, as it is known, uses a photographic Schmidt system with 20 inch aperature, 31 inch Schmidt mirror and focal length of 20 inches. Performance at the edge of the camera field is said to be better by 100 times than a classical f/1 Schmidt.

First of the cameras is nearing completion at SAO in Cambridge, Mass. Its

Artist's conception of a satellite tracking-camera station. Sliding roofs would cover camera during inclement weather. Antenna would be used for communication with Vanguard Computing Center in Washington, D.C. or other camera stations and visual observer stations.



optics and film exposure mechanism was designed for taking both stills and moving pictures.

This will be done during evening and morning twilight hours when satellite visibility is at maximum. Depending upon whether bright or dark twilight conditions exist, and the satellite is far or near, different photographic techniques will be used.

A 20 inch sphere with an albedo (reflectivity) of 0.6 would have a photographic magnitude of 6.3 at 200 miles and a visual magnitude of 5.7. At 1500 miles visual magnitude would be 10.1.

Limit of vision with the eye is 5.7. Anything with a higher magnitude number would not be seen.

Angular velocity at 200 miles would be 87.8 minutes of an arc per second. At 1500 miles it would be 8.7 minutes of an arc per second. The apparent speed would be meteor-like at 200 miles and slower at 1500.

Section view of satellite-tracking camera showing film transport and shutter arrangements and Schmidt optics.

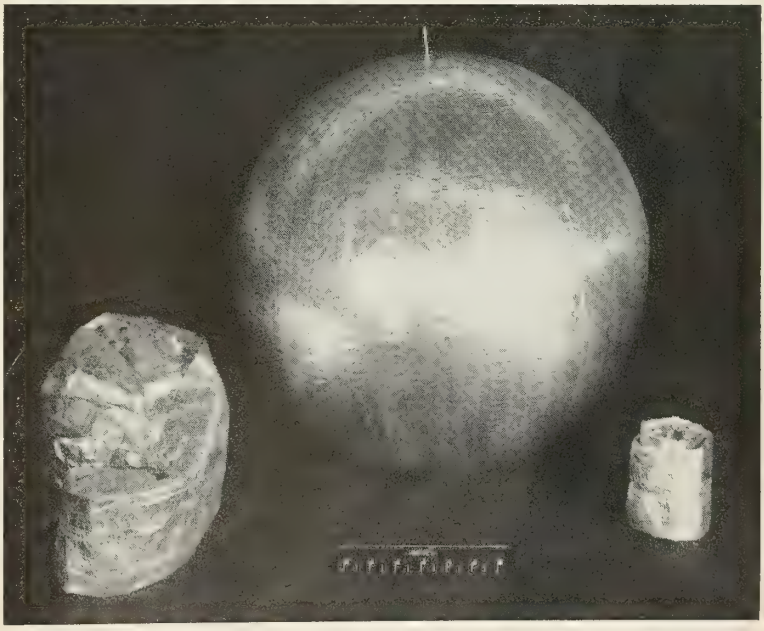
High Optical Speed Needed

The optical speed necessary to photograph the satellites under these conditions is difficult to achieve. To meet the problem of film fogging that would occur with exposures longer than 1/5 second, the camera will use continuous Kodak Tri-X film which can be transported in steps at different cyclic rates. These are determined by light conditions.

Two shutters will expose the film. A gross shutter will operate during a transport cycle and be open for 20 per cent of the cycle. In a one-second transport cycle the exposure would be 0.2 second. In the longest cycle of 5 seconds, exposure would be a full second.

During the gross shutter operating time a rotating barrel-type shutter with a period five per cent of the total transport time will interrupt the exposure for periods of 1/100 second.

This will give time marks spaced 100 microns (.0039 inch) in the satellite trail on the film. Synchronized with the rapid shutter will be a stroboscopic presentation of a crystal clock face photographed directly on the film strip. The clock accuracy will be 1/1000 second.



When the satellites are fainter than maximum, the fixed position will not be used. The camera will be moved in a partial motion rather than continuous.

This is because a star field will be photographed as a location reference for the satellite position. Continuous movement would show the brighter stars as long trails and faint stars would be lost altogether. The camera movement could be oscillatory or discontinuous.

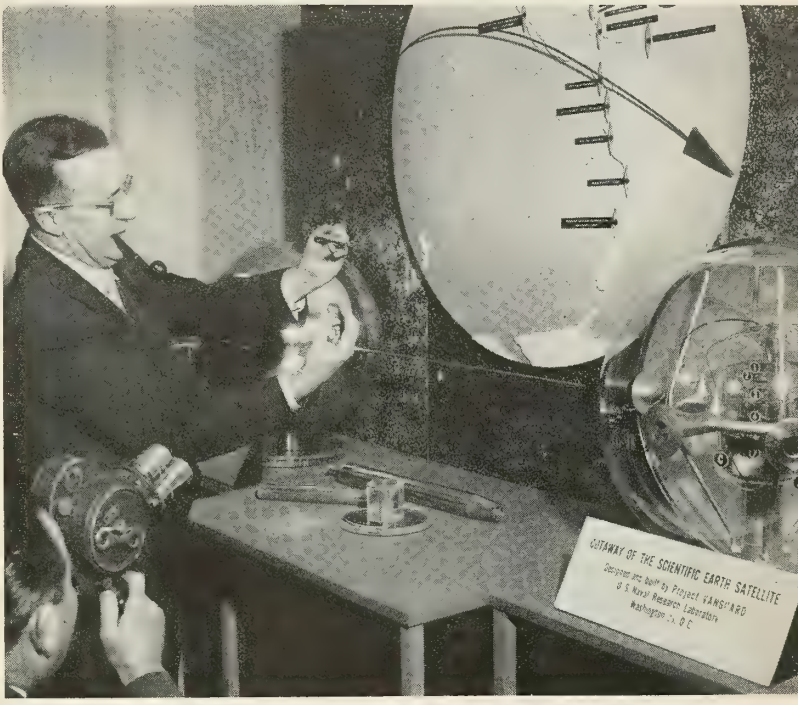
The optical axis of the camera will be allowed three motions: altitude, azimuth and tilt.

An orbit calculation and prediction center located at Cambridge will act as the nerve center for communications between the Vanguard Computer Center in Washington, D.C. and between different visual and camera observation points in the world. This collection and correlation of data is one of the most important parts of the IGY Program.

Data will be rapidly analyzed as soon after the photographic work as possible. This will aid planning for later satellites which may need alterations to get the most out of them.

The new camera will be especially useful in tracking these balloon-like sub-satellites that are scheduled to be released by earth satellites. The 20-inch diameter aluminum coated plastic bags, inflated after release at altitude, contain no radio equipment and will have to be tracked visually. NACA, who developed them, expects to gain valuable upper air drag and density data by following their movements.

Plastic mock-up of an advanced design IGY satellite with scientific instrumentation. Internal bracing will support four 1/4-wave antenna dipoles as well as a central housing for plug-in modularized telemetry and Minitrack transmitter circuitry (No's 1 to 6). Ports (A and B) will expose solar cells and Lyman-Alpha instruments for orientation and ionization measurements. "C" and "D" identify instruments on the skin for measuring meteoritic erosion and temperatures.



Vanguard Instrumentation

Dr. JOHN P. HAGEN, director of Project Vanguard, demonstrates with a scale model the separation sequence of the satellite and third-stage rocket motor. Behind Hagen's hands is a full-scale satellite with antennas in erected position.

Cutaway of a satellite showing internal construction is at right foreground. Geographic diagram on wall shows location of Minitrack ground radio tracking stations and direction of a typical satellite orbit. All Minitrack stations will be located in the Western Hemisphere and will provide the Vanguard Computing Center located in Washington, D.C. with data on satellite locations.

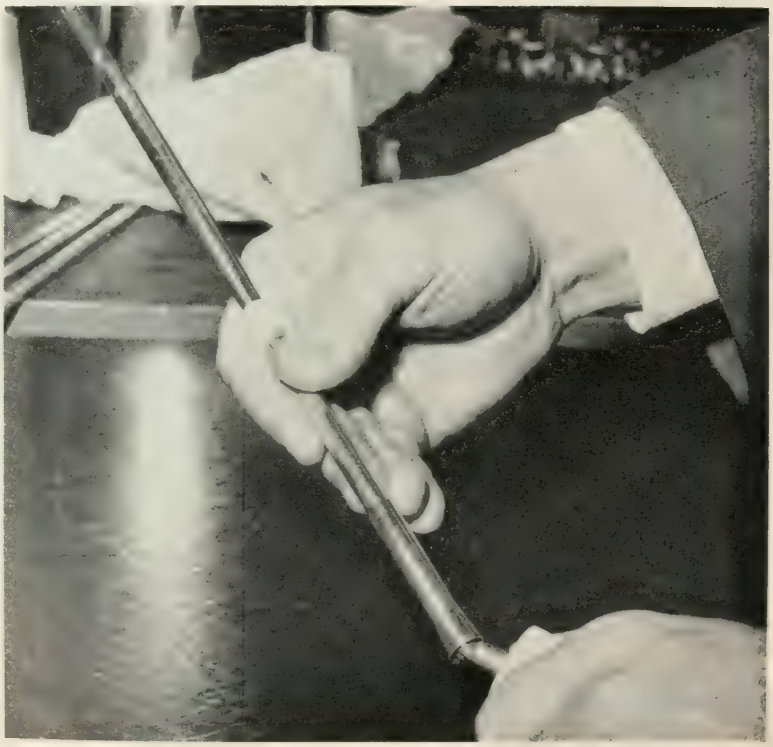
Twenty minutes after meridian passage of the satellite over a Minitrack station two bits of angular data and time of measurement will be sent to the Center.

With these data an International Business Machines Corp. 704 computer will calculate times of arrival, zenith angle, angular velocity and location of a favorable acquisition direction for optical tracking stations located in many parts of the world.

ROBERT H. BAUMANN, Group Head, Satellite Engineering Consultant Staff, Naval Research Laboratory, plugs a modularized circuit into a satellite's gold-plated aluminum astrionics container.

Astrionics for telemetry coding and transmission is designed in circular layer modules. In this way various circuits needed for a variety of scientific measurements to be made with different satellites can easily be accommodated.

This satellite prototype is being readied for pressure, vibration, and shock testing. The assembly will also be centrifuged and thermocycled to determine the satellites' fitness for forecasted conditions in outer space.



Circular printed wiring boards that go into the satellites' astrionics housing have transistors and other components fastened directly to the boards. Pin contact boards fastened directly to the circular boards aid ease of interconnecting various circuit layers.

Light colored material at top of astrionics housing is Kel-f plastic. It is a low thermal conducting material for heat isolation and support of the housing.

"T" shaped Kel-f plastic pieces will fasten to internal bracing and aid centering support of the housing.

To the right—Back through the years, Naval research has been one of the most productive scientific investigative operations at the nation's disposal. Its latest project is The VANGUARD Satellite. The diagram on the next page shows its present-day organization.

→

The four 1/4-wave dipole antennas carried by the satellite will be folded during flight of the VANGUARD vehicle to orbital altitude.

After separation of the satellite from the third stage rocket motor, the dipoles will be erected. They will be activated by a spring-loaded hinge near the base of each dipole.

After the dipoles spring into place, funnel-shaped sleeves near the hinges slip down and lock the dipoles in straight-out position.

Antennas are located around the equator of the satellite and spaced 90 degrees apart. This configuration is expected to give circular polarization needed for best radio tracking.

Satellite orientation with respect to the sun, as detected by solar cells, and ionization as measured by Lyman-Alpha instruments should add wholly new knowledge of microwave refraction indices at satellite altitudes.

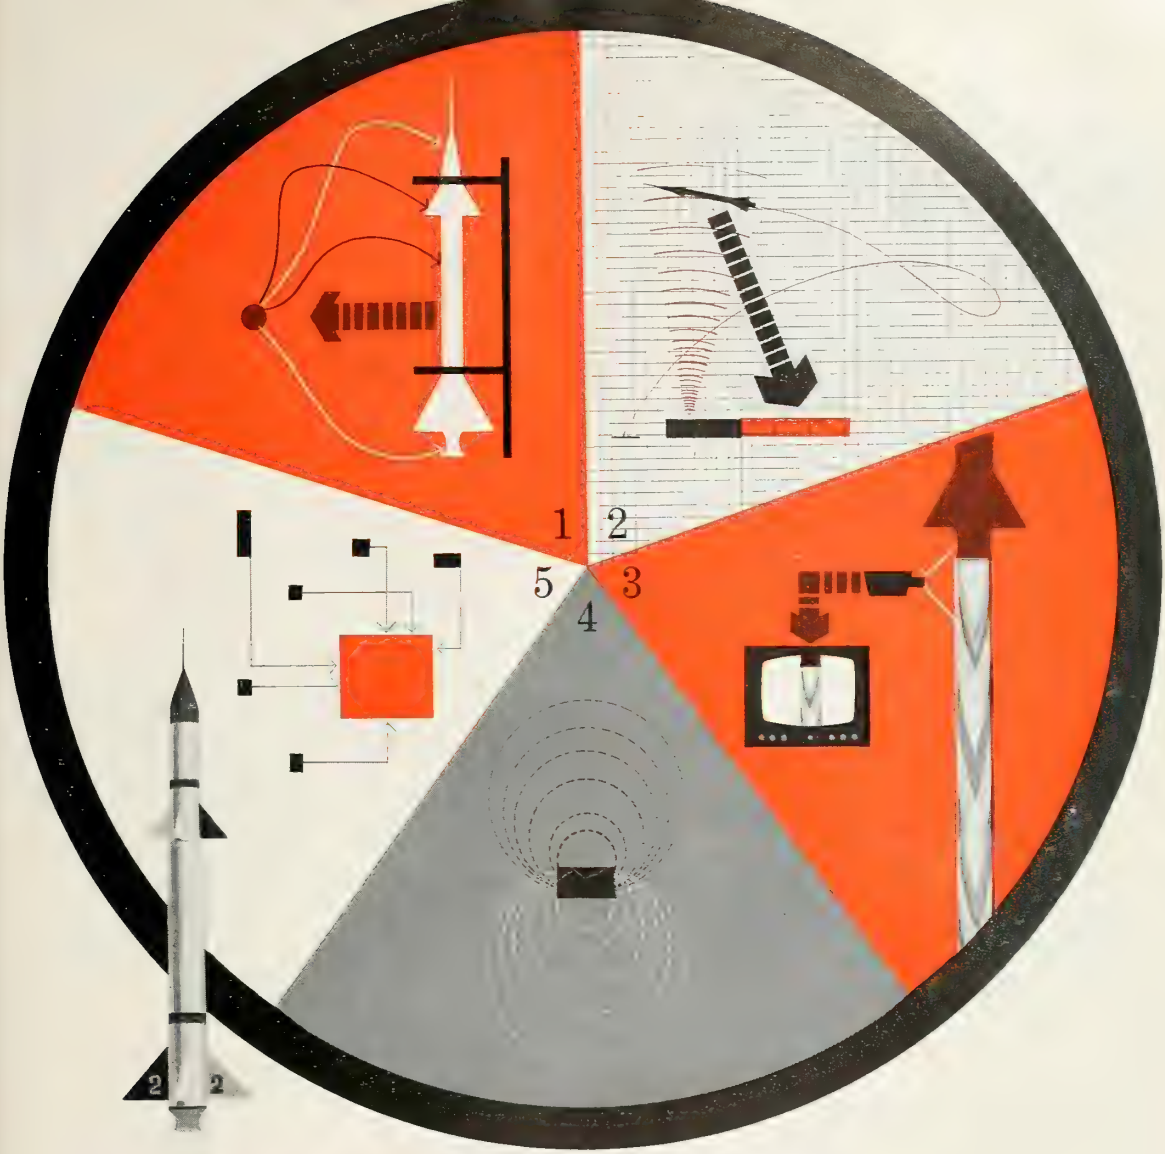
Astrionics

By Henry P. Steier

Anti-missile missiles will compound to new proportions the reliability and life headaches of electron tubes. *Nike* battery Commanders are already wrestling with these problems. A typical *Nike* system uses 3,500 tubes. Each plays a vital role. Operating and maintenance costs vs. readiness factors must be considered. *Nike* stations do not stay "on the air" 100 per cent of the time. Defense planning takes into account warm-up time needed for readiness.

With the anti-ICBM missile, tube life-reliability considerations will grow drastically. Radar rf generators used for *Nike* now develop power in terms of 1,000's of watts. The *Nike Hercules,* reportedly the anti-ICBM design under development for the Army, will need rf of millions of watts to seek and destroy its target. *Nike Hercules* stations would probably stay on the air around the clock since readiness time is nil. Tube engineers will soon have to face the need for the ultimate in life and reliability (as well as the extremely high power), since there will be no down-time for checking tubes.

Astrionics information was cited recently as the weakest link in the body of information available for handling ICBM offense and defense. Dr. F. J. Tischner, Ohio State University and formerly with Redstone Arsenal's electronics laboratory, said although we have radar for detection, the all important determination of exact position and velocity is very difficult. Among the weakest links are wave propagation and antenna design information.



Usual approach to determination of wave propagation is through the index of refraction of the propagating medium. Microwave optics in hypersonic flight—above Mach 10—must cope with what Dr. L. M. Hartman, General Electric Co., Missile and Ordnance System Dept., calls a "monstrous lens" formed of dissociated gases in the stagnation region around the object. Electron density which regulates index of refraction begins to be considerable at Mach 10 and changes with altitude, so result would be a complex constantly changing electron lens. Besides finding a way to communicate with rockets through such a lens, the antenna would have to withstand 8,000°K.

•

One member of scientific fraternity does not think much of using solar cells for getting astrionics power from the sun. Pointing out that only about 2 kw per square yard is available, and that solar cell efficiency is quite low, he reminded his listeners that "fast growing Iowa corn uses sun energy better than semi-conductor devices."

•

Optical tracking cameras for the IGY satellites are designed but none have been completed. The first is being constructed by the Astrophysical Observatory, Smithsonian Institute, with optics supplied by the Perkin-Elmer Corp. The 12 cameras to be built will photograph satellites as they pass "with meteor-like speed" in the words of Dr. K. Heinze of the Institute. Cameras will use Schmidt optics with a 30 inch field and Kodak Tri-X film. Both satellites and reference stars near them will be photographed.

Here's the big "PLUS" for engineers...

New $40,000,000 plant for Convair-Astronautics facility, soon to be completed.

New $300,000 Convair San Diego seaplane towing tank, first unit of complete hydrodynamics laboratory.

New $3,500,000 supersonic wind tunnel now under construction at Convair San Diego.

La Jolla Cove, one of many beauty spots within easy reach of San Diego.

the advanced projects and facilities, PLUS beautiful, year-round San Diego living

Tremendous projects at Convair San Diego include the F-102A Supersonic Interceptor, the Metropolitan 440 Airliner, the Convair 880 Jet-Liner, and a far-reaching study of nuclear aircraft. To aid engineers in these projects, big new facilities are being added to the already vast Convair San Diego plant. These include a huge installation for research, development, production and testing of the Atlas intercontinental ballistic missile, an elaborate new seaplane towing tank, and a new supersonic wind tunnel.

You'll find an ideal engineering "climate" at Convair San Diego – excellent salaries, comprehensive personal advantages, engineering policies to stimulate your professional growth, and a rewarding association with men who are outstanding in their engineering fields.

Add to all these the big "plus" of delightful living in sunny San Diego, where America's kindest all-year climate gives you and your family full enjoyment of beaches, mountains, desert resorts, Old Mexico, Hollywood, and many other fun possibilities. For the big "plus" in your future, send full resume to H. T. Brooks, Engineering Personnel, Dept. 2000

Aerophysics

By Seabrook Hull

The optimum solution to ICBM and IRBM reentry may lie in the use of plastics rather than exotic metals. NACA hypersonic test vehicle experiments have produced encouraging results. Of the two most promising organic groups being researched, epoxy resins have relatively high melting points, particularly with curing. Fluorinated plastics, already fully oxidized by fluorine, are chemically inert under the high temperature conditions of atmospheric reentry.

Both melt relatively slowly, due mainly to the fact that the thin fluid melt layer has a very slow heat transfer rate. Certain compounds in both groups sublime with profitably high specific heats. This not only facilitates reentry design but fits the concept of manned hypersonic vehicles entailing disposable parts. Laminating materials include tempered glass and quartz. Stainless steel, nickel-cobalt or molybdenum alloy screens might be used for structural backing.

The beauty of this approach to hyperthermantic flight is its dependence on well-known industrial techniques and readily available materials. And, importantly, it's cheap.

•

Time as an absolute standard is being challenged. Ephemerous time is based on there being 31,556,925.975 seconds in the year 1900; universal time, on there being 86,400 seconds in a day. The relationship of universal to ephemerous time is a standard that has never been seriously questioned, but on which all science is based. A 5-to-10 year experiment just now beginning, however, seeks to find if time as man has defined it is so standard after all. Like the solar system—corrected for Relativity, known variations, etc.—is consistant, so is the state of the atom. Both, reduced to absolute terms, bear an unchanging relationship—or so we have assumed these many years.

Current continuing measurements of the frequency of the cesium atom at Washington's Naval Observatory may, in a few years, prove this isn't so. If it does, Relativity limitations may become potentials; man's knowledge of his infinite environment may be grossly expanded and the rate of scientific progress accelerated exponentially.

If this seems remote, remember: It was Rutherford's work in the late 19th Century and Einstein's in 1905 that ultimately lead to man-made nuclear power during World War II.

•

The practical nuclear rocket has been brought closer by a 12-man California University team under Prof. Luis W. Alvarez. Without the 100,000,000° temperatures now needed but with the same immense energy release, catalytic use of the negative mu meson "cold-fuses" heavy and light hydrogen into helium. Needed: A controllable production source of the scarce, short-lived mu meson. Outlook: Optimistic.

•

If anyone thinks ballistic missiles are "all-that-different" from military aircraft, the cost of research and development of "fool proof" guidance for long range missiles runs every bit as high as it does for the little black boxes in SAC bombers, interceptors, etc.

To the ENGINEER of high ability

Through the efforts of engineers The Garrett Corporation has become a leader in many outstanding aircraft component and system fields.

Among them are:

air-conditioning

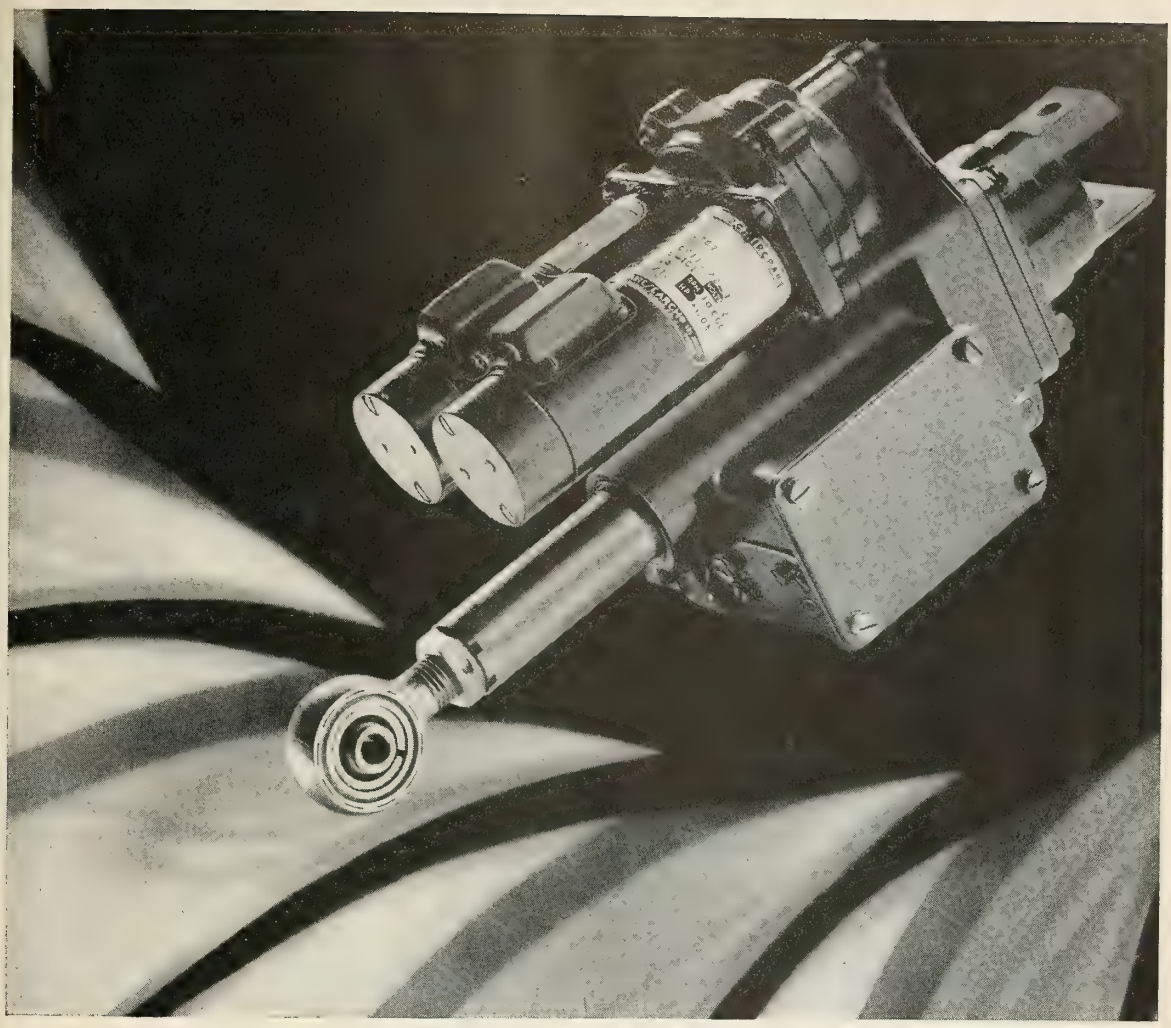
pressurization

heat transfer

pneumatic valves and controls

electronic computers and controls

turbomachinery



The Garrett Corporation is also applying this engineering skill to the vitally important missile system fields, and has made important advances in prime engine development and in design of turbochargers and other industrial products.

Our engineers work on the very frontiers of present day scientific knowledge. We need your creative talents and offer you the opportunity to progress by making full use of your scientific ability. Positions are now open for aerodynamicists ... mechanical engineers ... mathematicians ... specialists in engineering mechanics ... electrical engineers ... electronics engineers. For further information regarding opportunities in the Los Angeles, Phoenix and New York areas, write today, including a resumé of your education and experience. Address Mr. G. D. Bradley

Four-speed actuator

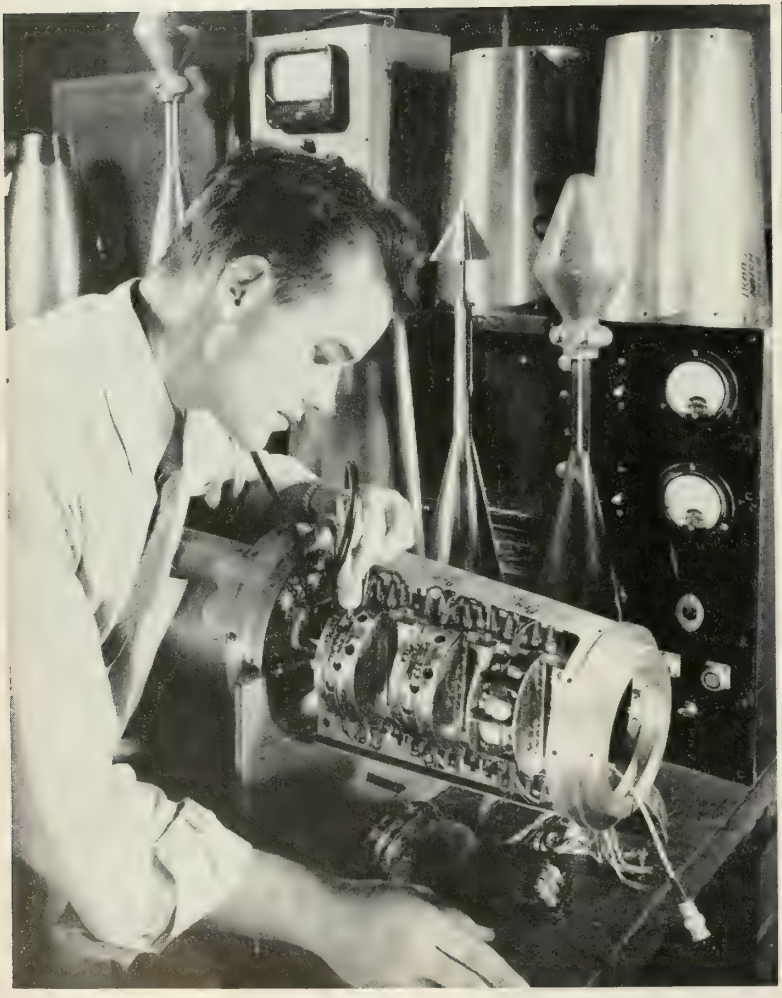
AiResearch two-motored unit provides automatic control plus an instantaneous manual override at the work end of its Air Data System

During high-speed flight, where control is so delicate it is often by trim surfaces alone, immediate response under emergency conditions is of critical importance. The actuator shown allows immediate pilot override of the automatic system without any disconnect activity or mechanical clutching device. If necessary any one of four speeds may be instantaneously selected. The unit operates with complete dependability at ambient temperatures up to 300°F.

AiResearch actuators operate on split-field or permanent magnet DC motors, on AC servo motors or on single-phase, two-phase or three-phase AC motors. They can supply feedback signals to the control and be provided with neutral positioning and light-switches.

We are now engaged in the development of Air Data Systems of all types, assuming full system responsibility. Because we manufacture the entire system, including transducers, computers and actuators, you are assured of the utmost in system compatibility.

Outstanding opportunities for qualified engineers. Write for information.



THE GARRETT CORPORATION

AiResearch Manufacturing Divisions

Los Angeles 45, California • Phoenix, Arizona

Designers and manufacturers of aircraft systems and components: REFRIGERATION SYSTEMS • PNEUMATIC VALVES AND CONTROLS • TEMPERATURE CONTROLS • CABIN AIR COMPRESSORS • TURBINE MOTORS • GAS TURBINE ENGINES • CABIN PRESSURE CONTROLS • HEAT TRANSFER EQUIPMENT • ELECTRO-MECHANICAL EQUIPMENT • ELECTRONIC COMPUTERS AND CONTROLS

SUBCONTRACTORS' GUIDE: Missile Electronics and Astrionics

Like a doctor checking a patient, this electronic specialist making careful adjustments to the telemetering brain of an NACA test missile symbolizes the critical importance of electronics and astrionics to the new age. In some major missile programs guidance development takes nearly two-thirds of the total project budget. The listing that starts to the right includes major U.S. companies doing missile work in the general fields of electronics and astrionics. Included are not only the names of the companies and their addresses but the names of their subcontracting officers as well. This is another *m/r* special service to its subscribers.

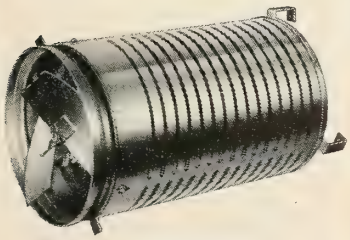
When You Count Time in Terms of λ



MISSILE COMPONENTS HYDRAULIC TEST STAND

Custom-designed for a specific use—the prolonged testing of hydraulic components at pressures in excess of 3,000 psi and temperatures up to 450° F.

HYDRAULIC SERVO-MECHANISMS TEST STAND

designed to test components and flows up to 10 gpm at 3,000 psi with simultaneous static pressures available to 10,000 psi. Dynamic system pressures up to 5,000 psi are available at reduced pump flow rates.

SUN ELECTRIC POWER ABSORBER

for continuous duty operation at 13,500 W. Takes up only ½ cu. ft. of space and weighs 1 lb. per KW. Adaptations are already in use in the "Snark" and "Redstone" missiles systems programs.

Up there where time is expressed in terms of distance inconceivably short, you are in SUN territory.

Functional testing of components in the aeronautical and astronautical fields demands positive knowledge from design engineers and positive skill in manufacture. SUN ELECTRIC CORPORATION, with years of experience in prime mover component testing, fulfills both desiderata.

SUN'S engineers can help you when you are faced with problems in the following areas:

- **—Ground support test equipment for missiles systems**
- **—Quality control test equipment for missiles component functions**
- **—Reliability-test equipment for the above**
- **—Firing stand test equipment**
- **—In-factory functional test equipment**

Call in a SUN engineer and let him work out a solution with you—you'll be glad you have his expert help.

And λ the time factor. SUN'S service is *fast*. We can work to your deadline!

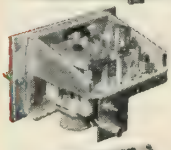
In a future issue m/r will publish a subcontractors' guide to manufacturers of launching gear & other missile components



Unhampered by traditional thinking, TELECHROME engineers have developed an entirely new concept in telemetering equipment. Today's new environmental conditions and distances for missiles require new designs. TELECHROME units are unequalled in compactness, ruggedness* and dependability. Because of their superior qualities these highly efficient units are replacing equipment of other manufacture.

French Coleopter Missiles Underway

Missile derivations are planned for SNECMA's "Flying Atar" VTOL test vehicle. Shown above is the original P1 version of the French device. To date it has made some 200 takeoffs and landings. A piloted version, the P2, is ready for its test program while a more refined version, the P3, with a full cockpit with a rotating seat will be the next step.

From the P3 SNECMA will build an experimental aircraft with an annular wing, the C 450. This coleopter will be subsonic. It will make vertical takeoffs and landings but will fly like a conventional aircraft. Subsequently SNECMA will build a coleopter with a ramjet as well as an afterburner-equipped Atar turbojet. The ramjet will be installed in the space between the jet engine and the annular wing.

Eventually the "Flying Atar" will be developed into a Mach 3 vehicle, either in the form of a missile or a piloted aircraft. In five to ten years SNECMA can envisage civil applications of the formula. The most important use for the coleopter type of vehicle, however, is likely to be military in view of its small size and outstanding performance.

World Astronautics

By Frederick C. Durant III

Outside of the U.S. only two countries have reported work on three-stage rocket vehicles. One of these was the Japanese *Kappa* rocket program, (m/r October 1955). The other rocket, a French one, is known as the *Monique*. The program has been under way for more than a year but little information has yet been released. Use of staged rockets introduces the designer to problems of clean separation and smooth ignition at space-equivalent conditions.

Japan's initial series of rocket tests in preparation for the IGY came to a successful conclusion in December with the launching of the seventh Kappa 128-JT at Michikawa. The test program is expected to be resumed in March when a double Kappa rocket will be launched.

•

British physicist Arthur C. Clarke is known equally well for his writings in science (EXPLORATION OF SPACE) and science-fiction (THE CITY AND THE STARS). Completing a five months' lecture tour of the U.S. he met with key individuals of Project *Vanguard* at the Naval Research Laboratory and Martin, Baltimore. In addition, he talked with those at The National Academy of Sciences and The National Science Foundation concerned with the overall U.S. program for IGY satellite vehicles. First hand impressions gained will end up in a forthcoming book on satellite vehicles to be published this fall by Harper and Brothers. The tentative title is THE MAKING OF A MOON.

•

On New Year's Day, Dr. J. Allen Hynek, Associate Director of the SAO, left for a month's tour of South America to follow up preparations for the official optical tracking program and to evaluate the interest in volunteer observing teams. First stop on his trip is Buenos Aires, where Hynek will meet with the Argentine IGY Committee Chairman and Professor T. M. Tabanera.

•

Einstein's Restricted Theory of Relativity (1905) contained one theorem entitled "The Behaviors of Measuring Rods and Clocks in Motion." Interpretation of this theorem has led to periodic controversy. The question is if a "clock" moving at near-light speeds would keep slower time than a "clock" which, relatively, is stationary. At the Seventh Congress of the International Astronautical Federation at Rome last September there was speculation on human aging rates under the same relative conditions. Kurt R. Stehling has a neat, witty summary of articles on the matter in the January issue of the ARS JET PROPULSION. Prominent scientists take contradictory stands. The ability to hurl sub-atomic particles at near-light speeds may provide data to settle this intriguing paradox once and for all—in any event, probably before any future generations have to test the time dilation effect in manned space vehicles.

•

Eighth Annual Congress of the International Astronautical Federation will be held at Barcelona, Spain, October 6-12, 1957. A focal point for technical papers and discussion on rocket and astronautical subjects, with representatives of twenty-one countries, the size of the Congresses has grown rapidly. More than 70 U.S. visitors and delegates were present at Rome. With the advent of the IGY and the anticipated *Vanguard* launchings this year, the Barcelona Congress is expected to be an outstanding event. A brochure describing the history and aims of the IAF is available upon request to: IAF, 35 Lowell Road, Concord, Mass.

European Rocket Engineers in Argentine Astronautics

By Frederick C. Durant, III

SOUTH OF THE equator the world center of astronautical interest is in Buenos Aires, Argentina. There, the Asociacion Argentina Interplanetaria (AAI) has achieved national recognition for its many diverse activities.

Right now, the AAI is busy preparing for the optical tracking of the U.S. satellites. During the Seventh Congress of the IAF held at Rome last September (M/R October 1956) Professor Fred L. Whipple, director of the optical tracking program for the U.S. satellites outlined the need for volunteer tracking teams. The AAI was one of those IAF Members interested in the problem.

Founder and energetic President of the AAI is Prof. Teofilo M. Tabanera. In 1930, as a young mechanical engineer, Tabanera wrote his first article on the possibilities of space flight. Eventually, in 1948, he organized a study group including: Ing. Felipe Reca, Sr. Francisco von Proschek, Sr. Carlos Krotsch, Sr. Juan Lazlo, Ing. Jose Ovidio Martinez, Ing. Rodolfo Martinez de Vedia, Sr. Juan Landajo, Sra. Herminia Balado, and Sr. Arturo Loeffler.

Asociacion Argentina Interplanetaria President and astronautics pioneer PROFESSOR TEOFILO M. TABANERA., well-known IAF personality.

Austrian-born von Proschek has been an electrical engineering specialist with the Buenos Aires branch of the Siemens-Halske, AG, for twenty-five years. Krotsch and Lazlo are both of Austrian descent. They are electrical engineers each with more than 20 years experience with the Siemens organization. Martinez has a mechanical and electrical engineering background and is a consultant for the petroleum industry and is president of the South American Petroleum Institute. Martinez de Vedia has been a professor of mechanical engineering at La Plata University for nearly twenty years.

Also included in AAI membership are: Dr. Otto Waltz and Ing. Ricardo V. Dyrgalla. The latter, a current AAI director, who received his science degree from the University of Danzig before the war, served as an RAF fighter pilot and later as scientific officer at the RAE, finally emigrating to Argentina in 1947. In 1948 he designed and tested the first Argentina liquid propellant rocket motor. Dr. Otto Waltz, a former German, at one time designed V-2 fuel pumps for H. Walther at Kiel. Near the end of the war he developed rockets at the Schmidding works. He is now technical advisor to the D.G.N.F.M. (General Bureau of Military Production).

The Sociedad Argentina Interplanetaria was officially established in 1951, later changing to the present title.

Growth of the AAI passed the 600 membership mark in 1956. About one-third are professional people, university graduates; one-third, technicians and specialists; and one-third, university and technical students. It is interesting that the U.S. Earth Satellite Program has had little effect upon the rate of growth. The battle for acceptance of astronautics as a legitimate science had already been won in Argentina.

German Scientists Help

Of no small help were the dozens of German scientists and engineers who emigrated to Argentina after World War II. Some of these men had played a part in World War II German rocket developments. Many are now employed by the Argentine aeronautical industry and the Institute of Scientific Research of the Armed Forces.

AAI activities during the past few years have been varied. In Argentina defense requirements rocket research are small. Interest in astronautics is, therefore, self-generated.

Papers have been presented on subjects ranging from "sounding rocket research," "electronics requirements of rockets," "interplanetary navigation" and "uses of plastics in astronautics" to "legal aspects of artificial satellites" and "space medical research." Dr. Aldo Armando Cocca, recently a delegate to the Legal Committee, ICAO meeting in Montreal, is one of the small group of lawyers who have in recent years given careful consideration to "space law."

-the heat's off!

This Electronic Reliability Engineer just discovered the IERC way to insure his chances of meeting equipment reliability specifications and military acceptance schedules.

Tubes failures (too often and too soon) caused by heat and vibration, *the major causes of electron tube failures,* were his problem.

With IERC Heat-dissipating Tube Shields, the "heat was off" *both* the suffering tubes and our man with the problem! Tube operating temperatures were lowered as much as 150°C and tubes are lasting 5 times longer. Schedules were met—time and money saved—highest tube reliability achieved!

Suspect and investigate the heat and vibration menace when tube failures plague you. Eliminate it with IERC Heat-dissipating Tube Shields —available in sizes for Miniature, Subminiature, Octal and Power types of electron tubes.

PATENTED OR PATS PEND. IERC T-12 SHIELD AND BASE WITH 6080 TUBE ILLUSTRATED.
CROSS-LICENSED WITH NORTH AMERICAN AVIATION, INC.

THERMAL CONDITIONING OF ROCKETS AND GUIDED MISSILES

HEATING OPTICAL, ELECTRONIC, OR HYDRAULIC AIRBORNE EQUIPMENT

WHERE CAN YOU USE G-E SPECIALTY HEATING EQUIPMENT?

Whenever your equipment requires thermal conditioning, General Electric specialty heating equipment can help.

G.E. has had extensive design and manufacturing experience in providing controlled heating for a wide variety of applications. These applications range from giant guided missile blankets to tiny one-inch-long accelerometer heaters. Problems of intricate shape, large or small size, unusual environmental conditions, and amount of heat required have all been solved.

LET US ANALYSE YOUR HEATING PROBLEM; a General Electric specialty heating expert is available and a prompt answer is assured.

FOR MORE INFORMATION contact your General Electric Aviation and Defense Industries Sales Office or send coupon.

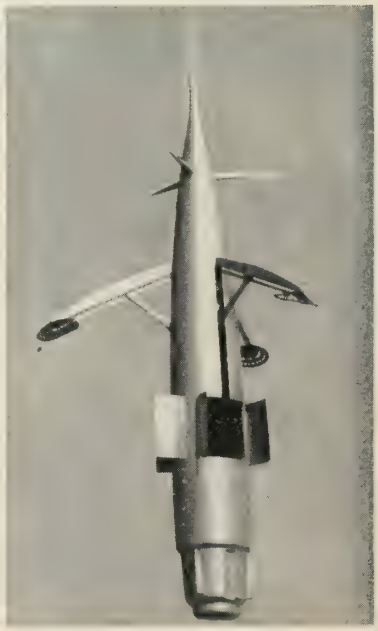
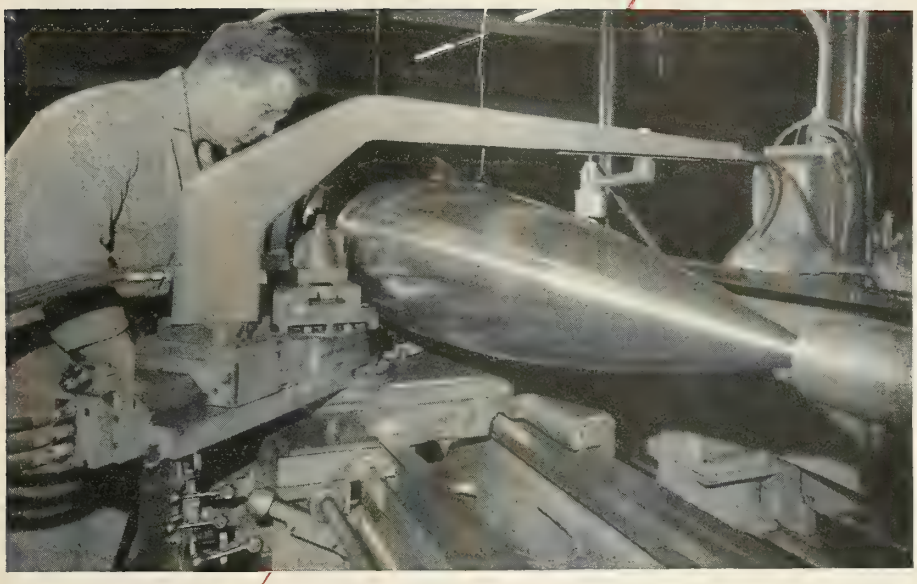
GENERAL ELECTRIC



The works of Drs. H. J. A. von Beckh and Heinz von Diringshofen of the National Institute of Aeronautical Medicine in Buenos Aires have been reported in the Journal of Aviation Medicine in the U.S. Papers by Cocca, von Beckh have been presented in behalf of the AAI at the annual congresses of the International Astronautical Federation in Europe.

The AAI has conducted two six-month astronautics courses, basic and advanced, for the past two years. Under the direction of Dr. Otto Waltz and Ing. Ricardo Dyrgalla a small group of younger members of the AAI have calculated, designed and constructed a liquid propellant micro-rocket motor.



In October 1955 the AAI held an exhibition which drew an attendance of more than 80,000 in its twenty days' run. Exhibits of models, photographs, charts explaining astronautics and the AAI micro-rocket set-up were displayed. Plans have now been made with the Argentine Government to set up an AAI-administered planetarium.

A 36-page review of activities and short articles is published quarterly. An astronautical library is maintained at secretarial headquarters. From time to time the AAI holds special meetings or social functions. An example of these was the overnight trip to the I.A.M.E. factory and the reaction motor proving grounds at Jose de la Quintana, Cordoba.

The AAI played a significant role in stimulating interest which resulted in the establishment of the Astronautics

This conception of an earth satellite was on display at the October 1955 AAI exhibition in Argentina which drew an attendance of 80,000. Note the arrangement of antennae.

MISSILE METAL MACHINING

. . . a guided missile component being machined at Diversey Engineering. Another of the many missile hardware parts involving intricate and difficult machining techniques. Diversey Engineering makes these and many other missile and jet hardware parts. Some of these parts are midsections, accumulators, bulkheads, rings, cones, and nozzles.

Have your work done at Diversey Engineering by skilled machinists who use the finest and newest equipment, one of which is the very latest 48″ Monarch Air Gage Tracer Lathe. Nowhere else can you get such extensive facilities and experienced machinists for contour machining of Titanium, Inconel, A-286, Haynes Stellite, and Zirconium.

Write or phone for information regarding your designs and blueprints.

Center at the National University of Cuyo, Mendoza. Founded in 1953 by the Rector of the University, Dr. I. Fernando Cruz, in the Department of Scientific Research, it is believed that this was the first formal recognition of astronautics by a university. Directorship of the Astronautics Center was offered originally to Austrian-born Dr. Ing. Eugen Säenger and his wife Dr. Irene Säenger-Bredt.

The Säengers, widely known in rocket and astronautical circles, were at this time working for the French defense department near Paris. Säenger was formerly director of the German Luftwaffe rocket center at Trauen. Known especially for his technical works including *Raketenflugtechnik*, Säenger and his mathematician wife developed the preliminary design study for the globe-circling rocket bomber.

Unfortunately for the Institute, difficulties prevented the travel of the Säengers to Argentina. The first director was the well known Dr. Ing. Walter Georgii, a close friend of the Säengers.

When Dr. Georgii took over the directorship of the Astronautics Center there were five other Argentine academic institutions with astronautics research interests. They were: Institute of Nuclear Physics, Aerophysics Institute, Mathematics Center, Faculty of Medical Science Tomas Peron, all in Mendoza; and Astronomical Observatory Felix Aquilar, in San Juan.

Professor Georgii's efforts were directed towards a program of upper atmosphere research consisting of a sounding rocket program limited to a modest 60 km. The sudden death in 1954 of the founder, Dean Cruz, and the subsequent departure of Dr. Georgii from Argentina has resulted in the activities of the Astronautics Center virtually ceasing for the moment.

Further IGY activities of AAI include: translation of the MOONWATCH Bulletins for distribution to Spanish-speaking astronomers and IAF Member Societies. This assistance was welcomed. The MOONWATCH Bulletins are published by the Smithsonian Astrophysical Observatory, Cambridge, Mass., for the guidance of trackers.

Early in January Dr. J. Allen Hynek, Associate Director of the Smithsonian Observatory will meet with Tabanera in Buenos Aires to discuss progress. Professor Hynek, of the Ohio State University astronomy department, is on leave to aid Professor Whipple in the IGY optical tracking program.

The AAI is cooperating with the Asociacion Amigos de la Astronomia in organizing volunteer tracking teams. It is expected that at least three groups will be established in Argentina—in Buenos Aires, Rosario and Cordoba ★

International Scene

By Anthony Vandyk

Low price was the prime reason why Japan ordered 200 *Airone* proximity-fused rockets from an Italian company, Polverifici Stacchini of Rome. The *Airone* uses solid fuel and is reported to have a range of 6,500 ft. The Japanese Air Force will test fire the *Airone* rockets from F-86F fighters. Polverifici Stacchini is working on a guided version of the *Airone* to be submitted to the Italian Air Force for evaluation.

•

Vickers-Armstrongs' air-to-air missile has been cancelled by the British government and, as a consequence, the British firm's Australian subsidiary has scheduled the closing down of its guided weapons division. The cancellation was decided because the missile was deemed too complicated and ambitious. Another company is to supply a cheaper and less complex weapon in place of the VA missile.

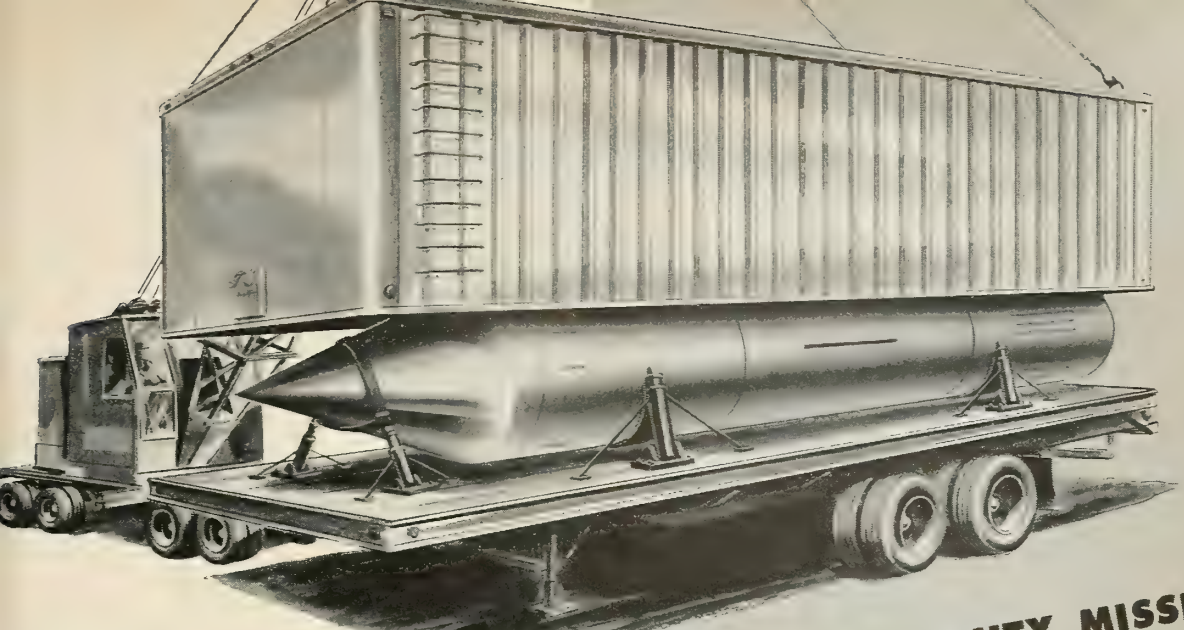
•

On the lonely rocky Mediterranean island of Sardinia Whitehead-Motofides has been testing its new *A.R.15* liquid-fuel auto-feed rocket. The Italian company, with its headquarters in Leghorn, is understood to have developed the *A.R.15* as an intermediate test vehicle as part of a program to develop a larger, fully guided ground-to-air missile.

•

"Fissile Missile" is the nickname used in the British press for the ICBM with H-bomb warhead under development by the British industry. Main headquarters for work on the British ICBM are at the Royal Aircraft Establishment. The work is under the direction of the Ministry of Supply's Ballistic Missile Division which is headed by 40-year-old Denis Lyons.

•



Many European companies are performing research work in the missile field under USAF contracts. One such contract has been awarded to Italy's Centro Italiano per la Propulsione a Reazione, located in Turin. It is understood that the Centro has been asked to develop a missile in the *Sidewinder* category with infra-red guidance.

•

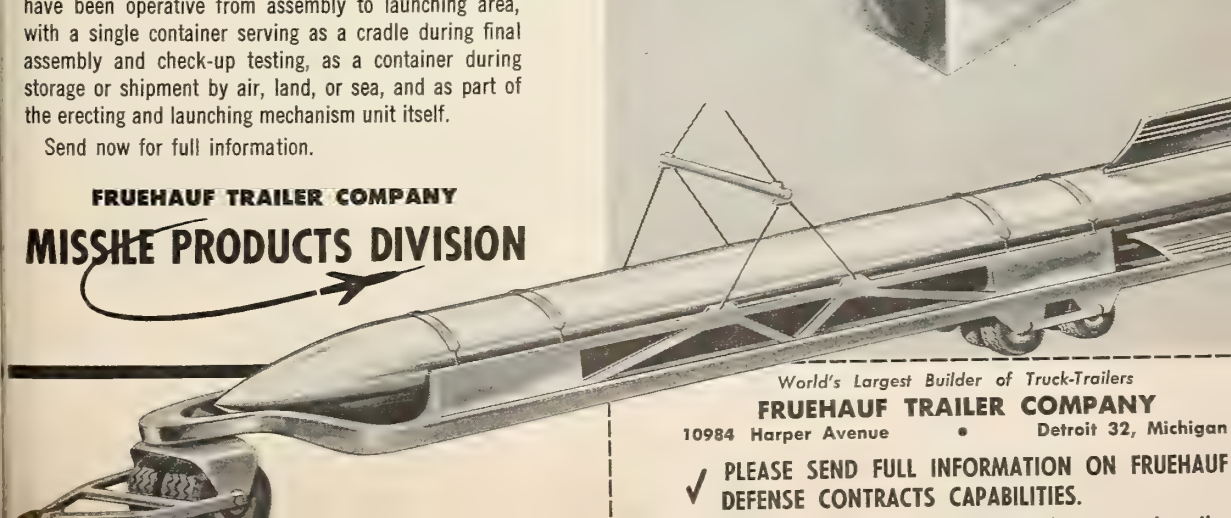
It seems that it may be some long time before Fairey Aviation will be able to mention anything other than the air-to-air *Fireflash* in discussing its missile activities. Board Chairman Roland T. Oulton recently told stockholders that the new projects under way in the firm's Guided Weapons Division are "of long-term nature, due to their complexity." He reported that interest has been shown in the *Fireflash* by NATO countries.

•

The French Navy is becoming very missile conscious. Its 1957 budget provides for the conversion of the transport, Ile d'Oleron, into an experimental missile-launching ship. The 1958 budget will include a 5,000-ton missile-equipped cruiser as well as a 30,000-ton aircraft carrier. The French Navy is putting a lot of faith, and money, inte the Breguet 1050 Dart-powered anti-submarine aircraft which is equipped with missiles. Fifty have been ordered under the 1956 budget, 25 in 1957 and a further 25 in 1958.

EVELOPING CONTAINERS FOR AMERICA'S MIGHTY MISSILE

Consult Fruehauf's Experienced Engineering And Production Staff With Any Problem In Missiles Handling Equipment



Whether your problem concerns weapons as large as the famed Redstone or as small as the air-to-air Falcon, Fruehauf has expert, experienced engineering and production help to offer in the packaging and handling of the units. This experience includes many different types of packaging and cradling units, including the channel-shaped pallet type and the conventional rectangular box type. Facilities at Fruehauf's 14 plants are ideally adapted to the manufacture of steel, aluminum, or stainless steel containers and thermo-insulated containers as well.

Containers developed to date with Fruehauf assistance have been operative from assembly to launching area, with a single container serving as a cradle during final assembly and check-up testing, as a container during storage or shipment by air, land, or sea, and as part of the erecting and launching mechanism unit itself.

INDUSTRY SPOTLIGHT

By Joseph S. Murphy

NICKEL FORECAST:

Four More Years of Shortage

Recent decision by The International Nickel Co. of Canada to boost its annual nickel output by some 65,000 tons starting in 1960 should prove welcome news to aircraft, missile and rocket builders.

But before this new found supply becomes a reality, industry can look to a continuing shortage, possibly lasting through 1960, according to market consultant Henry D. Lytton.

Demands for nickel-bearing stainless steels and jet engine super-alloys continued unabated throughout 1956. Future needs for these same metals, plus those of K-Monel and nickel-cobalt alloys being developed to beat the heat problem in supersonic aircraft and missiles, have introduced an unknown quantity into the nickel supply picture.

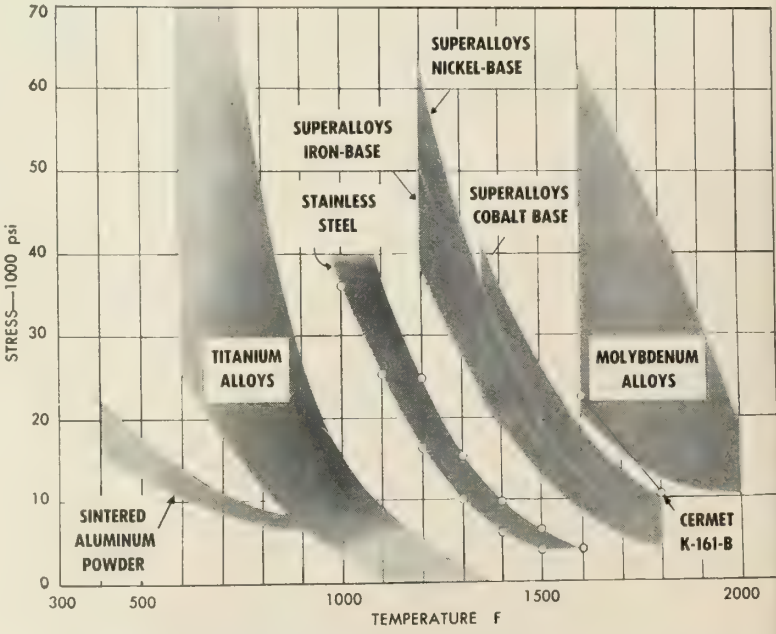
According to the Lytton report, the true nickel shortage last year was larger than apparent in consumption trends. As a result, stainless steel scrap prices, particularly those of nickel-bearing 18-8 stainless, rode the crest of the shortage and soared as much as 45% between January and the year end.

If 1956 supplies had been adequate, the former government metals specialist adds, steel production alone could have used more than 77,000 tons of newly-mined nickel in meeting present demands and regaining all markets lost during the past 10 years of intermittent shortages. Another 88,000 tons usable by industry pegged the 1956 need at 165,000 tons, before allowances for any government stockpiling.

Against this need stood a late-year Commerce Dept. forecast of 150,000 tons supply in 1956 and 162,500 tons this year.

And just how influential aircraft and missile industry needs may be in shaping the future nickel supply situation is borne out in Lytton's analysis of 1965 demands.

Steel industry, he estimates, will require an additional 12,000 tons and non-steel nickel markets another 10,500 tons, placing minimum 1965 demands 22,500 tons above the 165,000 tons that could have been used in 1956.



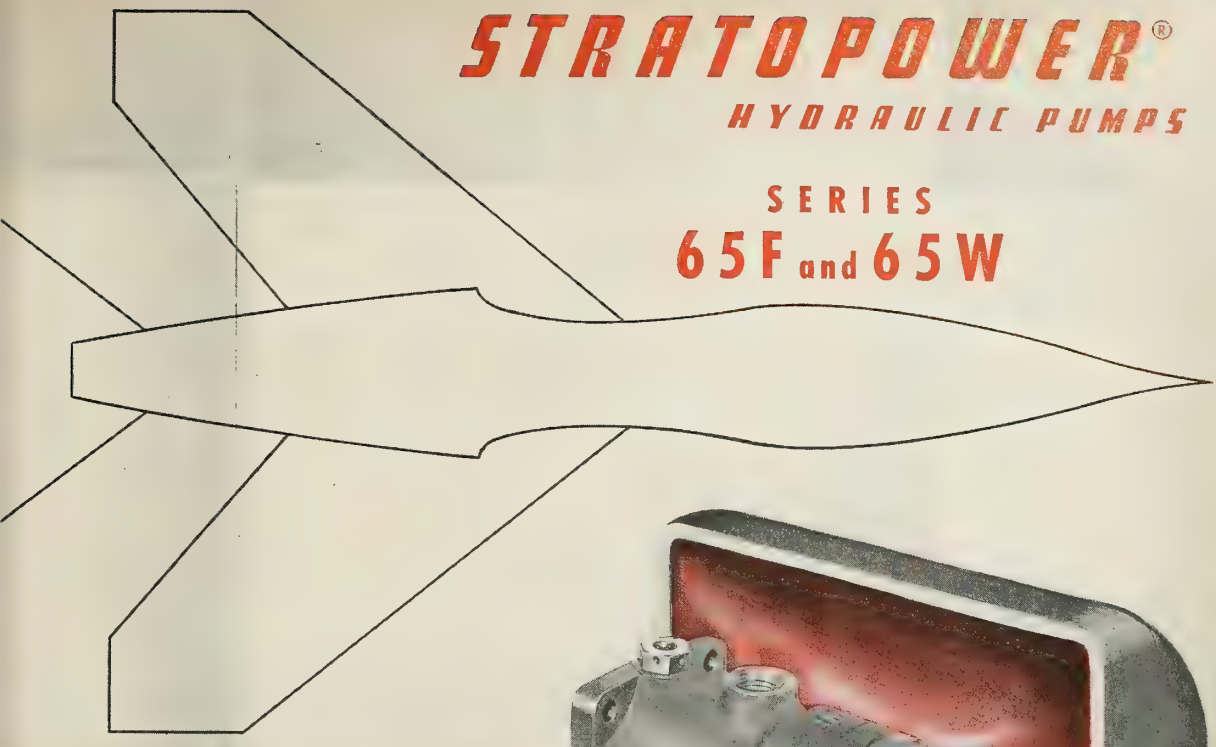
However, the analysis took into account present-day needs of some 12,000 tons of nickel in super-alloy stainless steels for jet engines, but made no provision for expanded civil and military jet needs or those for supersonic and hypersonic aircraft and missile.

Assuming that the first-half 1956 rate of jet engine super-alloy production were to increase four-fold in the next 10 years, says Lytton, total demand for nickel immediately would approximate Office of Defense Mobilization's 220,000-ton goal.

On the world-wide nickel production scene, according to Inco president Henry S. Wingate, the company's plan for increased production coupled with that of other industry sources should bring 1960 nickel output between 300,000 and 312,500 tons. This would represent a jump of about 82,500 to 100,000 tons over 1955's total output of 213,500.

Inco's expansion, involving two new mines in the Mystery-Moak Lakes area of Northern Manitoba, is a $175,000,000 project. When in operation, it will constitute the second largest nickel-producing operation in the world—the largest being the company's present operation in the Sudbury District of Ontario, Canada.

The Manitoba activity, plus programmed output from Sudbury, will raise Inco's 1955 nickel production about 50%, or by approximately 130,000,000 pounds to 385,000,000 pounds. Of this, some 24,000,000 pounds will be regular production to replace present temporary premium-priced production for the U.S. government stockpile, and



Key role of nickel in development of high speed aircraft and missile structures is evident in these 1,000-hr. stress vs. temperature curves. It extends from present use in nickel-bearing stainless, through the nickel cobalt group.

the balance of 106,000,000 will represent at net increase in total capacity for industry consumption.

The Lytton report, issued prior to the Inco decision, traces nickel consumption over the past 45 years and forecasts demands over the next ten years. Copies of the 81-page document along with a 20-page analysis of 1956 nickel demand are available from Henry D. Lytton, 1326 27th St., Washington 7, D.C., at $10.00.

North American Aviation Surveys Midwest

North American Aviation's Rocketdyne division is making a detailed survey in midwestern states to determine new vendor sources for its Neosho, Mo. plant. H. H. Vaughn, superintendent of manufacturing; R. L. Radford, supervisor of purchasing, outside production, and N. G. Irvin, inspection, form a team currently visiting vendor sources checking capabilities of vendors to produce the intricate valves required at Neosho. Initial valve requirements have been placed with present Rocketdyne suppliers in California. Several other vendor surveys are just now being gotten under way.

Renegotiation Decisions Hit Three Missile Firms

Douglas Aircraft Co. in December became the third major aircraft and missile producer to be judged on the receiving end of excess profits.

The Southern California regional Renegotiation Board recommended that profits of the *Nike* and *Honest John* producer be ruled excessive in the gross amount of $9 million for fiscal year 1953. If upheld by the Renegotiation Board in Washington, this would indicate a possible net refund to the government of $2,240,000.

Company president Donald W. Douglas said the company was not yet informed fully of the basis for the regional recommendation, but maintained that proper consideration of all facts would show its profits were not excessive.

In November, North American Aviation, Inc. was notified by a regional board that its 1953 profits were considered excessive in the amount of $6 million. Allowance for state and federal taxes for this amount would entail a refund of $1.3 million, if upheld.

The third producer, Boeing Airplane Co., is still contesting a decision of the Renegotiation Board that its 1952 profits were $10 million in excess. Boeing comptroller Clyde Skeen, in a recent address, urged that Congress undertake a comprehensive review of current administration of the Renegotiation Act.

Skeen contended that the trend of present administration of the statutory Renegotiation Board, if it continues, will destroy industry incentive and result in less defense per dollar. He noted that if it is Congress' intent to arbitrarily restrict profits, this can be accomplished much more simply than by the complex, time-consuming and expensive process of renegotiation.

Titanium Production Up Sharply This Year

Production of mill products by the titanium industry almost tripled its 1955 volume last year and will more than double its 1956 output this year, according to T. W. Lippert, Titanium Metals Corp. of America.

The TMC sales manager estimates output of finished mill shapes totaled 10.6 million lbs. in 1956 compared to

AN UNUSUAL BUY!
SATELLITE TELESCOPE

Edmund Scientific Co. was consulted by the coordinator of Visual Satellite Observations of the Smithsonian Astro-Physical Observatory regarding development of an optical instrument to meet the unique requirements of MOONWATCH. Needed was a low-cost instrument of greatest possible field—with the ability to observe faint objects with only slight magnification. Result—our Edscorp Satellite Telescope! Features: Wide (51mm) diameter, low reflection coated objective lens. 6 elements, extremely wide field, coated Erfle Eyepiece which, in combination with the objective, gives 5.5 power with a big 12 degree field and over 7mm exit pupil.

OTHER USES FOR THE SATELLITE SCOPE

Makes a perfect wide field finder. Makes a wonderful Comet seeker. Makes a fine Richest-Field telescope.

Model GLH

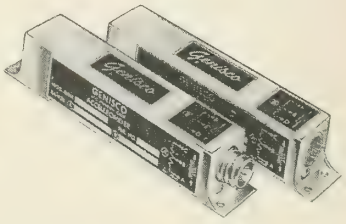
A rugged magnetically damped instrument with low natural frequencies for low range. High-quantity production assures good price and delivery schedules. Available in ranges from ±1 G to ±30 G.

Model DDL

Magnetically damped low-range instrument available in ranges from ±1 G to ±30 G. Ultra-sensitive models supplied as low as ±0.1 G. Certified to MIL-E-5400 and MIL-E-5272A. Especially good in severe shock and vibration applications. An acceleration-sensitive switch version of the DDL is designated as the Model DDS.

Model GAL

Incorporates a variable transformer a-c output with the magnetically damped sensory mechanism of the proven Models DDL and GLH. Superior reliability, life, resolution, and sensitivity. Available in ranges from ±1 G to ±30 G. Range as low as ±0.1 G also obtainable.



Model GMO

A rugged, miniature, viscous-damped instrument with ranges from ±2 G to ±30 G. Unbalanced-range instruments also available. Medium high natural frequencies.

Model GMT

Basically a Model GMO with internal thermostat-operated heater, assuring maximum environmental stability within the instrument. Damping remains constant with change in ambient temperature.

Model GDM

Miniature double-potentiometer instrument capable of sensing lateral acceleration in two mutually perpendicular planes (e.g., pitch and yaw). Ideally suited for missile and high-speed aircraft flight control systems.

NEW! GENISCO ACCELEROMETERS NOW GOLD PLATED FOR GREATER RELIABILITY

CASES GOLD PLATED INSIDE AND OUT—This new trend in instrument plating has two important advantages over tin plating or fusing. Being the least active metal, gold prevents the formation of crystalline "whiskers" inside the case which could reduce performance and even cause malfunction. Gold plating also assures positive protection against corrosion to the exterior of the case and, because of its excellent solderability, makes possible a more reliable hermetic seal. The new gold plating is available on *all* models at *no extra cost.*

Descriptive data sheets available on all models.

3.8 million in 1955. This year the figure will rise to about 23 million pounds, he said.

Meanwhile, titanium sponge dropped in cost to $2.75 a pound from $3.45 a year ago and $5.00 in 1954.

Convair Gets $29 Million Contract for *Terrier*

Navy has awarded Convair-Pomona division a $29 million contract to produce guidance and control units for *Terrier* missiles. The Navy also confirmed that Convair has entered production with a new version of the antiaircraft missile.

The improved *Terrier* entered production September 1, about two months before phase-out of the original version. The new *Terrier* is basically the same missile with revised engineering features to increase its producibility.

The Convair supersonic surface-to-air missile is now fitted on the cruisers *Canberra* and *Boston* as well as the destroyer *Gyatt*. According to Bureau of Ordnance chief RAdm. F. S. Withington, Navy plans its use on many other destroyer vessel types.

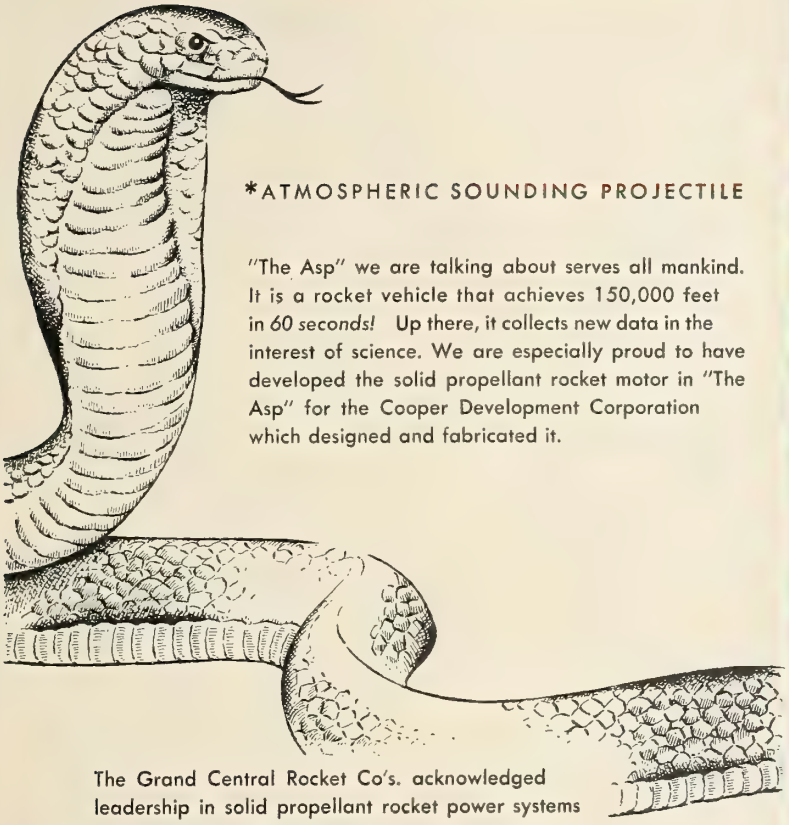
Martin Sees $300 Million In Sales for 1956

Final sales figure at The Glenn L. Martin Co. for the year 1956 is expected to top $300 million, up more than 8% from $272 million in 1955, according to Martin secretary-treasurer W. L. Lucas.

The Baltimore firm, engaged in three major missile projects (*Matador, Lacrosse* and *Titan*) plus the *Vanguard* satellite, also experienced an increase over its backlog of $660 million a year ago.

Missile business at Martin is now almost equal its total volume in aircraft contracts, with the combined missile and aircraft orders representing about 90% of its backlog.

AF to Spend $25 Million For ICBM Training Center

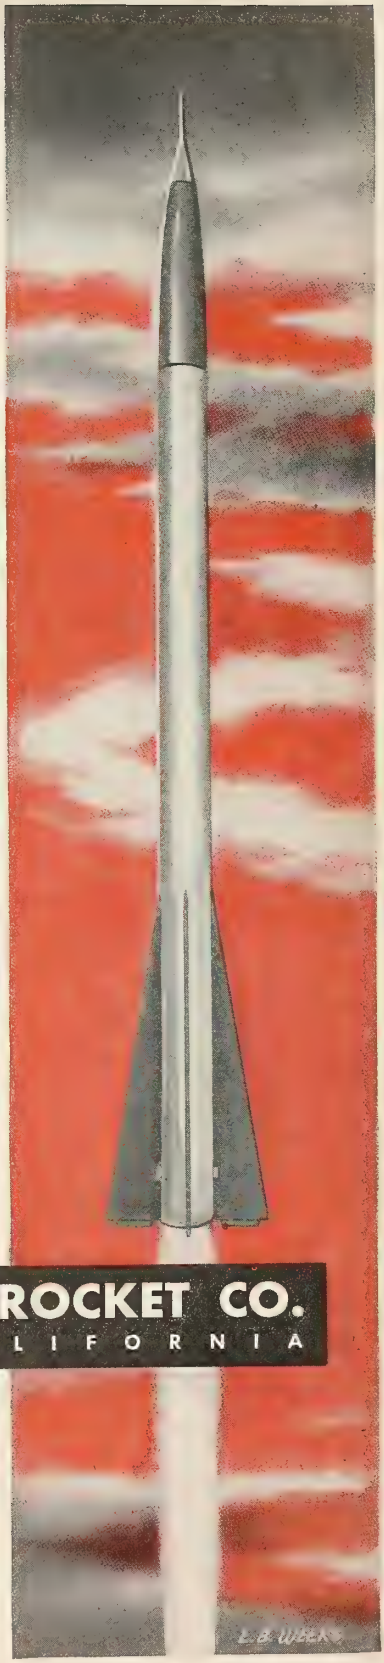


USAF plans to spend about $25 million this fiscal year to modernize and enlarge its first ballistic missile training center, according to Maj. Gen. B. A. Schriever, Western Development Division commander.

With top-level Defense Dept. approval, USAF has taken over Army's Camp Cooke at Lampoc, Calif. and expects the center to be fully operational in about six months.

Design contract to draw up plans has been awarded to Holmes and Narver, Los Angeles architects.

The ASP*



can be friendly!

*ATMOSPHERIC SOUNDING PROJECTILE

"The Asp" we are talking about serves all mankind. It is a rocket vehicle that achieves 150,000 feet in *60 seconds!* Up there, it collects new data in the interest of science. We are especially proud to have developed the solid propellant rocket motor in "The Asp" for the Cooper Development Corporation which designed and fabricated it.

The Grand Central Rocket Co's. acknowledged leadership in solid propellant rocket power systems has attracted the finest engineers. We invite you to join our team.

To Leslie Van Dusen, Personnel Manager.

Navy Reorders *Regulus*, Boosts Chance Vought Backlog by $26 Million

New Navy orders for *Regulus I* and *Regulus II* missiles amounting to $26 million have hiked total backlog for that service with Chance Vought Aircraft to more than $500 million.

It marked Navy's second order for *Regulus II, a* previous $12 million contract coming in July 1956. Navy also confirmed that the new *Regulus* is supersonic, although no further details were released.

Regulus II is fitted with Wright J65 on first eight pre-production models, but will use General Electric J79 in remainder. *Regulus I,* which is subsonic, is powered by Allison J33.

Bomarc Mass Order Believed Near

An Air Force order for large quantity production of the supersonic ramjet-powered Boeing *Bomarc* missile is expected this month. The AF move is anticipated in the light of successful firings against B-17 drones at Patrick AFB Missile Test Center following several months of advanced testing.

Also pointing to an early order was the increased activity at Boeing in recent months to select a final site for *Bomarc* production. On November 7 the Seattle firm took option on the Ford Motor Co. plant at Richmond, Calif. and only a month later optioned additional land in San Ramon Valley near Parks AFB.

Although neither option has been exercised, Boeing plan is to establish the new facility as an integrated pilotless interceptor production and assembly plant should the site be selected.

Aerojet Sales Increase 100% Over 1955

Total 1956 sales of Aerojet-General Corp., subsidiary of General Tire & Rubber Co., are expected to reach $140 million, up 100% over 1955, company officials estimate. However, net profit after taxes will rise only 50% over last year as the result of increased activity in cost-plus type development contracts.

Sharp increase in sales was credited to Defense awards to Aerojet's liquid rocket plant at Sacramento, Calif. An even sharper rise in sales is predicted for 1957 resulting from development of the AGN 201 nucleonic reactor by Aerojet's new subsidiary, Aerojet-General Nucleonics Corp.

Industry Highlights

By Fred S. Hunter

Grand Central Rocket Co. is preparing to set up a new rocket engine test facility at a remote location about 15 miles from its Redlands plant. Grand Central picked this particular 1000-acre site because it is part of a large holding originally acquired under a Spanish land grant and still intact. The owners agreed to maintain a two mile buffer zone as a provision of the lease.

The new unit will supplement a six-stand test facility Grand Central now operates in the foothills back of the Redlands plant. Structurally, one of these stands can test rocket engines up to 1,000,000 pounds thrust and two others 500,000 pounds. But Grand Central's plans not to exceed the 100,000-pound thrust level in any firings at the factory site but to go to the country with bigger stuff. Grand Central is on good terms with the folk around Redlands and aims to stay that way.

●

Having phased out on production on the Sperry *Sparrow I,* Douglas now has the *Sparrow III,* on which it is the prime contractor, but this version of the Navy air-to-air missile has not been ordered into production. The Douglas contribution to the Raytheon *Sparrow II* was strictly R and D. It developed the missile airframe, but is not participating in its production. *Sparrow III* guidance is Bendix Pacific.

●

Dan Kimball, president of Aerojet-General Corp., would appreciate it if the government would establish a post office named Aerojet at the location of the company's growing rocket engine plant 15 miles east of Sacramento. There is nothing in the area except the Aerojet people now that the gold dredgers have gone their way, so why not a post office named Aerojet, Cailfornia? We wish Dan luck, but we dunno. Dan is an active Democrat and the post office department is in Republican hands right now.

●

If you can run a lathe or a typewriter, every employment office door in town will swing wide open for you. Next to engineers, most critical personnel shortage on the coast is machinists. Then secretaries. A sign of the times is to note how the proportion of help wanted advertising for missile people keeps growing in the classified columns of the Los Angeles papers. Another sign—one employment agency advertises it has openings paying up to $30,000 a year. And then there's North American Aviation's scheme to solve part of its problem with "week-end" jobs. Example—it hires key punch operators for Saturday work only.

●

Hughes Aircraft, a leader in this work, has 1500 physically handicapped employes at its Tucson plant . . . Everybody was happy to see Lockheed reward Herschel Brown with permanent appointment as assistant general manager of the Missile Systems division . . . The Douglas *Rockaire* sounding rocket is designed for launching from a fighter plane at altitude . . . North American's Rocketdyne division has four Ipsen heat treat furnaces capable of operating up to 2100° F . . . George P. Sutton, an engineering section chief at Rocketdyne and recently elected v.p. of the American Rocket Society, has published a second edition of his book, *Rocket Propulsion Elements,* including much new material.

●

We note that Mauna Loa on the island of Hawaii is one of the 12 official earth satellite tracking stations. Selection of this site, no doubt, was made because of the excellent visibility prevailing in the islands. And what a delightful way to make a lasting contribution to the progress of science, sitting under a palm tree, tracking a missile with one eye and a hula dancer with the other.

Computer Conference Scheduled in New York

Conference on digital computing in the aircraft industry, including techniques used in structural analysis of aircraft and missiles, is being sponsored by New York University January 31 and February 1.

Entire program will be devoted to aircraft industry computer activities with some 25 papers slated for presentation. Write Dr. M. A. Woodbury, NYU College of Engineering, University Heights 53, N.Y. for arrangements.

Link to Open West Coast Facility

Link Aviation, Inc. this month will begin operations in a new research facility at Palo Alto, Calif. intended to permit closer coordination with west coast missile producers.

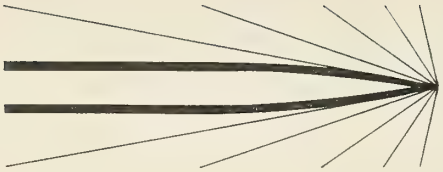
New laboratory will be situated at 430 University Ave., Palo Alto, and is expected to have an initial staff of 75 employes. Negotiations are also underway for further expansion in Stanford University's Industrial Park.

Link's west coast activities will include work in advanced electronic computer systems, transistor circuits and missile test systems.

NAA Pays $384,000 In C/L Adjustment

Employes of North American Aviation received a 3.2% cost-of-living pay increase effective December 17, adding an estimated $384,000 monthly to NAA's payroll.

Increase affects employes at five company facilities in Los Angeles, plus divisions at Fresno, Calif.; Columbus, Ohio; Neosho, Mo. and Cocoa, Fla.



Douglas, NAA Receive Missile/Rocket Contracts

Air Materiel Command has awarded Douglas Aircraft Co., Santa Monica division a $3,650,622 contract for rockets, spare parts and data.

North American Aviation, Inc. received a $2,833,000 award covering new facilities for its guided missile (*Navaho*) program.

Sperry Facility Underway

Newly formed Sperry Phoenix Co. has begun construction of a $3 million, 81,000 sq. ft. plant in Phoenix, Ariz. with target for completion set in August. Company expects to employ about 500 persons in new plant.

MISSILE ENGINEERS

Many new positions are being created at Northrop Aircraft for missile engineers in a wide range of activity: control, guidance, servo, computers, recording, optical, reliability, electro-mechanical, telemetering and electronics. There's an interesting position for you, at your own experience level, with attractive remuneration and steady advancement, in one of the following groups:

GUIDANCE AND CONTROLS, encompassing research and development of advance automatic guidance and flight control systems for both missiles and piloted aircraft. Specific areas of development include: radio and radar systems, flight control systems, inertial guidance systems, instrument servo systems, digital computer and magnetic tape recording systems, airborne analogue computer systems, optical and mechanical systems, and systems test and analyzer equipment.

FLIGHT TEST ENGINEERING SECTION, which plans the missile test programs and establishes test data requirements in support of the programs. The data requirements are predicated on the test information required by the engineering analytical and design groups to develop and demonstrate the final missile design, and are the basis from which instrumentation requirements are formulated.

The analysis work performed consists of aerodynamic, missile systems, dynamics, flight control, propulsion and guidance evaluation. The Flight Test Engineering Section is also responsible for the field test program of the ground support equipment required for the missile.

FLIGHT TEST INSTRUMENTATION SECTION, which includes a Systems Engineering Group responsible for the system design concept; a Development Laboratory where electronic and electro-mechanical systems and components are developed; an Instrumentation Design Group for the detail design of test instrumentation components and systems; a Mechanic Laboratory where the instrumentation hardware is fabricated; and a Calibration and Test Group where the various instrumentation items and systems are calibrated and tested.

For 17 years Northrop Aircraft has pioneered in missile research and development. As a member of this forefront organization in this growing field, new opportunities for full expression of your initiative and ability will always be yours at Northrop.

If you qualify for any of these attractive positions, we invite you to contact the Manager of Engineering Industrial Relations, Northrop Aircraft, Inc., telephone ORegon 8-9111, Extension 1893, or write to: 1015 East Broadway, Department 4600-L, Hawthorne, California.

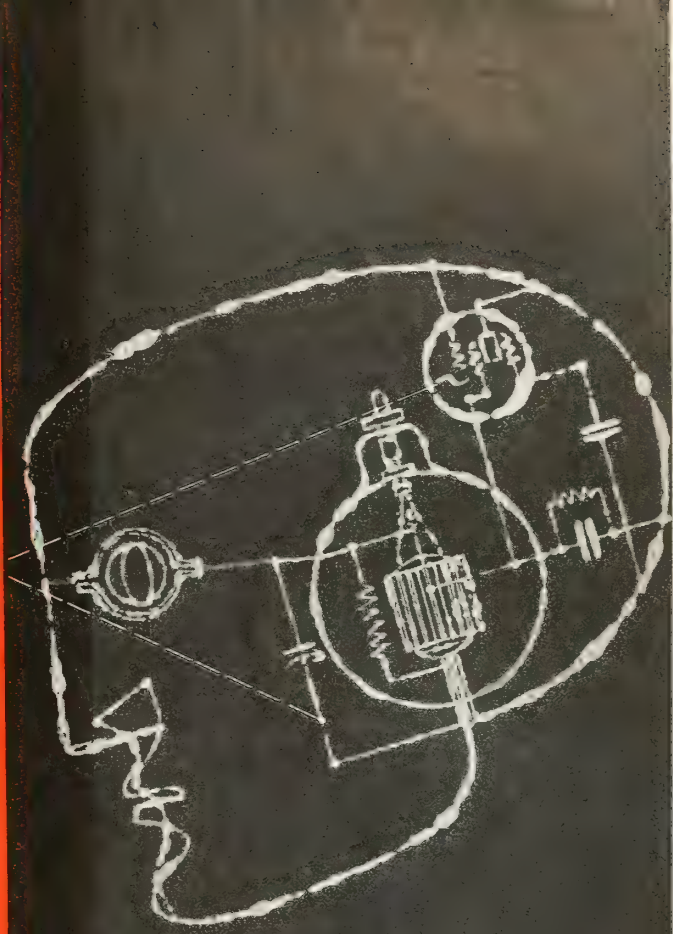
INDUSTRY BAROMETER

MISSILE VS. AIRCRAFT EXPENDITURES

(12 Month Moving Averages)

An examination of current Department of Defense expenditures for aircraft and guided missiles reveals that for every $5 spent on aircraft, the Government also disburses $1 on guided missiles and supporting equipment. A twelve-month moving average for the period ending September 30, 1956 shows DOD guided missile expenditures are now 19% of money spent for aircraft. As recently as January 1955 expenditures for missiles were only 5% of aircraft. The trend, shown in the accompanying charts, of spending a greater per cent of procurement money for missiles has been officially acknowledged by the Pentagon.



In September of 1956, Reuben Robertson, Jr., Deputy Defense Secretary, stated that the U.S. will spend well over $2.5 billion dollars on missile development and procurement in Fiscal 1957.

The position of the Air Force, as the largest missile procurer of the three services, is especially noteworthy. Col. W. A. Davis, Director, Procurement and Production, Deputy Chief of Staff, Materiel, made the following statement when he appeared before the House of Representatives Military Appropriations Subcommittee in March of '56.

". . . we are integrating missiles into our force structure as replacements for manned aircraft. The effect of these replacements will be minor at first but will grow progressively each year. In 1952, out of our total production money for aircraft and related equipment, only 4% was allocated for missiles. In our fiscal year 1955 buying program, we are applying 12% to missiles. By fiscal year 1959, we expect to use 35% of our production dollars for missiles."

While missile expenditures have increased tremendously in the past few years, the total spent for both aircraft and missiles has experienced relative stability. In January of 1955 a twelve month moving average showed the DOD spent approximately $729 millions for aircraft plus missiles. In June of 1955, the figure was $717 millions. Low point for the period January 1955 through September 1956 was March 1956, when $677 millions was spent. Since March 1956 expenditures have been on the rise. Based on latest Pentagon data (September 1956) aircraft and missile expenditures are at the $698 millions per month level. The year 1957 should find the DOD missile expenditures going well over $700 millions per month level.

HOW TO IMPROVE A MISSILE'S IQ

...'s guided missile is an amazingly sophisticated and ...gent instrument, capable of complex thought and ...e action. Tomorrow's must have an even higher IQ.

To improve a missile's intelligence, Fairchild Guided Missiles Division engineers and scientists have developed radical new concepts for guidance and control, transferring their intelligence into the missile's guidance center.

Through sound research, inventiveness and imagination, FGMD engineers and scientists continue to make great strides in all fields of missile development...putting *more brain-power* into *more missile power.*

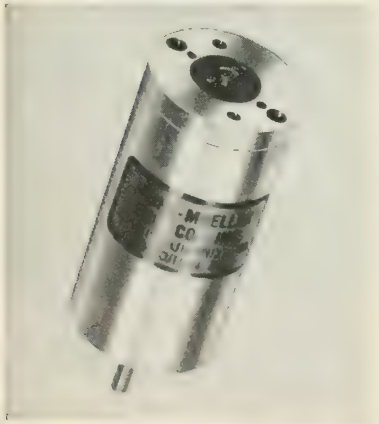
NEW MISSILE PRODUCTS

MISSILE TEST SET

A semi-automatic programmed test set for use in final testing of missile telemetering packages has been produced. Read-out is in digital form and the set is capable of programming about 200 different measurements.

According to the designers, the set electrically tests a 177-channel FM/FM missile telemetering system in less than an hour and can be operated by non-technical, semi-skilled personnel.



Only one operator is required to initiate the sequence of tests. Carrier frequency, power output, as well as frequency and amplitude of each sub-carrier channel are tested together with analysis of linearity sensitivity and frequency conversion.

A signal simulator rack provides simulated transducer signals. The read-out rack converts signals to digital form and this is printed on paper tape. Separate analysis of individual sub-carriers is permitted.

In addition to "Go No-Go" information, specific data is supplied. Bendix Pacific Division, 11600 Sherman Way, North Hollywood, Calif.

MINIATURE MOTORS

A series of new miniature d-c motors or generators measure only 1.625 in. long and 0.875 in. in diameter with a shaft diameter of 0.98 in.

Units feature self-aligning sleeve bearings with nylon retainers to assure quiet running. Shafts are hardened, ground and lapped and stators are Alnico TV ring type.

Motors include adjustable brush bracket for accurate speed of voltage output for clockwise or counter-clockwise rotation. Models with 1 in., 1.250 in. or 1.438 in. diameter are also available.

Heinz Mueller Engineering Co., 1906-08 N. Cicero Ave., Chicago 39, Ill.

SPRAY-ON CERAMIC

New Therm-O-Lab ceramic electrical heating elements developed for aircraft and missile use can be sprayed on surface to be coated and are rated to withstand Spec. MIL-E-5272A vibration tests.

The thin ceramic blanket is rated to perform dependably under operating temperatures up to 500°F. Therm-O-Lab Corp., 6940 Farmdale Ave., North Hollywood, Calif.

Circle No. 212 on Subscriber Service Card

FLUID SYSTEM FILTERS

"Rigimesh," a rigidized wire mesh used in filter elements for aircraft or missile hydraulic, oxygen, nitrogen and helium systems is designed for operating temperatures from —65° to 900°F. Produced by furnace welding the wires of the mesh at all contact points, Rigimesh is said to have working features that permit fabrication by cutting, rolling, corrugating and welding without losing uniformity of mesh openings.

According to its producer, filter elements have been adapted to operating pressures from vacuum to 10,000 psi and with particle size retention ratings from two to 2,000 microns. In one application, a Rigimesh laminate is used to line combustion chambers and afterburners of turbine engines so they can be transpiration cooled.

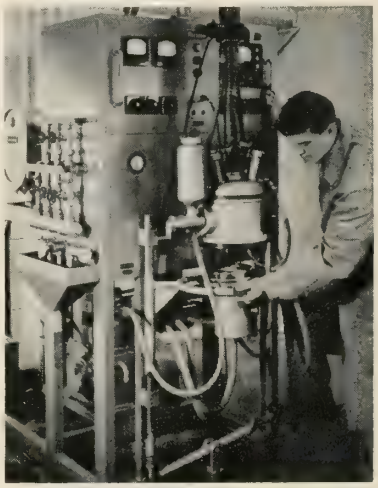
Aircraft Porous Media, Inc., c/o Pall Filtration Companies, 30 Sea Cliff Ave., Glen Cove, N. Y.

Circle No. 213 on Subscriber Service Card

MISSILE CABLE

Electronic cable with stable performance characteristics under temperature conditions ranging from —85° to 410°F has been announced. The manufacturer claims normal operation of the new cable under all present conditions of missile and rocket performance.

Teflon insulated conductors and a sheath of specially compounded silicone rubber have been used in a new design. Each conductor is free to move within certain limits and the entire cable core is allowed limited movement within the jacket.



A continuing automatic adjustment of these movements is claimed to allow flexing far beyond the limits of any other cable type over the stated temperature range: Conductors can be supplied in many color combinations for identification.

Douglas Roesch Division, Hall-Scott Inc., 2850 Seventh St., Berkeley, Calif.

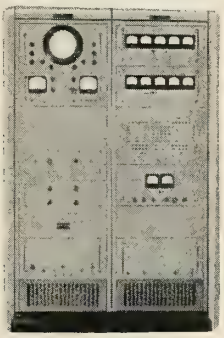
VACUUM ARC-MELTING FURNACE

A new laboratory arc-melting vacuum furnace that simulates conditions in a large production furnace is now available. The VA-L200C furnace is manufactured by W. C. Heraeus in West Germany and distributed in the U.S.



The furnace uses interchangeable consumable and non-consumable electrodes. It can handle high melting point metals such as nickel, iron copper and many metallic carbides and borides. Inert atmosphere or vacuum operation to 5 x 10 —4 mm hg is possible, and melts of a few ounces to several pounds can be handled.

The furnace has a water-cooled

Pulse Width Data Systems

THOMAS S. MEDEROS, JR., Sales Manager
Applied Science Corporation of Princeton
Princeton, New Jersey

A PW data system is a grouping of equipment which uses the techniques of time division multiplexing and Pulse Width coding to put a number of voltages representing physical quantities, into a form which permits transmission over a single circuit or link, or recording on a single channel or track. The system also provides for the separation and identification of the previously multiplexed data channels and decoding back into voltages, which are used to provide visual display, graphic records, input to data processing equipment or control functions.

M SERIES PW GROUND STATION

Separates and reduces all data channels in real time. Operates on signals from standard airborne set, FM/FM subcarrier, or magnetic tape recorder.

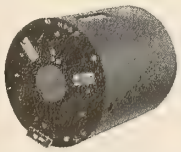
In a PW system, the intelligence is conveyed by the pulse duration rather than amplitude, and therefore the transmission medium is not required to have amplitude linearity but only the ability to discriminate between two states which may be called "on" and "off" or "mark" and "space."

Operation

The basic functional units required in any PW system are transducers, a commutator with suitable driving device, a keyer, an RF transmitter, and data reduction equipment for converting the PW data signals into usable form.

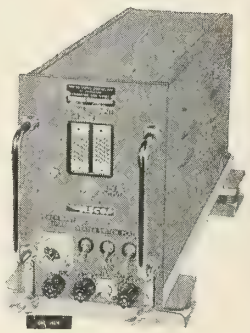
Since the PW data system requires that input signals should be in the form of voltages, suitable transducers capable of converting physical quantities into voltages are used. Present ASCOP PW multicoders operate from signals in the range of 0 to + 5 volts, and low-level equipment is now available with sufficient sensitivity to accommodate inputs in the low millivolt range.

The time division multiplexing is accomplished by a motor-driven rotary sampling switch or commutator. Standard sampling rate is 900 samples per sec, and commutators are now available for operation at 30 RPS over 30 points, 20 RPS over 45 points, and 10 RPS over 90 points. Since two points of the commutator in any of the systems are left unconnected, to provide a gap in the pulse train for "frame" identification, the existing numbers of channels available for data and references are 28, 43, and 88, respectively.



F SERIES MISSILE SETS

Samples up to 43 data sources. This rugged equipment is sealed and pressurized to withstand high altitudes, operation and temperature extremes.



System linearity is determined by the transfer characteristic of the keyer, from volts to Pulse Width, and the linearity of the translator back into volts. A typical ASCOP Pulse Width data system does not deviate from linearity between the scale end points, by more than 0.5 per cent. The total system drift, from any cause, is less than ±0.5 per cent of full scale. Since system levels are maintained by an automatic electronic servo, this degree of stability is maintained over periods of days or weeks, and is accomplished without any warm-up time.

With the stairstep type of electrical output provided by the M Series ground station, it is generally conceded that 6 samples per cycle of the highest data frequency component present allow visual interpolation of output records to better than 1% accuracy. This means that any channel of a 30 × 30 system can reproduce 5 cps data. The frequency response of one or more data channels in the system can be increased by a factor of 2, 3, 4, or more by increasing the effective sampling rate. This can be accomplished by applying the same transducer output to a corresponding numbers of commutator contacts, and making similar provision during decommutation.

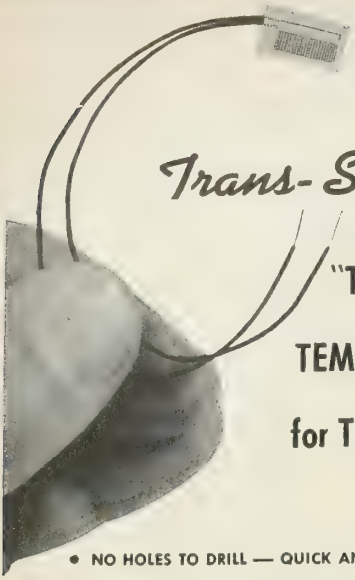
SPECIAL MISSILE SET

ASCOP-designed for a customer.

D SERIES PW MULTICODER

For aircraft, mobile or other applications where recovery or continued use is practical and where space and weight are not critical. Samples up to 43 data sources.

Uses



At present, most PW data systems are used for recording experimental test data from missiles and aircraft, where hazard, space limitation, and volume of data to be gathered make the use of a human observer impossible. Measurements of such quantities as the temperature, pressure, strain, altitude, acceleration, flow rate and position are made at rates thousands of times faster and much more accurate than could be done by visual observation and manual recording.

Additional application is also found in experimental test work where hazard and space are not limitations, but where the total volume of data require both high speed automatic measurement and recording. Engine test stands, reactors, and complex electronic equipment are typical devices whose testing requires the automatic measurement and recording of large numbers of physical properties.

PW data systems have been used where many measurements must be transmitted and displayed in easily interpreted form, as in the case where a pilot on the ground must rely on display instruments while he controls a drone aircraft, or in the case where the flight test engineers on the ground must observe conditions in a piloted aircraft in order to insure the safety of the pilot.

NEW

Trans-Sonics*

"TAPE-ON" SURFACE TEMPERATURE RESISTORS

for Temperature Telemetering

- NO HOLES TO DRILL — QUICK AND EASY "TAPE-ON" INSTALLATION
- OUTPUT UP TO 5 VOLTS WITHOUT AMPLIFICATION
- AVAILABLE IN VARIOUS RANGES FROM −300° to +400°F.
- RESISTANCE CHANGE OF 100 OHMS OVER SPECIFIED RANGE

Trans-Sonics Type 1371 "Tape-on" Surface Temperature Resistors are precision resistance thermometers with a platinum resistance winding as the sensing element. They may be applied to *any surface* whose temperatures are to be measured. In a commutation circuit, they modulate standard telemetering transmitters without amplification. The new Type 1371 "Tape-on" Surface Temperature Resistors may be added to an installation using other Trans-Sonics temperature transducers without any further circuitry modification. Each resistor is furnished with two 6" long fibreglas-covered constantan leads. Write for Bulletin 1370 to Trans-Sonics, Inc., Dept. 9.

what is grey matter worth?

For the engineer or scientist who has enough to make him different, *grey matter* is worth a rewarding life of creative achievement in a working climate where ideas are King...and the benefits measure up to the man and his mind.

For 56 years Firestone has grown on *grey matter*—in Research, Development and Production. Now, simply, we need additional *grey matter* for such Firestone "firsts" as the "Corporal" surface-to-surface ballistic missile. Here are just a few of the Engineering activities in which Firestone needs more *grey matter:*

Electronics Systems
Mechanical Systems
Propulsion Components
Flight Simulation
Mechanical Structures and Dynamics
Stress Analysis
Metallurgical Lab

If you're the man with extra *grey matter* who wants the chance to really use it, write us today. We'll put you in touch with a Firestone man who has your kind of *grey matter*, too.

SUBMINIATURE RELAY

New VG series of relays developed for aircraft and missile applications have a vibration rating at 15 g's from 55 to 2,000 cycles per second. Shock rating is 100 g's.

The VG relays, designed to meet Spec. MIL-R-57570 shock test II, are in the subminiature class. Relays measure less than ¾ cu. in. and weight is 1.3 oz. with a DPDT arrangement. Operating range is —65°C to 85°C and units with 125°C rating will be supplied on request.

Coil specifications call for standard operation at 24-29 volts d-c and maximum coil voltage is 38 volts d-c continuous with pull-in voltage rating at 18 volts maximum over the temperature range. Operating time is 6 milliseconds at 26.5 volts.

Life performance of VG series is said to be at least 100,000 operations at rated load. Elgin National Watch Co., Electronics Div., Elgin, Ill.

Circle No. 206 on Subscriber Service Card

PULSE GENERATOR

A new pulse generator is available that is completely transistorized. Completely self-powered by a 22½ volt battery with a useful life of 450 hours, the generator provides a pulse length from 0.5 to 3 microseconds.

Positive and negative pulses are continuously variable from zero to full amplitude to a 20 volt peak into an 800 ohm load. Rise and decay time is rated at 0.1 microseconds or less; tilt and overshoot at less than ±2%.

Repetition rate on internal sync is from 50 to 5,000 pps, and on external sync from 0 to 5,000 pps. Model 502 generator is housed in a case measuring 8½ x 5 x 4½ inches. Cubic Corp., 5575 Kearny Villa Road, San Diego 11, Calif.

ROCKET ENGINE HEAT EXCHANGER

An all-aluminum heat exchanger developed for rocket engine propellant testing at Reaction Motors, Inc. has a design temperature range from +100° to —325°F.

In the tests, liquid nitrogen will be vaporized in the shell side of the combination shell and tube unit at —320°F in order to cool liquid oxygen passing through the tubes at about —285°F.

Wanted!

Engineers who will accept the challenge of the most urgent program in the free world today...

Long Range Guided Missiles

Ten years ago there was only a handful of men in the country who said it could be done. Today, more and more engineers—their technological noses scenting the fact that engineering history is in the making—are picking up the gauntlet of the greatest engineering challenge American ingenuity has ever faced—the race against time and the phenomena of long range guided missiles.

Dr. E. R. van DRIEST, Chief Scientist, is nationally recognized for his work in aerothermodynamics. He has a BS, Case Institute of Technology; MS, University of Iowa; Ph.D., Cal Tech; and Sc.D, Technisch Hochschule, Zurich, Switzerland. Around his home, in Whittier, he finds ideal opportunities for the pursuits he and his family like best—horseback-riding, archery and other outdoor activities—perfect complement to the absorbing mysteries of his work.

Research and development that would ordinarily take years is today—of necessity—being telescoped into months. Problems of aerodynamics, thermodynamics, high temperature materials, aeroelasticity—that a decade ago were only theory in textbooks are today being solved. What's more, the production techniques necessary to turn these solutions into hardware have been evolved.

Major Missile Center

One of the major centers of this activity is North American Aviation's Missile Development Division. In 1945 North American started a program of research and development in this field. As far back as 1948, the first NATIV—North American Test Instrument Vehicle—streaked to trajectory altitude of 10 miles. One result of this type of pioneering was complete weapons system responsibility for the Air Force SM-64 Navaho Intercontinental Guided Missile—a gigantic task embracing almost every field of engineering.

JIM THOMPSON's career in missile engineering at North American began in 1951. Today, Jim is Group Leader of Flight Instrumentation at the Missile Test Facility, Patrick Air Force Base, Florida. The tropical climate there is ideal for his favorite sports—fishing and golf.

Progress Grows Apace

We can't give details here, or describe facilities, solutions, flight tests. But we *can* tell you this: a new engineering chapter is being written. It is reaching its climactic phase. There will never be a better time for you to become a Missile Engineer.

Are You This Kind of Man?

Can you break with tradition... leave conventional methods behind... and explore the unknown with the faith that in every obstacle lies the seeds of new successes?

MANUEL C. SANZ, Chief of Materials Research, found unique scope for his special talents at North American. This Chemical Engineer, with a Masters in Physics and Chemistry, is named as the inventor in a patent on the famous Chem-Mill Process. His son leads a Los Angeles school band—with a chem-milled baton!

If You Join These Men, We Promise You

a management climate which stimulates personal growth—and rewards it with responsibility, professional recognition and material benefits limited only by your own abilities. Your own academic stature can be constantly enlarged with our Educational Refund Plan—and some of the nation's finest universities are close at hand.

Write today for full particulars. If you're the man we're seeking, we'll be glad to arrange a personal interview *where you are now residing.*

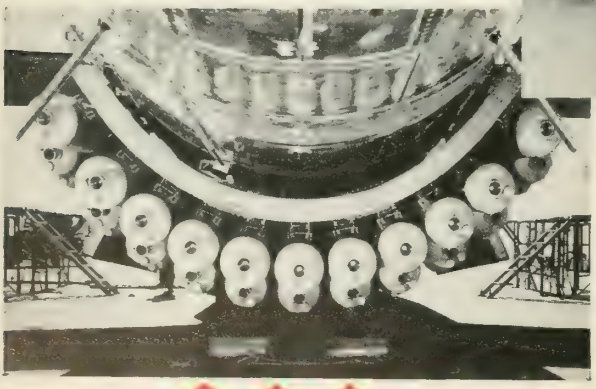
EXCEPTIONAL OPPORTUNITIES FOR SCIENTISTS AND ENGINEERS



in rocket development at Phillips Petroleum Company

The Rocket Fuels Division of Phillips Petroleum Company operates Air Force Plant 66, a multi-million dollar plant with modern facilities for research, development, testing and manufacture of solid propellant rockets. Exceptional opportunities and key positions are now open to scientists and engineers of proved experience and ability. Challenging opportunities are also available to recent technical graduates, with or without experience. Phillips Petroleum Company is a progressive, diversified company with assets of more than one billion dollars and an already *established reputation* in the rapidly expanding rocket field.

You are invited to write to our Technical Personnel Office, Rocket Fuels Division, Phillips Petroleum Company, McGregor, Texas. Your résumé will receive prompt, confidential attention. Interviews will be arranged for qualified applicants.

NEW EEMCO MOTOR

for new missile

. . . another example of the versatility of the nation's leading producer of motors and actuators for jet aircraft and missile systems.

SPECIFICATIONS FOR TYPE D-855

Type: DC motor with integral gear reduction
Terminal voltage: 24
Horsepower: 4.8 at 200 amps
Output RPM: 2600 minimum
Duty Cycle: 10 min. on, 30 min. off
Ambient temperature range: —65°F. to 250°F.
Minimum starting torque: 300% of running torque
Mounting pad: AND 20001
Cooling: Fan cooled with open thru ventilation
Weight: 17¾ pounds

EEMCO TYPE D-855, a DC motor with integral gear reduction, was designed for use in missiles of the latest concept. Like all **EEMCO** motors, as well as **EEMCO's** rotary and linear actuators, it packs maximum performance into minimum dimensions and weight. With a terminal voltage of 24, Type D-855 produces 4.8 HP at 200 amperes with a minimum RPM output of 2600. Duty cycle is 10 minutes on and 30 minutes off, with minimum starting torque at 300% of running torque. Ambient temperature range is —65° to 250° Fahrenheit. Type D-855 is fan cooled with open thru ventilation.

EEMCO has had many years experience in the exclusive design and manufacture of airborne motors and actuators. As a result, **EEMCO** is thoroughly skilled and equipped to produce these vital components that must operate unfailingly under the extreme environmental conditions encountered in today's supersonic aircraft and missiles. Thus **EEMCO's** extensive specialization in this field is playing an important part in the reliability of the most modern air weapons now being produced for the nation's defense.

SUBMINIATURE TRIMMING POTENTIOMETERS FOR THE

HOT SPOTS

IN YOUR ASSEMBLIES

BOURNS *Model 160*

TRIMPOT®

—new high temperature, high power design

This instrument operates reliably in high ambient temperatures, or wherever closely massed components generate localized hot spots. The TRIMPOT will withstand temperatures up to 175° C. (347° F.) with unimpaired efficiency. Lead wires are Teflon insulated. High power dissipation— 0.6 watt at 50° C. (122° F.)

You'll find every outstanding feature of the original Model 120 TRIMPOT—standard of the industry—built into the Model 160. 25-turn adjustments are made with a screwdriver on the slotted shaft. The shaft is self-locking, to provide stable settings. Resistance element is precision wound with low temperature-coefficient resistance wire. Unit withstands severe shock, vibration and acceleration. To assure its dependable performance under extreme environmental conditions, Bourns designed the Model 160 TRIMPOT to meet or exceed rigid government specifications.

Write for new descriptive literature.

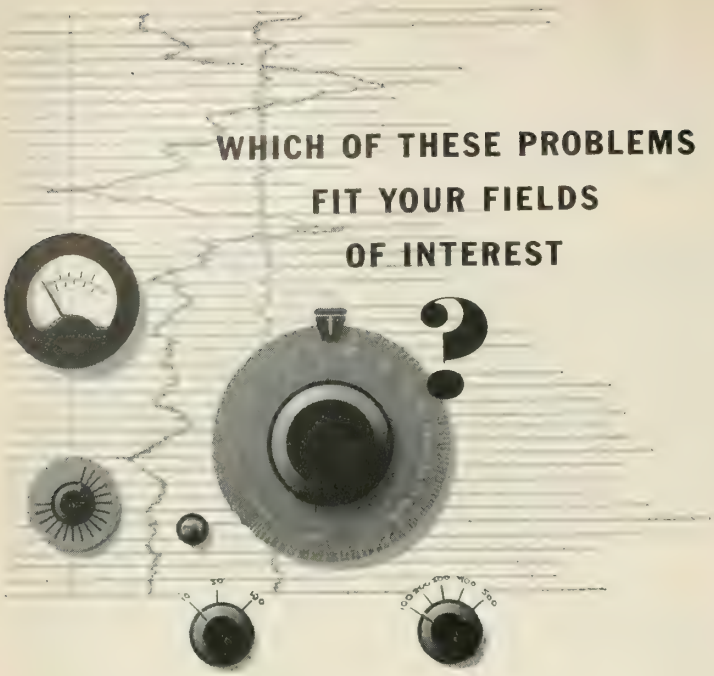
The Jet Propulsion Laboratory is an organization devoted entirely to scientific research and development. Covering an 80 acre area in the rising foothills of the San Gabriel mountains, north of Pasadena, it occupies an ideal location close to residential districts.

The working staff of the Laboratory consists of about 1250 people, all employed by the California Institute of Technology. The various projects are conducted under continuing contracts with the U. S. Government.

The prime objective of JPL is obtaining basic information in the various sciences related to missile systems development and in all phases of jet propulsion. Underlying the entire Laboratory activity, a major continuous program of fundamental research in the physical sciences is constantly in progress.



In its missile system and jet propulsion undertakings, the Laboratory maintains a broad technical responsibility, from basic research to prototype engineering. By virtue of this and the integrated nature of the JPL technical staff, each individual is drawn into close contact with the general field to which his specialized technical abilities contribute the most.

If you are interested in knowing more about our work and the specific employment opportunities now open, please send us an outline of your technical background and experience.

Bell Aircraft is continuing its pioneering in the fields of research aircraft and weapon systems. Testing techniques and equipment must be developed which will establish design acceptibility of radical new developments. The range of testing covers all prototype weapon systems and aircraft elements. Here are just a few problems typical of those we are now encountering.

1. Given the conditions for thrust chamber operation of a total propellant weight flow of 20 lbs. per second and a mixture ratio of 5 to give a chamber pressure of 600 psia; what new tank pressures would be required for a mixure ratio of 4 if the original tank pressures had been 1,000 psia on the oxidizer tank, and 900 on the fuel tank.

2. Develop test planning and group testing of varied projects involving radical airplane concepts and electronic systems for flight control and navigation.

3. In the design of a radar range calibrator test set, a digital counter with a frequency division of 627 is required. The circuit to be designed must operate properly under the following variable conditions:

1) Plate supply voltage is 300± 100 volts DC.
2) Filament supply voltage is 6.3± 2 volts AC.
3) Temperature range +100° C to -40° C.
4) Shock up to 50 g's.
5) Frequency range (counter input) up to 5,000 P.R.F.

If your qualifications place you in a position to help solve these challenging problems...or if you are now limited in the scope of your opportunity and would like to participate in any of Bell's widely diversified activities in other fields, write today: Manager, Engineering Personnel, Department U-1 **BELL AIRCRAFT CORPORATION,** P. O. Box One, Buffalo 5, N. Y.

VARIABLE FREQUENCY FILTER

A variable filter designed for use with vibration analyzers made by the same firm provides for measurement of amplitude and phase of vibration frequencies. The Model 1065 Variable filter permits tuning or scanning of the vibration spectrum over frequencies up to 30,000 cpm with a rated accuracy of 5%, and within 10% from 30,000 to 300,000 cpm.

The unit operates from 110 volts, 60 cycles, single-phase power. Bandwidth is ±5% of the nominal frequency to the 3 db-down points. The Model 1065 filter is inserted between an IRD velocity pickup and the vibration analyzer which is being used. International Research and Development Corp., Columbus, Ohio.

HIGH TEMPERATURE RIVET

New stainless steel rivet for aircraft and missile structures requiring high strength at high temperatures has an 85,000 psi shear strength at 800°F. Room temperature shear strength is more than 100,000 psi.

Designated the Cherry "600," the new rivet uses a stem and sleeve of A-286 stainless steel, heat-treated and aged for optimum strength and corrosion resistance.

Write: Townsend Co., Dept. M/R, Box 2157-Z, Santa Ana, Calif.

MISSILE POWER SUPPLIES

Four new all semiconductor dc-dc converters have been announced for use as missile beacon power supplies and other mobile applications. Units are available with inputs of 12 and 28 volts dc and filtered dc outputs of 325 volts at both 100 and 200 milliamperes.

Units are supplied in hermetically sealed packages measuring 3 1/16 x 3 3/16 x 2 5/8 inches. The supplies use two power transistors in an oscillator to interrupt the dc input.

Silicon power diodes and special capacitors are used in the rectifier circuit. Regulation is rated as 20% on standard units, and 0.5% regulation with special input-output voltages can be provided on a custom basis. Power Sources, Inc., 6 Schouler Court, Arlington, Mass.

MOLYKOTE® LUBRICANTS . . .

ALREADY SOLVING PROBLEMS IN THE AGE OF ASTRONAUTICS

Born in the "fringe area" of industrial lubrication, MOLYKOTE Lubricants have grown under the pressure of the toughest problems industry has to offer. Extreme pressures and temperatures: unusual environments, high starting friction, resistance to centrifugal force, obstinate fretting . . . MOLYKOTE has solved many. Truly, MOLYKOTE has been called "Industry's Most Versatile Lubricant".

To the Age of Astronautics MOLYKOTE brings ● THERMAL STABILITY, retaining its lubricity from -300°F to 700°F in air. 2000°F in vacuum ● CHEMICAL STABILITY, resists all but a few strong acids ● A NATURAL AFFINITY for adherence to metal, rubber, plastics, etc. ● A FAVORABLE LUBRICANT structure. Low friction sliding surfaces are an integral part of the molecule ● RESISTS PRESSURES beyond the yield point of any metal.

Send today for complete data on the entire line of MOLYKOTE Lubricants.

Honeywell's infra red devices can

Detect lighted cigarette over half mile away

IT'S PRETTY amazing—when you realize the average cigarette radiates only two watts. This gives some idea of the sensitivity—and range—of the Honeywell infra red systems.

And from there it doesn't take a great deal of imagination to realize the effectiveness of military equipment using these detectors.

Developed after years of research, economical, non-jammable Honeywell systems are now being produced for use on classified weapons.

Solution of the infra red problems adds one more important field to Honeywell ordnance division's array of weapons systems. And it puts us in an excellent position to take on new developments.

Experts in our ordnance division can draw upon a pool of over 25,000 skilled men and women in research, engineering, design and development, production and field service. And standing behind them is over seventy years of engineering and production know-how.

If you require development work in the areas of missile equipment, fuzing, fire control, underwater ordnance or special products, Honeywell ordnance division would welcome your inquiry. Phone, wire or write to Honeywell Ordnance Division, Dept. MI-1-09, Hopkins, Minnesota.

Honeywell Customized Weapons Systems

Warheads; Infra red systems and components; Test, check-out and training devices; Transistorized converters, inverters, rectifiers; Thermal batteries; Mechanical, electro-mechanical and electronic fuzing; Sonar detection systems; Ground-based fire control systems; Stabilized platforms.

missile literature

HIGH CURRENT RECTIFIERS. An 11-page brochure, No. ECG-148A, of application notes and graphical data on General Electric's 4JA60 series of small high current silicon rectifiers is available. The new units handle up to 10 kilowatts in a three phase circuit. Write: General Electric Co., Dept. M/R, Semiconductor Products Dept., Electronics Park, Syracuse, N. Y.

MAGNETIC SHIELDING. A 33-page brochure entitled Data Sheets 101 (1957), describes construction features, performance characteristics and typical applications of non-shock sensitive, non-retentive Fernetic and Co-Netic magnetic shielding material. There are 14 pages of illustrations and 5 pages of graphical data. Write: Magnetic Shield Division, Perfection Mica Co., Dept. M/R, 20 N. Wacker Drive, Chicago 6, Ill.

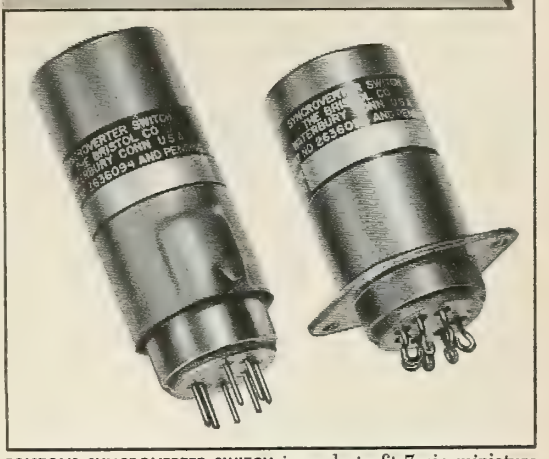
TAPE RECORDER. A 24-page bulletin No. 1561B describes complete characteristics of a new magnetic tape recording and playback system for handling stress, pressure, temperature and vibration data. Detailed photographs of different parts of the Consolidated DataTape system are also provided. Write: Consolidated Electrodynamics Corp., Dept. M/R, 300 North Sierra Madre Villa, Pasadena, Calif.

ELECTRONIC COMPONENTS. A 15-page catalog of AN connectors, RF connectors, Rack and Panel connectors and RG-/U coaxial cables stocked by Amphenol distributors for same-day delivery. Catalog IEC-2. Write: Amphenol Electronics Corp., Dept. M/R, 1830 South 54th Ave., Chicago 50, Ill.

TECHNICAL LITERATURE

TUBE MANUAL. A new edition of the Radio Corp. of America receiving tube manual, RC-18, has been announced. Technical data on 575 receiving tubes and cathode ray tubes is included. (Price $.75). Write: Commercial Engineering, Tube Division, Radio Corp. of America, Dept. M/R, Harrison, N. J.

TEST EQUIPMENT DATA. A comprehensive compilation of descriptive data on more than 1300 electronic test equipments has been published to fill a need in the electronics industry for a handy time-saving reference file of information in this field. Information comes in five volumes of hard cover binders. Periodic additions and revisions will be published. The complete set, including revisions costs $170.00. Write: Carl L. Frederick & Associates, Dept. M/R, 4630 Montgomery Ave., Bethesda 14, Md.



STORAGE BATTERIES. Yardney Electric Corporation, 40-50 Leonard St., N.Y. 13, N.Y. announces publication of a new brochure on its line of SILVERCEL* (silver-zinc) and SILCAD* (silver-cadmium) rechargeable storage batteries. The outstanding features of Yardney cells are outlined in an attractive three-color folder. These advantages include light weight, small size, flat voltage characteristics and high current output. Copies of the new brochure will be mailed free on request by the Yardney Electric Corp. Ask for "Compact Power by Yardney."

RECORDING CAMERAS. Multiple-purpose precision data recording cameras are the subject of an eight page, illustrated brochure offered by Flight Research, Inc., Richmond, Va. Small and lightweight, the MULTIDATA cameras permit automatic, synchronized motion picture or single frame operation. Full operating specifications and details of construction are given for both the MOD III 16mm and MOD IV-C 35mm MULTIDATA cameras. Complete information is contained in the bulletin. Write for a copy to Flight Research, Inc., Post Office Box 1-F, Richmond, 1, Va.

MINIATURIZED GEAR BOXES. A revised four-page, two-color illustrated brochure, number SW-1, describes and illustrates Southwestern's miniaturized gear boxes, miniaturized vibration-resistant pressure switches, and light-weight, compact screwjack actuators. Southwestern Industries gear boxes are designed for electronic and instrument applications, servo mechanisms, computers, small actuators and electronic components. Write: Southwestern Industries Inc., 5880 Centinela Ave., Los Angeles, Calif.

SERVO CONTROL VALVES. Cook Research Laboratories Division of Cook Electric Company, Chicago 14, Ill., has released Volume 3, No. 2 of the Cook Technical Review. This issue of 28 pages deals with electrohydraulic servo valves. Part I presents basic information relative to the types and characteristics of high response servo control valves. The subsequent part describes the various types of valves which are commercially available and discusses the selection of electrohydraulic servo valves and their system application. Bernard A. Johnson, Project Engineer; Lee D. Schmid, Senior Engineer; and Jay Warshawsky, Technical Director, Automatic Control Systems Section, all of Cook Research Laboratories, are the authors of this issue of The Cook Technical Review. The price of this issue of the Cook Technical Review is $1.00 per copy in U.S. and Canada ($1.25 in other countries).

WHAT'S NEW AT BRISTOL...

BRISTOL'S SYNCROVERTER SWITCH is made to fit 7-pin miniature tube socket *(left)* or ¾-in. diameter chassis hole *(right)*. Covered by patents.

"Most reliable miniature chopper we've tested!"

That's the playback we're getting from electronic engineers all over the country on the high-performance Bristol Syncroverter® switch. One engineer writes:

"In seven years of experience in applying similar devices, we have not found a chopper as reliable . . . after our tests no deterioration in performance was found, and we believe there is no equivalent meeting our requirements."

Another electronics engineer comments on his life-tests:

"The switch has passed the 1000-hour mark without the slightest degradation of the wave form."

The Syncroverter switch has a normal *operating life of thousands of hours*. It's a polarized, SPDT, non-resonant switch that provides break-before-make action in synchronism with a sine or square-wave driving current anywhere in the frequency range of 0 to 2000 cps. In addition to reliability and long life, it's noted for light weight (only 1.7 ounces) low noise level, and clean wave form.

Write today for free bulletin on the high-performance Syncroverter switch. The Bristol Company, 150 Bristol Road, Waterbury 20, Conn. 6.10

TYPICAL OPERATION

SUCCESSOR TO VTVM

measure amplify uv...uua

Universal DC Meter

This new microvolt-ammeter-amplifier will measure as little as 10 μv or 10 $\mu\mu$a with accuracy. It may also be used as a DC amplifier with up to 80 db gain and only 10 μv drift. A zero-center mirrored scale provides instant polarity indication. Utilization of Kay Lab's chopper stabilized circuit provides versatility, accuracy, and stability that is unobtainable with conventional VTVM's. The Model 203 is the ideal general purpose laboratory meter, production test set, or null meter.

SPECIFICATIONS

- 100 μv to 1000 v fs
- 100 μa to 100 ma fs
- 25 ranges
- 100 megohms input
- 80 db gain as amplifier
- 10 μv equivalent input drift
- 1 volt output
- Price $550.

people

Well-known general buries a smile as world's top ballistic missile expert says: "I read in LIFE magazine that we are supposed to have fired a missile 3,000 miles . . ." Some of those at the head table for the Honors Night dinner at the recent annual meeting of the American Rocket Society in New York included (left to right): REAR ADM. JAMES S. RUSSELL, Chief, Bureau of Aeronautics; MRS. JAMES H. WYLD, retiring ARS President, NOAH DAVIS; ABMA Development Director, WERNHER VON BRAUN; ABMA Chief, MAJ. GEN. JOHN B. MEDARIS; CMDR. ROBERT M. TRUAX, USN, AF WDD; MRS. ROBERT H. GODDARD.

Maybe it was the hour, or maybe it was Defense Secretary Wilson's November memorandum that joined well-known science writer WILLY LEY and Boeing engineer NORMAN BAKER in deep contemplation.

Eager beaver KURT R. STEHLING, propulsion chief, NRL's Project Vanguard, listened.

DR. S. FRED SINGER, Professor, Maryland University Physics Department, had a point.

The points, in fact, that were made were many and ranged far into the early morning hours.

Rocket pioneer and former ARS President G. EDWARD PENDRAY describes a fundamental principle.

From Peenemunde to Redstone—Former German professor HERMANN OBERTH, father of space flight, now special consultant to VON BRAUN at ABMA.

Making the round of hospitality suites was a tough circuit; playing host was tougher.

Curtiss-Wright's G. S. WING seems to have doubts as to where it all will end.

And two just couldn't take it any longer.

people

Peder W. Larsen, formerly Senior Military Officer at the Royal Aircraft Establishment at Farnborough, England, where he was responsible for the development program of Army guided missiles, has been appointed manager of government projects of PSC Applied Research Ltd.

Bell Aircraft Corporation's new Aircraft Division announces four appointments: **John W. Rane, Jr.,** director of engineering and sales; **George D. Ray,** chief engineer; **Stanley W. Smith,** chief project engineer; **John J. Weisbeck, Jr.,** contracts manager.

Eduard Baruch, president of Heli-Coil Corporation, a subsidiary of Topp Industries, Inc., has been elected a vice president and director of the parent firm.

H. C. Riggs has been named coordinator of missile applications engineering by the Exide Industrial Division of The Electric Storage Battery Co., Philadelphia.

KING

Dr. Donald D. King, formerly director of the Radiation Laboratory at Johns Hopkins University, was elected vice president-research for Electronics Communications, Inc., a subsidiary of Air Associates, Inc.

Alden R. Ludlow, Jr., has been appointed director of sales for U.S. Industrial Chemicals Co., Division of National Distillers Products Corp.

Roy S. Fisher was elected vice president and named director of sales for National Vulcanized Fibre Co.

John S. Anderson, president of Aeronautical Radio, Inc., has been reelected to a two-year term as vice chairman of the Radio Technical Commission for Aeronautics.

C. Charles Miesse, a specialist in liquid propellant engines, formerly with Aerojet-General Corp., has been named supervisor of the newly created combustion section at Armour Research Foundation of Illinois Institute of Technology, Chicago, supervising activities in area of combustion, jet engines, liquid rocket engines and gas turbines.

David D. Stone has been appointed vice president in charge of sales and customer relations for Wyle Laboratories, El Segundo, Calif.

Robert L. Clark has been appointed to head Ryan Aeronautical Co.'s Manufacturing Division.

Charles E. Miller has been named head of engineering services for the Pacific Division, Bendix Aviation Corp. **William H. Chester** and **Charles W. Thomas** have been appointed asst. supervisors of the telemetry engineering section of the division.

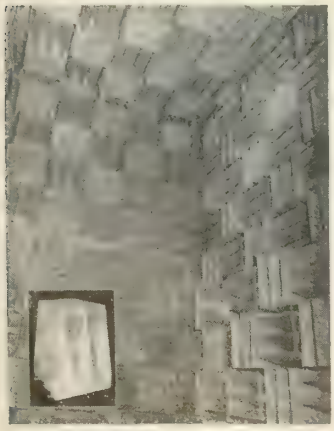
Dr. William B. McLean, technical director of the Naval Ordnance Test Station, has received a $25,000 cash award for his role in the development of the Navy's *Sidewinder* air-to-air missile. Decorations and citations were awarded the following men, who developed the first guided missile, the TDR-1, launched in wartime against the enemy: **Commodore Oscar Smith** (Ret.), **Capt. Robert Jones** (Ret.), **RADM D. S. Fahrney** (Ret.), **LCDR Fred Wallace, Lt. William Bowlin, LCDR John Burrell, LCDR William Bailey, Capt. S. E. Jones,** and **Capt. G. E. Merrill.**

John N. Kerr, former chief of associated projects at Northrop Aircraft, Inc., has been appointed vice president of Horkey Associates.

BAILEY

John T. Bailey has been named quality control director for Bell Aircraft Corp.'s Weapon Systems Division; **Raymond C. Sears** was named director of quality control for Aircraft Division. New assignments in the Rockets Division, a unit of the Weapons Systems Division, are **Floyd H. Walters,** director of manufacturing; **R. Dewey Rinehart,** director of engineering; **Harry A. Ferullo,** director of programs; **Stephen D. Krull,** director of tests; **Joseph R. Piselli,** manager of customer relations and sales; **Melvin J. Blessing,** manager of contract administration.

Phillip Movitz, staff asst. to the division general manager, Grand Rapids Division of Lear, Inc., has been promoted to quality control manager. **J. C. Owen** has been named manager of the advanced engineering department of the division.



R. J. Sullivan has been named director of quality control and **Conrad Hohmann,** asst. chief engineer-special airborne devices, for Vickers Inc. **Mr. Sullivan** will be responsible for coordination of quality control at Detroit, Omaha, Joplin (Mo.) and Jackson (Miss.) divisions.

SHAW

George B. Shaw, vice president-procurement for The Martin Co., has been named president of Martin International, a new subsidiary company which will develop world markets for nuclear powered electrical generating systems.

Dr. Adolph K. Thiel has been appointed assistant program director for the *Thor* intermediate range ballistic missile program.

Inset shows design and construction of typical AN-ECK-OIC® WEDGE

Engineering Laboratory Anechoic Chamber installation Pratt & Whitney Aircraft East Hartford, Connecticut

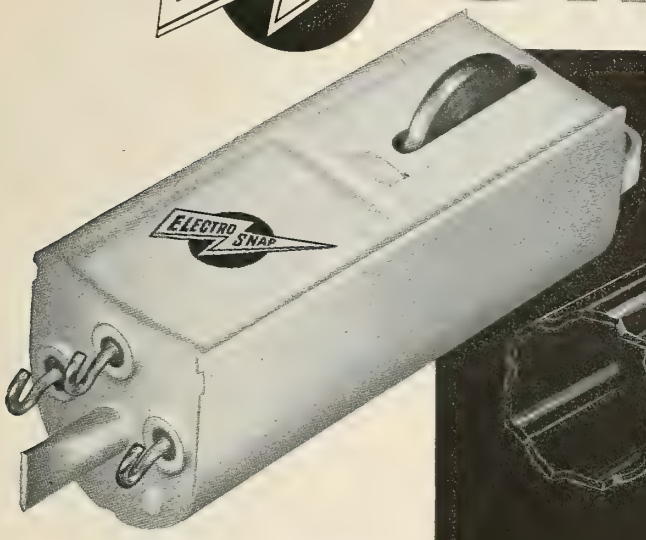
AN-ECK-OIC® WEDGES

Another AN-ECK-OIC® WEDGE installation

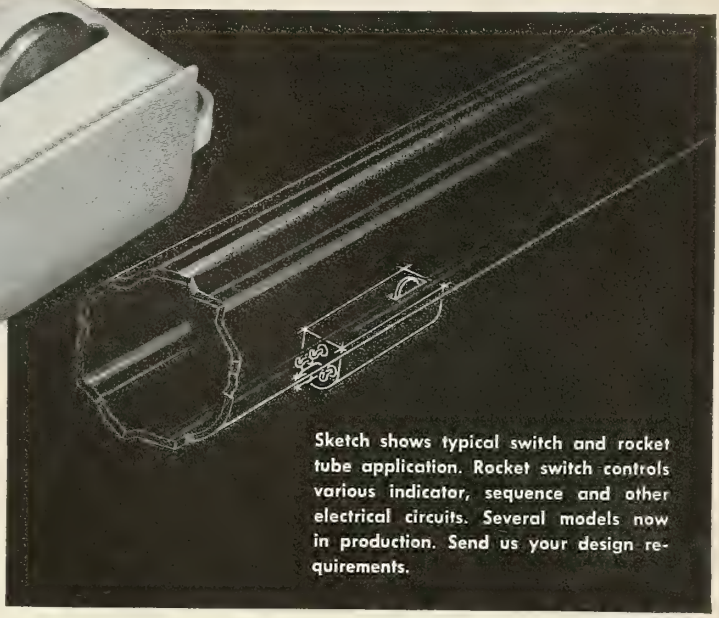
Anechoic Chambers are recognized as valuable facilities for analyzing noise sources in automotive and aircraft engines, components, auxiliary machines, electric and audio equipment.

Recent Anechoic Chamber installations have been constructed for General Electric Co., Pittsfield, Mass., The National Bureau of Standards, Washington, D. C.

In many of the Anechoic Chambers in the United States, AN-ECK-OIC® Wedge units made by THE ECKEL CORPORATION provide the near perfect sound absorption.



For the silencing of Engine Test Cells, Firing Ranges, noisy machines and equipment consider the use of ECKOUSTIC® Sound Control Panels —product of THE ECKEL CORPORATION.



The Eckel Corporation Engineering and Installation organization can be helpful to you in solving your sound laboratory problems.

new ELECTRO SNAP ROCKET SAFETY SWITCH

Sketch shows typical switch and rocket tube application. Rocket switch controls various indicator, sequence and other electrical circuits. Several models now in production. Send us your design requirements.

...from the makers of the leading line of HERMETICALLY SEALED LIMIT SWITCHES

Electro-Snap has developed a complete line of hermetically sealed limit switches to bring the ultimate in environment-free switching to aircraft control circuits. With a record of dependability totaling millions of hours, Electro-Snap Hermetically-Sealed Switches have been used as original equipment by major aircraft producers—on standard and experimental aircraft for both commercial and military use. They are also being widely used for retro-fitting, to modernize existing control circuits for the more exacting demands imposed on today's aircraft. If aircraft switching is your responsibility, you should know about this modern line of switches for modern aircraft. Write for specifications.

To meet modern aircraft requirements, Electro-Snap has developed and perfected this, the first truly hermetically sealed rocket switch. Because both the basic switch and the operating mechanism are sealed in an inert gas, the switch is unaffected by extreme heat, or cold, humidity, water, oil or temperature cycling. Tipping action of the actuator prevents jamming by ice. Completely environment-free, the dependability of the switch and its operating action have been thoroughly proved on today's newest fighter aircraft.

IMPORTANT CHARACTERISTICS

Contact Arrangement ..... SPDT, 1 circuit

Capacity.....4 amps. resistive, 2.5 amps. inductive at 30v DC.

Electrical and Mechanical Life.....150,000 operations min.

Vibration and shock resistance.....Excellent

Full information is available on request. Write for Data Sheet RY-1.

ELECTRO-SNAP SWITCH & MFG. CO.

4252 West Lake Street, Chicago 24, Illinois

We will meet your design requirements—send us your prints

Labor Dept. Finds Training Lack

The aircraft and missile industry is neglecting apprentice training in a large majority of its major plants and is generally falling short of its goal of meeting skilled manpower needs, according to the Dept. of Labor.

Results of a recent Labor survey show that apprenticeship training is being neglected entirely in 99 out of 143 plants employing more than 400,000 persons each. Only about one-third of the facilities surveyed were found to have some kind of junior training projects under way.

Labor's Bureau of Apprenticeship found that aircraft and missile firms not participating in apprentice programs are relying on short-term training, upgrading, recruitment from other plants, and other haphazard methods for skilled workers. It noted that a few plants are doing excellent work in training skilled craftsmen, but that they are too few to carry the training responsibility for the industry.

The Labor report states further that the chronic skilled-manpower shortages in the industry over the past few years point up the need for developing adequate training programs in many plants not presently training workers to meet their skilled manpower needs.

Full text of the Labor study, entitled *Training in the Aircraft Industry*, is available free from the Publications Branch, Bureau of Training and Apprenticeship, Dept. of Labor, Washington 25.

Douglas Employes Get Pay Raise

More than 7,000 salaried employes at the five divisions of Douglas Aircraft Co. were scheduled to receive a pay increase ranging from 4% to 7% effective January 7. Average rate of increase was placed at more than 5%.

The new wage hike effects all salaried employes except those represented by the Southern California Professional Engineering Assn. Similar upward adjustments are scheduled by the company for some 3,400 represented by SCPEA upon approval of the pay formula by the union membership.

No Seniority Loss In Missile Move

Transfer of employes in Lockheed Aircraft's Missile Systems Div. from Van Nuys to the San Francisco Bay area will involve no loss in seniority. Company has signed a new wage agreement with Local 508, International Assn. of Machinists.

Republic Launches EngineeringTraining

Republic Aviation Corp. this month will inaugurate a non-credit, college-level training program to be conducted on company time for its engineering personnel. A series of 15-week courses taught by Republic engineers will extend from drafting room mathematics to stress analysis. The company expects enrollment eventually will reach 1,500.

The new program is designed to ease the shortage of trained technicians by upgrading the qualifications of personnel now employed, according to Republic president Mundy I. Peale. Classes begin on January 7.

Two Missile Firms Plan Denver Plants

Two missile accessory firms, both subcontractors to The Martin Co. in its *Titan* ICBM project, are planning to open new facilities near Martin in Denver. One is Associated Missile Products Corp. located at Pomona, Calif. and the other Hallamore Electronics Co. of Anaheim, Calif. Latter is a division of Siegler Corp. of Chicago, Illinois.

Associated Missiles will locate a field office at 3550 So. Inca St. and

Another first!

WESTINGHOUSE-BALTIMORE
Revolutionizes Radar Design!

PARABALLOON *Acclaimed "A Major Breakthrough for Air Defense"*

The Paraballoon is a ground radar antenna that can be inflated or deflated like a balloon, folded and packed into air lift containers for tactical operations.

Westinghouse engineers at the Electronics Division in Baltimore developed the Paraballoon for the Rome Air Development Center . . . and every conventional radar antenna became obsolete over night! *Aviation Week* headlined the news with a cover story in their October 22nd issue . . . and *Life Magazine* featured it on November 5th.

The Paraballoon is a radically different type of ground radar antenna. Unlike the conventional antenna which weighs over 10,000 pounds, the Paraballoon weighs only 1,700 pounds. With it, a trained crew of 20 men can set up a complete radar station in two hours. Major General Stuart P. Wright, Commander of Rome Air Development Center, was quoted in *Aviation Week* as saying that the Paraballoon is "A major breakthrough for our air defense."

This is just one of many firsts for the engineers at Westinghouse-Baltimore. Inheritors of the Westinghouse pioneering tradition, and leaders in electronics developments, the engineers at Westinghouse-Baltimore are engaged in vital defense projects far beyond the "state of the art." Here, the engineer has unlimited opportunities—in a company where engineers are respected and rewarded for their contributions.

Investigate the opportunities open to you at Westinghouse-Baltimore.

Picture of a young man

Planning a Successful Future!

Success doesn't just happen to a company or to an individual. Success comes as a result of clear thinking and long-range planning.

And that is just what the young engineer in the picture is doing. He is studying the many possibilities of a career in guided missiles.

The book he is reading is entitled "Your Future in Guided Missiles with Bendix". It is one of the most complete guides to job opportunities in the guided missile field. It also contains a detailed background of the functions of the various engineering groups such as systems analysis, guidance, telemetering, steering intelligence, component evaluation, missile testing, environmental testing, test equipment design, reliability, propulsion and other important engineering operations.

Here is exactly the type of information that every ambitious engineer should have if he is concerned about his future. A copy of this thirty-six-page book is available to you. Just fill in the coupon. It may help you plan your successful future.

expects to maintain about 60 to 65 engineers at the new facility. It will be headed by William Entrickin, former general manager of AMF's Micro-Pak Division in Colorado Springs.

Hallamore plans to open its Denver office at 1301 W. Third Ave. later this month and expects to expand by late 1957 to a staff of between 500 and 600 employes and payroll of about $300,000.

Pentagon has clamped a top secret cloak on the activities of both companies in the *Titan* project, a positive indication they are both key producers in the vital missile program.

Aircraft, Missiles Top $3 Billion

Air Force and Navy contract awards in October 1956 for aircraft, missiles and drones and related equipment totaled $387 million raising their total obligations for the first quarter of fiscal 1957 to $3,235,000,000.

Of this amount, AF obligated $181 million in October and $2.19 billion for the four months. Navy placed $206 million in orders in October and $1,045,000,000 for the four month period since July first.

Air Force spending, meanwhile, totaled $613 million in October and $2,117,000,000 from July through October whereas Navy figures were $169,000,000 and $580,000,000 respectively. Total spending for both services for the Fiscal 1957 first quarter in aircraft and missile categories amounted to $2,697,000,000.

Aviation Industry No. 1 Employer

The nation's aircraft industry, including an ever-increasing activity in guided missile development and production, became the nation's largest commercial employer in 1956, according to Aircraft Industries Assn.

AIA's year end report placed average industry employment at 800,000, an estimated 50,000 above the automobile industry in second place. It also noted that aircraft and missile workers increased their hourly earnings from an average $2.17 in 1955 to $2.31 by September 1956 with the trend still on the increase at the year end.

AIA also predicted a substantial change in the proportioning of Defense aircraft and missile orders in the future. By 1958, it said, military aircraft and related equipment procurement probably will assume a ratio of 65-to-35 in favor of manned aircraft over missile.

By as early as 1961, however, AIA viewed the possibility this ratio may become 50-50.

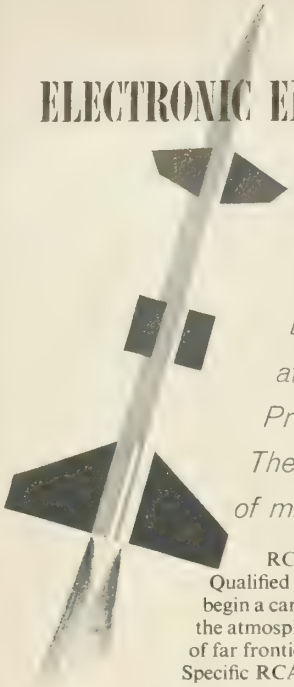
- Technical planning (advanced design)
- Proposals

Now's the time to take inventory. Do as businessmen do; it's smart to take stock of your progress and compare—

- ☐ Opportunity to work with leading technical authorities in the field.
- ☐ Work assignments that demand your best skills, give you full scope.
- ☐ Important responsibility without excessive supervision.
- ☐ Opportunities to advance your education in fine graduate schools.
- ☐ Maximum training with assignments necessary to your self-development in a series of brand new fields.
- ☐ Tremendous growth opportunities where your security is assured in a field marked for great strides.
- ☐ Top scale salaries at all levels, in full recognition of your skills.
- ☐ Frequent professional advancements.
- ☐ Good, pleasant suburban communities —minutes from work.
- ☐ Entertainment and cultural facilities of New York City just 50 minutes away.
- ☐ A year-round mountain lake resort in your backyard.



To find out just where YOUR *present skills fit in with the growing RMI picture, drop us a note or card. (Include address and phone number.) For immediate action, ask for an application form, or send complete resume to* ***Supervisor of Technical Personnel***

ELECTRONIC ENGINEERS...

become one of the first staff members of RCA's new ENGINEERING OPERATION at WHITE SANDS Proving Ground. The very nerve center of missile electronics!

RCA is new to White Sands! Qualified electronic engineers can now begin a career in a responsible position where the atmosphere crackles with the stimulation of far frontiers in missile electronics. Specific RCA assignments are in missile electronics, ground support systems, missile guidance and complex launching systems. You must, of course have your EE, ME or physics degree, several years' electronic design experience . . . and must be familiar with one of these fields:

System and sub-system analysis
Reliability data control
Evaluation of new components
Internal instrumentation
Equipment control
Data analysis

Projects will relate to sub-systems such as:

PRECISION RADARS
DIGITAL DEVICES
ANALOG DEVICES
DATA PROCESSING EQUIPMENT
FIRE CONTROL
DATA SIMULATION

Start at an excellent salary . . . A full program of liberal benefits gives your income added security. RCA's Tuition Refund Plan will provide for advanced studies. RCA pays relocation expenses.

ARRANGE CONFIDENTIAL INTERVIEW WITH ENGINEERING MANAGEMENT

Send complete resume to:

RADIO CORPORATION of AMERICA
DEFENSE ELECTRONIC PRODUCTS

West Coast Stresses Engineer Shortage

Los Angeles Council of Engineering Societies, acting jointly with the Technical Societies Council and Consulting Engineers Assn. have set aside February 18-22 as Engineering Week in Los Angeles. Its dual purpose will be to focus public attention on the growing shortage of engineers and their importance to the well-being and security of the nation.

General chairman of the activity will be J. Calvin Brown, a past national president of the American Society of Mechanical Engineers. Guest speaker at a banquet February 21 at the Statler Hotel will be Donald W. Douglas, president of Douglas Aircraft Co. Douglas also will be presented an award in recognition of his contributions to engineering and the Southern California aircraft industry.

Aerojet to Expand Plastics Activity

Aerojet-General Corp. has announced plans for major expansion of its structural plastics group within its Solid Engine Division. The program calls for new buildings and equipment to facilitate plastics research, development and manufacturing.

Main areas of activity for the group, headed by E. L. Rucks, will be in the fields of pressure vessels, thermal insulation and missile/rocket components.

Minn-Honeywell Forms New Division

Minneapolis-Honeywell Regulator Co. is combining the operations of its Doelcam Division and Transistor Division into a single organization identified as the Boston Division.

The new M-H unit will have two sections—semiconductor products and instruments—under division v.p. and general mgr. George J. Schwartz.

Employment Up in San Diego Area

Employment by San Diego's four major aircraft and missile manufacturers or subcontractors totaled 50,898 on December 15 marking an increase of 1,550 over November 20.

Convair reported 35,022; Rohr Aircraft Co. 7,148; Ryan Aeronautical 5,928 and Solar Aircraft 2,800. Convair employment increased 1,356 in the preceding two-week period.

RECENT BREAKTHROUGHS IN SUPERSONIC AND HYPERSONIC KNOWLEDGE AND TECHNOLOGY— BASIS OF MAJOR RESEARCH AND DEVELOPMENT ACCELERATION AT REPUBLIC AVIATION

Alexander Kartveli, Vice President in Charge of Research and Development, Invites the Inquiries of High Calibre Engineers and Scientists

Recent discoveries justify a large scale, long range integrated attack on all the complex, interrelated aspects of passage through the upper atmosphere, in the opinion of Alexander Kartveli, creator of Republic's famous family of Thunder-Craft.*

Republic's R & D activities are now being materially augmented and accelerated to speed the exploration of this new knowledge and technology. The broad areas under study are:

- **Hypersonic and Satellite Weapons Systems.**
- **Advanced Propulsion Systems.**
- **Nuclear Energy Applications to Aircraft.**
- **Capabilities of Materials in Hypersonic and Nuclear Environments.**
- **Electronic systems development to exploit the full potential of the most radical concepts of flight.**

The quality of the opportunities for creatively unhampered professional men with specialized experience in many fields is evident. Republic welcomes your inquiries regarding positions in any one of the areas outlined:

Positions Open At All Levels

NUCLEONICS
ELECTRONICS
SERVOMECHANISMS
PROPULSION
STRUCTURES
FLUTTER & VIBRATION
DYNAMICS
AERODYNAMICS
THERMODYNAMICS
FIRE CONTROL SYSTEMS
FLIGHT CONTROL SYSTEMS
INERTIAL NAVIGATION
INFRA-RED
OPERATIONAL ANALYSIS OF WEAPONS SYSTEMS
AIRFRAME AND SYSTEMS DESIGN
MATERIALS

*Each Thunder-Craft in turn has represented a significant advance in aircraft design. Latest member of this famous family is the incredible F-105 Thunderchief, most advanced USAF fighter-bomber — supersonic and nuclear-weapons carrying.

Please forward comprehensive resume in confidence to David G. Reid, Engineering Personnel Mgr.

FROM THE LAND, AND FROM THE SEA...

The Terrier Clears the Air!

Convair's versatile Terrier missile is now seeing land duty with the U.S. Marine Corps—affording you *new* and *mobile* protection! Already operational at sea with the U.S. Navy, the Terrier's new mobility is provided by launchers and handling equipment developed specifically for ground use.

The Terrier gives the Marines tremendous and accurate firepower where they want it, when they want it—to destroy an invading aircraft.

Produced by **Convair-Pomona** in cooperation with the **U.S. Navy Bureau of Ordnance,** the Terrier now can clear the air from both land and sea for your protection!

SOVIET MISSILES AND ASTRONAUTICS BEHIND THE IRON CURTAIN

"CUSTOMER SERVICE"

Extra diligent customer service is another outstanding characteristic of Narmco's continuing efforts to provide the aircraft industry with the most advanced structural materials.

Users of Narmco materials have at their constant service a field engineering organization supported by the industry's most experienced team of research, development and testing authorities devoted exclusively to structural plastics and adhesives.

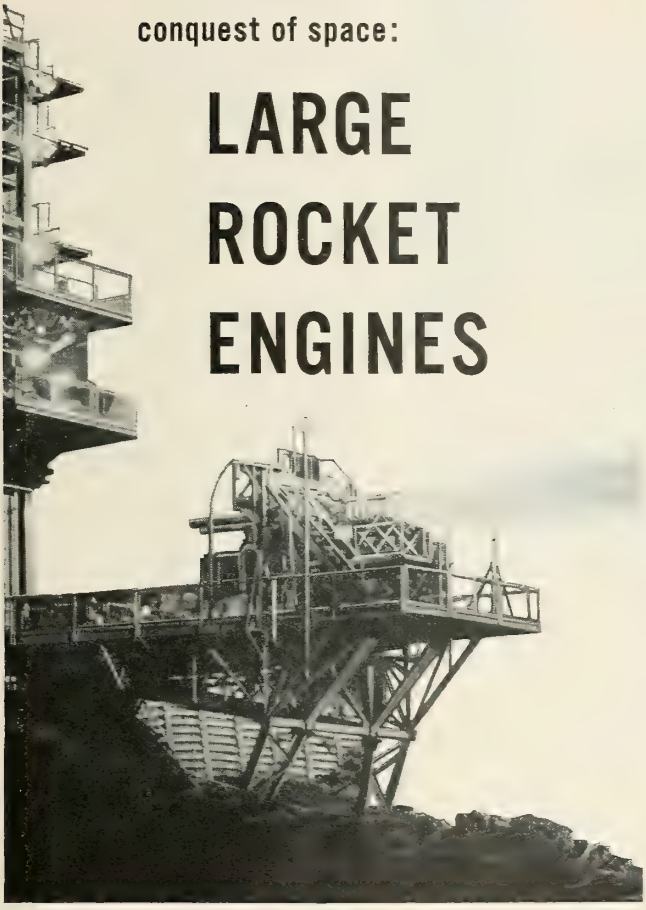
When problems—large or small—involve the application of structural adhesives or structural laminating, you can count on Narmco for the kind of assistance that leads to a prompt solution—and better aircraft components. Extra diligent customer service from Narmco can also lead to more efficient, more economical production!

Narmco Resins and Coatings Company is a prime manufacturer of a wide variety of high strength "Metlbond" structural adhesives. "Conolon" laminating materials, and coated fabrics—each specifically designed to meet the requirements of either primary or secondary aircraft construction. Narmco also produces an extensive line of putties, resins and sealers for use in the fabrication of aircraft components.

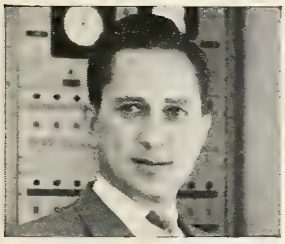
For over a decade, Narmco structural materials have been widely utilized in commercial and military aircraft, wherein they have demonstrated their utmost reliability in high performance applications.

NARMCO

PIONEERING THROUGH RESEARCH



Narmco technical field representatives throughout the United States and Canada can assist in solving your structural design problems quickly, efficiently and economically. For immediate assistance, write, wire or telephone . . .



NARMCO RESINS & COATINGS COMPANY, Dept. 872 **600 Victoria Street, Costa Mesa, California**

Wanted: Pioneers for man's last frontier

Help us build power for the conquest of space:

LARGE ROCKET ENGINES

WILLIAM J. CECKA, JR., 35, aeronautical engineer, (Univ. of Minn. '43), was called from North American by the Air Force for experimental rocket work in 1944. On his return, he progressed rapidly: 1948, supervisory test job; 1950, group engineer, operations; 1953 engineering group leader; 1955, section chief of engineering test. Using our refund plan, he has his M.Sc. in sight.

GEORGE P. SUTTON, in the 13 brilliant years since receiving his MSME. Cal Tech, has made rocketry a way of life. His reputation is world wide. His book *Rocket Propulsion Elements* is recognized as the standard text on the subject. Still active academically, but no bookworm, he takes time off occasionally to study the laws of motion at some of the world's better ski resorts.

Tomorrow's count down already fills the air at ROCKETDYNE's 1,600-acre Field Test Laboratory in the Santa Susana Mountains near Los Angeles. For this is the free world's largest workshop for rocket engineering—the great new industry that is now attracting many of the finest scientific and engineering minds in the country.

EXACTING RESEARCH, EXCITING PROSPECTS

From the rock-bedded test stands come 2 miles of recordings per day—data far ahead of available texts. The big rocket engine is a flying chemical factory in an absolute state of automation. It tolerates no error. It demands ductwork, turbomachinery, pressure chambers, orifices, injectors, heat exchangers and closed-loop control systems that must put hundreds of pounds of precisely mixed propellants into controlled combustion every second. Tolerances go down to 0.0001". Temperatures range from -250° F to 5000° F. Process time constants occur in "steady state conditions" of the order of a few milliseconds. Event sequences are minutely evaluated, as basis of designed performance predictions of extreme exactitude.

The methods now being developed at ROCKETDYNE for producing effective power to the limits of mechanical stress will have wide application. Such experience is practically unobtainable anywhere else. As a graduate engineer, *you* may be able to participate—now.

What motivates a rocket engineer? Well, the material advantages are high; but it is the work itself that draws him most. He feels the same incentive that moved Magellan . . . spurred the Wright Brothers . . . and beckoned again to Goddard as he flew the first liquid rocket at Auburn, Mass. in 1926.

At ROCKETDYNE, you can do this kind of pioneering in a management climate that stimulates personal growth—and rewards it to the limits of your ability. Academically, too, you can grow with our financial aid; some of the nation's finest universities are close by.

INTERESTING BOOKLET: "The Big Challenge"—facts on design criteria and development approaches used at ROCKETDYNE. Write for your personal copy, specifying your degree and years of post-college experience. Address: A. W. Jamieson, Engineering Personnel Dept. MAR, 6633 Canoga Ave., Canoga Park, California.

BUILDERS OF POWER FOR OUTER SPACE

BOURNS TRIMPOT®
MODEL 207 HI-R*

High Power—2 watts
High Resistance—100,000 ohms
High Temperature—175°C

The latest addition to the expanding line of Bourns TRIMpots is the new high power, high temperature, Hi-R.

The Hi-R will dissipate 2.0 watts at 50°C and has a maximum operating temperature of 175°C. Model 207 is available in total resistances of 100 ohms to 100K; Model 208, the variable resistor counterpart, is offered in 100K, 150K and 200K. High resistance values are combined with the excellent temperature coefficient and stability of a wirewound resistance element.

In addition to these many outstanding features, the Hi-R is miniature in size: only 3/32 x 13/16 x 1¼—0.28 cubic inches. The 25-turn adjustment shaft is self-locking, thus insuring stable settings under extreme conditions of shock, vibration and acceleration.

Delivery from stock on standard resistances. Send for Bulletin 207.

Notable Achievements at JPL

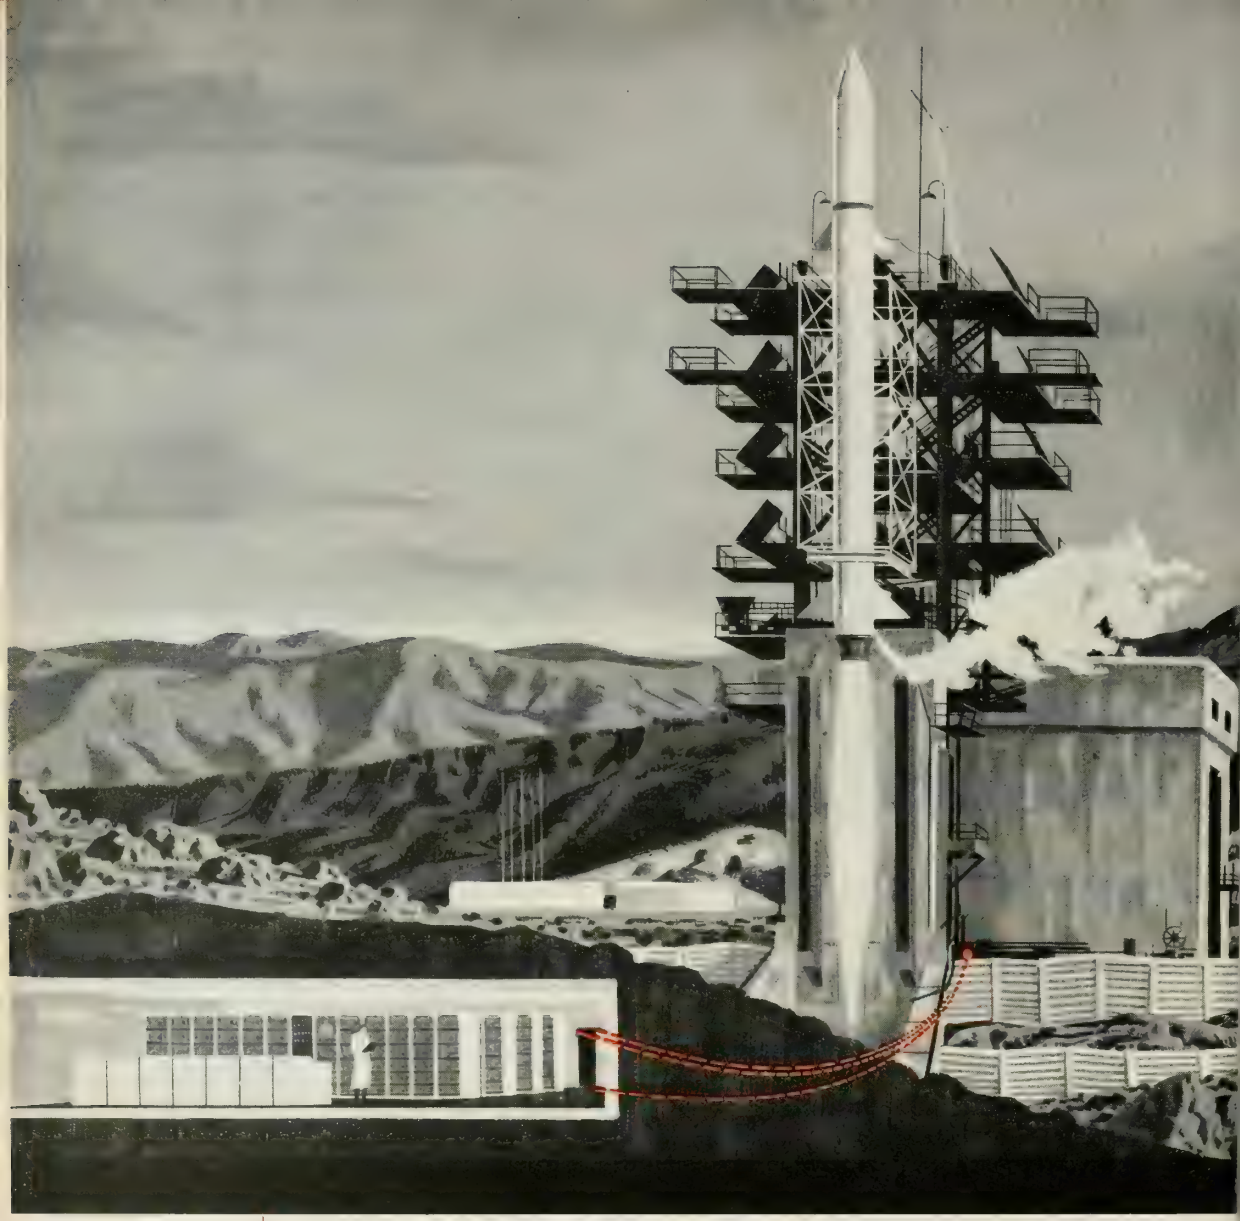
REALISM IN VIBRATION... Recognizing that it was necessary to provide a simulated missile-flight vibration environment far more realistic than heretofore available the Laboratory developed high power, wide-band, complex waveshape vibration testing equipment.

This has made possible the development of components and packages of greatly improved reliability.

New Techniques for Component Reliability

Wide-band, complex waveshape vibration testing using electromagnetic shakers driven by large audio amplifiers, is a valuable new tool for evaluating guided missile components. Input information can be in-flight vibration data which has been obtained via telemetering or it can be artificial vibration records sythensized from noise, pulses, sine waves, etc., to suit specialized needs.

Design and test for survival in adverse environment is fundamental in producing guided missile components with reliability adequate for modern weapons system requirements. At JPL, a constant search is being conducted for better design and packaging techniques, and for more significant laboratory test methods. Development of the "complex wave" vibration test philosophy, and of apparatus to exploit it, are but two results of this program. In the area of component design, new packaging techniques have been developed, involving control of local internal resonances and nonlinearities, which permit electronic circuits to withstand many times the vibration level which would destroy a conventional package.



Engineers and scientists are working at JPL in nearly all of the physical sciences. Here they are supported not only by outstanding laboratory facilities, but by a continuing series of experimental rocket firings which provide an invaluable tool for research and development.

The combination of a broad base of fundamental research, active development effort, and strong test and flight program has made the Lab a place of achievement. Perhaps you would like to participate in the many new, exciting programs now under way here. Your inquiry is invited.

BREEDS OPPORTUNITY at **BELL**

BELL AIRCRAFT IS A FAST MOVING, dynamic organization. Imaginative solutions to challenging problems and dramatic progress and accomplishments in many fields are its stock in trade. And because Bell is growing and progressing, it offers unusual career opportunities for the engineering and technical personnel listed at the right—opportunities at all levels to move fast and go far with highly capable associates in congenial surroundings.

Thanks to Bell's wide diversity of interests, you'll find the broadest possible scope for professional growth and the development of your talents at Bell. If you're bored with your present assignment or limited in your opportunities to grow, contact Bell.

Write: Manager, Engineering Personnel, **Dept. U, BELL AIRCRAFT CORPORATION, P. O. Box One, Buffalo 5, New York.**

- Low moisture absorption
- Translucent
- Solder heat resistance 450°F
- Watermarked for quick identification
- Sheet sizes up to 36″ x 96″
- Thickness from 1/32″ to 1/4″

New Formica Cirprint is far superior to any XXP ever made. The latest product of Formica-4 research, it offers a combination of properties useful in many military applications.

Check these outstanding Cirprint properties against your requirements:

High IR: 250,000 megohms after 96 hours at 35° C and 90% relative humidity.

Cold punching: up to and including 1/16″.

Moisture resistant: 0.80% in 1″ x 3″ x 1/16″ sample after 24 hours immersion.

Cirprint watermarking gives quick, positive, visual identification. Eliminates costly and ineffective factory records and marking systems.

You can *see* the quality because Cirprint is translucent. Its smooth structure is free of all impurities. Translucency also permits a visual check on the register of circuits printed on opposite sides of a sheet.

Evaluate the contribution Cirprint can make to your military electronics. Send today for free bulletin 755. Use the handy coupon below, or write Formica Corporation, subsidiary of American Cyanamid, 4533-7 Spring Grove Ave., Cincinnati 32, Ohio.

How Good the Russians?

The editors of this magazine have assembled in this issue more information and data about the Soviet Union's missile activities than have ever been collected in one public place before.

There are many pieces missing as is the case of every enterprise in Russia, especially military. Yet a fair amount is known.

What does it all add up to?

There is no evidence whatever that the Soviet Union has attained (as of now) an over-all superiority or even a measure of equality.

But the evidence is powerful that Russia is striving with all-out effort—and top priority—in the missile field. This is sufficient warning in itself from the greatest imperialist nation in the history of the world.

Three of this country's top military leaders have spoken out recently on the subject of the Red war machine.

Army Secretary Wilber N. Brucker quoted with telling effect Khruschev's pickled comment at a Moscow embassy party, "History is on our side. We will bury you."

Navy Assistant Secretary Garrison Norton urged strongly the continued modernizing of the Navy with missiles if this service is to keep pace with Russian development.

But it was left to General Bernard A. Schriever, Chief of the USAF Western Development Division, to add a reasoned appraisal to his warning of Soviet progress.

General Schriever said the question of whether the U.S. or the U.S.S.R. has the biggest and best ballistic missiles is somewhat like weighing the chances of the participants in an automobile race solely on the basis of their cars instead of considering the training and experience of the drivers, the reliability of their equipment, the support they receive in the pits, and similar factors.

We like that appraisal. The quality of the missile alone is not the decisive factor. As General Schriever said, there must also be know-how and organization for major strategic operations in order to create a real long-range missile capability.

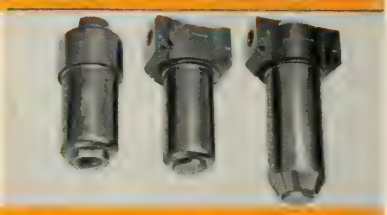
Once ICBMs and IRBMs are added to the inventory of the Strategic Air Command—whose capability and record is unquestioned—"There will be no over-all ballistic missile capability like it in the world."

Such confidence is heartening. But it is warranted just so long as this country keeps missile development in high gear.

WAYNE W. PARRISH

4-POINT FILTRATION

SPEEDS MISSILE DELIVERIES



PERMANENT FILTER BULK FILTRATION OF HYDRAULIC FLUIDS ON DELIVERY, IS FIRST STEP.

PERMANENT FILTER IN-LINE UNITS PROTECT HYDRAULIC MECHANISMS DURING MANUFACTURE AND PRODUCTION TESTING.

PERMANENT FILTER UNITS ARE REMOVING THE REMAINING CONTAMINANTS AS FLUIDS ARE DELIVERED TO FINAL SYSTEM.

PERMANENT FILTER OPERATIONAL UNITS PROTECT HYDRAULIC SERVO-MECHANISMS, SUCH AS THE CADILLAC GAGE FC-2 SERVO-VALVE, FOR SUCCESSFUL FLIGHTS.

PERMANENT FILTER Sintered Bronze Units Prove Reliability in Complex Aviation Problems*

The hydraulic fluid filtration problem faced by a leading aircraft and missile manufacturer was solved by the use of Sintered Bronze filters at the point of original delivery, in all critical hydraulic equipment within the plant, in the field hydraulic charging units, and in the missiles themselves.

Their inspection records showed the average inspection-rejection rate was 45 to 47% for the eleven months from January to November 1953; during February and March 1954, all paper filter elements were replaced with Permanent Filter Sintered Bronze units; from February to September 1954 the average inspection-rejection rate was 5 to 7%; and from January to April 1955, the average inspection-rejection rate was only 2 to 4%.

This is one of many case histories in which Permanent Filter installations have drastically reduced costly rejections and delays. As a result, Permanent Filter Sintered Bronze units are standard equipment on such missiles as the Nike, the Navajo, the Falcon, and on such combat aircraft as the F-100, F-104, F-7-U, F-8-U, and the RB-66.

If you have filter problems, such as fuel, hydraulic oils, gases, liquid nitrogen or liquid oxygen, Permanent Filter can answer your needs.

**Permanent Filter Sintered Bronze filter elements are available in variable micronic filtration ranges. These units are capable of operation in many different types of systems, ranging from such extreme temperatures as −350°F. to +750°F.*

Write or wire today to Department MR 2-7 for complete information and new catalog.

The most important announcement

in modern oscillograph history...

the dramatic new Honeywell direct-recording

VISICORDER®

All at once you can *record* and *read the record* of the Visicorder. Using a completely new direct-recording principle, the Visicorder puts six channels on a direct-reading record at sensitivities comparable to photographic oscillographs, and at frequencies from DC to 2000 cps!

HONEYWELL

VISICORDER® APPLICATIONS

The versatile Visicorder will fit almost unlimited applications because of its high frequency and sensitivity characteristics, and because of its ease of operation.

In any application where instantaneous monitoring is needed, whether or not a record is desired, the Visicorder is ideal.

★ **In CONTROL** applications the Visicorder will continually monitor and record reference and error signals, and present an immediately available recording of information.

★ **In NUCLEAR** applications, the Visicorder will monitor and record temperatures, pressures, and all other phenomena needed.

★ **In PRODUCTION TEST** applications, the Visicorder will provide a final dynamic inspection of electrical and mechanical devices such as motors, relays, generators, governors, solenoid valves, etc., where high frequency response has been required, but unavailable in the past.

★ **In COMPUTING** applications, the Visicorder will provide immediately-readable analog recordings representing dynamic solutions at much higher frequencies than have ever been available via pen—and-ink-type recorders previously used for this work.

★ **In PILOT and COMPONENT TESTING,** the Visicorder will accomplish more rapid evaluation of design and prototypes than any other direct-writing oscillograph available.

★ **In MEDICAL** applications the Visicorder is useful for dynamic blood pressures, electrocardiograms, EEG, and other physiological measurements.

★ **In all TEST** applications the direct-recording features of the Visicorder are invaluable. Where complex tests involve the assembly of considerable equipment and the gathering of personnel, the immediate Visicorder record will prove the success of the test at once before the test equipment is dispersed.

For further information about the Visicorder, contact the Minneapolis-Honeywell Industrial Division Sales Office nearest you. Sales-service facilities in over 130 principal cities throughout the world.

Radiation Pressure

To the editor:

. . . In a letter "Radiation Pressure" in your December issue, Mr. Norman Blubaugh obviously refers to the Crooke's Radiometer as the revolving element actuated by "light pressure."

It is astonishing that this fallacy of "light pressure" is still fostered; one wonders about the efficacy of physics teaching in this country which does not more clearly demonstrate the absurdity of this premise.

The Crooke's Radiometer is based on the principle of a differential pressure across each vane. The shiny side of each vane is cooler than the black side. Therefore the pressure (in the *partial* vacuum of the bulb) adjacent to the black side is lower than that next to the cool side.

Thus a net force results and pushes the vanes in the direction of the black side. As the radiometer bulb is exhausted to a harder vacuum, the vanes now turn in the opposite direction, with the shiny side turning toward the light. This is caused by the, by now imperfect gas, behaving as discreet particles; these particles when heated by the black side increase their motion and impinge on the black side and transfer their momentum to the black side thus pushing the vanes away from them, that is, i. e., with the shiny side leading.

If the vacuum is reduced to a very low level of pressure then the vanes do not turn at all, no matter how much light impinges upon them. The actual light pressure in micro-micro dynes is immensely less than that required to move the vanes. It is true that a powerful enough light source could produce a motion of the vanes but such a light beam would vaporize the entire radiometer.

As for "sunlight pressure" navigation in space, reflective "sales" of hundreds and thousands of square miles of surface area should be required to propel a vehicle of even a low mass. Furthermore, the light's pressure falling off as the inverse of the distant-squared from the sun further complicates the picture . . .

Kurt R. Stehling
Propulsion Head
Naval Research Laboratory
Washington 25, D. C.

Satellite Camera

To the editor:

. . . After reading Henry Steier's article in the January issue on the satellite tracking cameras, I thought you might be interested to know that the optical systems for the cameras will be one of the most difficult optical production jobs ever attempted. I don't think anything quite like it has been tried before on a production basis.

As you know, the optical design calls for a 31-inch mirror, and three aspheric corrector plates. Until Perkin-Elmer developed economic production methods for aspherics, making such elements of this order were pretty much a hand-made proposition. Generating the aspheric surfaces for these systems will be all the more difficult because of the thickness of the glass, which is so small in proportion to its diameter.

Aspheric surfaces, as you may know, take the form of paraboloids, ellipsoids, hyperboloids or other geometric forms that can only be defined by complex equations. Their advantage to lens design is twofold. First, since an aspheric surface often replaces one or more classical surfaces (spheres or flats), it means lighter weight and smaller lenses. Secondly, aspherics will sometimes correct for aberrations not otherwise correctable, resulting in faster and more precise lens systems . . .

Charles C. Dayton
Public Relations
The Perkin-Elmer Corporation
Norwalk, Conn.

To the editor:

. . . We were very pleased to see from the January issue, on page 64, the description of the Vanguard satellite tracking camera.

You will be interested to learn that the three element Schmidt type objective, consisting of two KzFS-2 and one SK-14 discs of 22″ diameter, was supplied by us and produced by the world-renowned Jena Glass Works of Schott & Gen. in Mainz, West Germany, whom we represent. The optical design was, as noted by you, prepared by Dr. James G. Baker. This glass was found to produce an image with very much reduced secondary spectrum.

We trust that you can make mention of this in your magazine . . .

Murray Yawitz, President
Fish-Schurman Corporation

New Rochelle, New York

Name-Change

To the editor:

. . . I should like to call your attention to a mistake in the listing of Subcontractors Guide: "Missile Electronics and Astrionics" which appears in your January issue. On page 79 the name Raymond and Rosen Engineering Products appears. This should be listed as Tele-Dynamics Inc. so as to reflect the name change of our organization which took place on August 1, 1956 . . .

Rocket Producers

To the editor:

I was most interested in your article on the "Mighty Mouse" in the November issue and noticed that two of the Rocket Head manufacturers had been omitted from your list of "Well Done" manufacturing facilities.

Since the current issue has not corrected the situation, I'll have to wave the flag for two of the finest cooperating military producers in the business; namely, Hubeny Brothers, Inc., Roselle, New Jersey, and John E. Mitchell Company, Dallas, Texas . . .

Giannini Trim-servo System specified for Convair F-102A... wide range...high altitude...sensitive

The development of Century Series Aircraft has greatly intensified the need for Giannini precision instruments and systems to simplify the increasing complexities of high speed, high altitude flight. An outstanding example is the Giannini functional Mach computer for the elevon trim-servo system which enables the Convair F-102A all-weather interceptor to maintain subsonic trim characteristics at supersonic speeds.

The trim-servo system, a highly accurate Mach number and altitude sensing-computing system which reacts to speed changes as small as 0.0005 Mach, is one version of the servoed bridge network computing systems previously designed and developed by Giannini avionic engineers. The basic design has such capability and flexibility that a prototype computing system was produced for Convair in less than three weeks. Delivery of the first production model was made in less than two weeks from date of purchase order.

This rapid design and development is one more instance of Giannini's superior performance in the engineering and production of quality airborne equipment.

Engineering positions are open at several Giannini locations for career-minded young men—write for details.

When you need to know the "score"...

AMF has experience you can use

● A supersonic missile, even though out of sight, is never "out of mind". The commander directing the attack must know how effectively the missile performed its mission of destruction. And intricate AMF feed-back equipment tells him—sending an automatic report-card from launching to final target "kill". ● Keeping tabs on the flight of a missile is but one of the hundreds of complex tasks AMF performs every day. The highly specialized yet widely diversified activities of some 35 engineering and production facilities provide AMF with a wealth of experience that covers nearly every field of industry. And it is immediately available to you. ● Call upon AMF with your problem. See for yourself why this all-around experience in answering the needs of government and industry alike has made AMF a "can do" company.

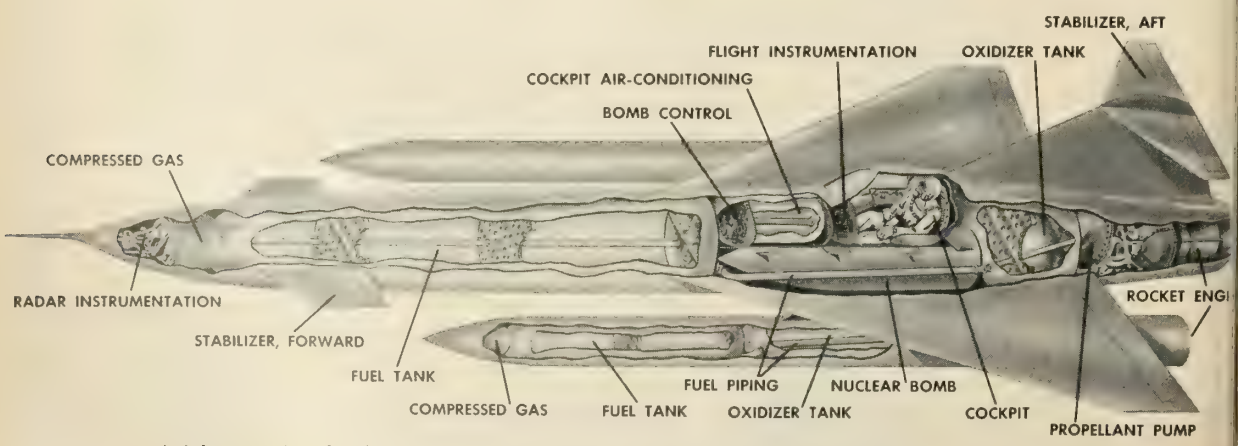
Manned Rocket Bombers Underway

Soviet and U. S. Enter Race For Space Craft Of 10,000 Mile Range

By Erik. Bergaust



The Soviet and US now are believed to be entering a red-hot race for the next step in ultra-modern warfare. What comes after the ICBM? The answer, according to several experts, is the manned space-rocket bomber, an entirely different concept in weaponry and the greatest technological challenge yet. This supercraft supposedly is a missile with a man it, designed to cover distances up to 10,000 miles. Several US companies have expressed interest in the project, and it is safe to assume that study contracts have been awarded. Among the companies mentioned in this connection are Convair and Bell.

The Soviets have shown great interest in manned space bombers ever since the end of World War II. In fact, the reds tried to pursuade Dr. Eugen Sanger, designer of the antipodal bomber, or skip bomber, to go to work for them. Dr. Sanger, turned down the offer, whereupon the Soviets tried to kidnap him. However, Dr. Sanger is safe in Stuttgart, where he heads up a jet propulsion institute and is working on such advanced projects as ion rockets.

The antipodal bomber concept was conceived by Dr. Sanger during the last war as a possible solution to direct bombardment of targets on the United States mainland from launching sites in Europe. The manned missile would be launched into areopause altitude, approximately 120 miles up, and then behave like a ballistic missile, i.e. it would decend back toward earth in a ballistic path. However, hitting the denser layers of the atmosphere the missile's wings would provide "lift" and bounce the vehicle up into thinner atmosphere layers again, aided by bursts from the rocket engine. It has been calculated that only three of these bounces would be necessary for the bomber to cover the distance from Europe to the United States.

When Dr. Sanger's glide-and-rocket bomber was revealed after the war, many experts could not help being skeptical about the concept. But these same experts seem to think differently today. Although the forthcoming space bombers may or may not be skip-or antipodal vehicles, the feasibility of sending a manned space rocket craft over a distance of 10,000 miles is obvious. It seems, however, that it will take at least two or three years to develop a rocket bomber prototype, if work on it got underway today. And, in all probability, both the Air Force and Navy would want to gather some experience with the high-altitude research aircraft now being built before attempting to design the bomber.

Reports gathered for this issue of m/r indicate the Russians have been working on an advanced version of the Sanger craft, and that its designation is T-4A. A manned as well as an unmanned version are believed to have been attempted. Some of the reports

Artist's conception of Red rocket bomber that would climb to 120 miles and cover a distance of 10,000 miles.

indicate the manned version will be track-launched and that it could cover the distance between Leningrad and New York in 89 minutes.

We are rather skeptical about any statement to the effect that the Russians have advanced to the hardware stage in manned rocket bomber development, but, as has often been proven, it is quite probable that they are on a par with us in this field as well.

Adding up the information we have obtained on the Red rocket bomber, it appears their super craft would be between 60 and 70 feet long. It would be fitted with three liquid rocket engines, all burning kerosene and liquid oxygen. The two smaller, wing-mounted engines and their tanks and turbine gear will be jettisoned after burnout during the initial climb to 120 miles. The vehicle also will employ a large-size booster for the run along the rails or tracks that supposedly will be used for takeoff.

The ship have a delta-wing and T-tail stabilizer. Fuel tank is located in the main fuselage section forward of the cockpit, oxidizer tank is directly behind pilot. Bomb compartment is directly underneath the cockpit.

US Air Force planners—naturally—have no comments to offer on our own efforts in the field of manned space-rocket bombers, but many industry officials believe the Air Force is about to undertake "something big" and "real sophisticated" in this field. Funds for whatever work is being done now probably come from R&D grants.

According to the Italian aviation publication "Alata" this is the way the Russians contemplate to launch their rocket bomber. Bomb is to be dropped on New York. Pilot will be picked up by sub in the Pacific.

IRBM, ICBM Get Super-Priority

HUNTSVILLE, Ala.—Officials of the Army Ballistic Missile Agency and Redstone Arsenal have received notification that the U.S. Department of Commerce has assigned top priority to the IRBM and ICBM research and development programs. The order will specifically affect work on the *Jupiter*, the Army's intermediate range ballistic missile. Supposedly, the *Jupiter* prototype is being readied at Patrick AFB for firing. The order also applies to USAF and Navy programs in the same fields.

The top priority will be helpful to contractors in the procurement and purchase of scarce materials and components. It applies to them and to all others engaged in research, development and production of the weapons.

This is the first time that the super-priority has been applied to programs of the IRBM and ICBM scope.

Russians Hold IRBM Lead?

Moscow now seeks to confirm what some American scientists have been saying privately for some time—that Russia is leading the United States in some significant categories of guided missile development.

Pravda, the official Communist party newspaper, had this to say the other day:

"It is common knowledge that the United States is far from being a monopolist e i t h e r in the sphere of nuclear weapons or, even less so, in the sphere of long-range missiles.

"Here it would be more appropriate to talk of America's lag."

The jibe at American missile technology was contained in a lengthy Soviet warning to o t h e r countries against p e r m i t t i n g establishment of U.S. atomic military contingents on their territory.

The warning included the threat of nuclear retaliation by the Soviet Union, possibly by missile delivery, in the event of war.

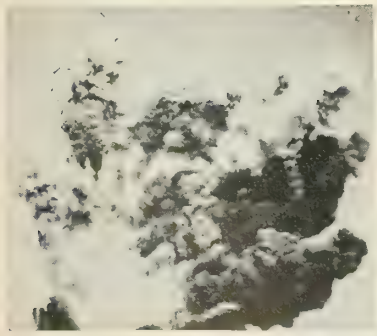
Pravda said that the U.S. Defense Department "intends to station atomic groups armed with the latest types of guided missiles in troubled areas."

And it quoted from President Eisenhower's budget message references to increasing the number and variety of nuclear weapons and a 35 per cent increase in guided missile expenditures.

"How can these aggressive plans be reconciled with the dulcet speeches of (Henry Cabot Lodge) U.S. representative to the United Nations, who urged the world the other day to abandon the tendency of stockpiling atomic weapons, to reduce the atomic threat in the future, to bring about a situation where scientific research in the sphere of jet-propelled missiles would be devoted to peaceful scientific purposes," *Pravda* asked.

State Department officials refused to take too seriously the Soviet threats against our allies.

But they, together with Pentagon planners, wondered precisely what the Reds have under development to back up the boast that the U.S. is lagging in long-range missile development.



While the Russians claim they have plenty IRBMs and while reports say they are equally advanced in the field of ICBM development, the United States is in position to show off an actual piece of ICM hardware—and a production model at that: Northrops SNARK.

$533 Million More for Guided Missiles

Six Billions to be Spent in Next Two Years . . . Research and Development Grants Cut

Army has released photographs of its field weapon Lacrosse. Development of this weapon has highlighted accuracy and mobility, according to the Army. These pictures also indicate striking power. "The Lacrosse is a deadly accurate guided missile for close tactical support of ground troops in the field," Redstone spokesmen said. It is mounted on a mobile launcher. First pictures show several of the missiles mounted on the launchers which was taken to indicate that Lacrosse is in at least small quantity production and that field units are being trained in its use.

The Defense Department will spend more money for guided missiles in the 12 months beginning July 1 than ever before in history. New orders for missiles will be second only to the current fiscal year.

According to Wilfred J. McNeil, Assistant Defense Secretary (Comptroller), the Army, Navy and Air Force will spend $2,039,000,000 for missiles of all categories during fiscal 1958 and will have an additional $2,563,000,000 available for missile procurement during the same period.

President Eisenhower's budget for 1958, which calls for $38 billion in new money and $38.5 billion in expenditures for the Defense Department, indicates that "expenditures for guided missiles will be up 35 per cent" during the coming year while procurement of manned aircraft will remain at about the same level and ship construction will be up 12 per cent over fiscal 1957.

The Pentagon comptroller provided the following comparisons of missile expenditures and money available for missile obligations over an eight-year period. The figures include all of the military services.

Defense Department Guided Missiles

	Expenditures	Available for Obligation
Fiscal 1951	$21,000,000	$424,000,000
Fiscal 1952	169,000,000	468,000,000
Fiscal 1953	295,000,000	896,000,000
Fiscal 1954	504,000,000	748,000,000
Fiscal 1955	718,000,000	345,000,000
Fiscal 1956	1,168,000,000	938,000,000
Fiscal 1957 (est.)..	1,506,000,000	2,300,000,000
Fiscal 1958 (est.)..	2,039,000,000	2,563,000,000

McNeil indicated the new money being requested would enable the Air Force to finance either the Chrysler *Jupiter* or the Douglas *Thor* 1500-mile-range ballistic missiles but not both. The same, he added, is true of the Army, which will have to decide between the Douglas-Western Electric *Nike Hercules* and the Bendix *Talos* surface-to-air weapons to replace *Nike Ajax*.

The Defense Department's budgetary expert gave the following indications of missile expenditures and available money for each of the services during the 1951-58 period.

Army Guided Missiles

	Expenditures	Available for Obligation
Fiscal 1951	.....	$173,000,000
Fiscal 1952	$46,000,000	253,000,000
Fiscal 1953	119,000,000	301,000,000
Fiscal 1954	187,000,000	225,000,000
Fiscal 1955	238,000,000	.....
Fiscal 1956	333,000,000	.....
Fiscal 1957 (est.)..	425,000,000	.....
Fiscal 1958 (est.)..	562,000,000	425,000,000

Navy Guided Missiles

	Expenditures	Available for Obligation
Fiscal 1951	$5,000,000	$130,000,000
Fiscal 1952	56,000,000	119,000,000
Fiscal 1953	95,000,000	181,000,000
Fiscal 1954	141,000,000	159,000,000
Fiscal 1955	176,000,000	126,000,000
Fiscal 1956	195,000,000	238,000,000
Fiscal 1957 (est.)..	221,000,000	352,000,000
Fiscal 1958 (est.)..	264,000,000	428,000,000

Air Force Guided Missiles

	Expenditures	Available for Obligation
Fiscal 1951	$16,000,000	$121,000,000
Fiscal 1952	66,000,000	95,000,000
Fiscal 1953	81,000,000	414,000,000
Fiscal 1954	176,000,000	364,000,000
Fiscal 1955	305,000,000	219,000,000
Fiscal 1956	641,000,000	700,000,000
Fiscal 1957 (est.)..	860,000,000	1,948,000,000
Fiscal 1958 (est.)..	1,213,000,000	1,710,000,000

President Eisenhower's budget message shows that the total new money request for missiles in fiscal 1958 is $2,646,000,000. This sum includes $425 million for the Army, $428 million for the Navy and $1,793,000,000 for the USAF.

McNeil reports that if this new obligational authority is voted by Congress, the sum will be coupled with carryover and other funds and will result in new direct obligations during fiscal 1958 of $2,828,000,000 for missiles. The $2,828,000,000 will include direct orders by the Army for $673 million, by the Navy for $465 million and by the Air Force for $1,690,000,000.

Direct obligations figure, compares this way for the 1956-1958 period.

Direct Obligations for Missiles

	FY 1958	FY 1957	FY 1956
*DD	$2,828,000,000	$3,071,000,000	$1,630,000,000
*A ..	673,000,000	743,000,000	439,000,000
*N ..	465,000,000	440,000,000	222,000,000
*AF	1,690,000,000	1,888,000,000	969,000,000

*DD—Defense Dept.
*A—Army
*N—Navy
*AF—US Air Force

McNeil declares that there will actually be an increase in obligations for missiles between fiscal 1957 and 1958, if the ballistic program is discounted. Across the board, he says, more missiles are to be ordered in the coming year. The more than $3 billion scheduled to be obligated during the current fiscal year includes much of the initial groundwork for the IRBM (*Jupiter* and *Thor*) and the ICBM (Convair *Atlas* and Martin *Titan*) program, and will inevitably drop off in 1958, McNeil states.

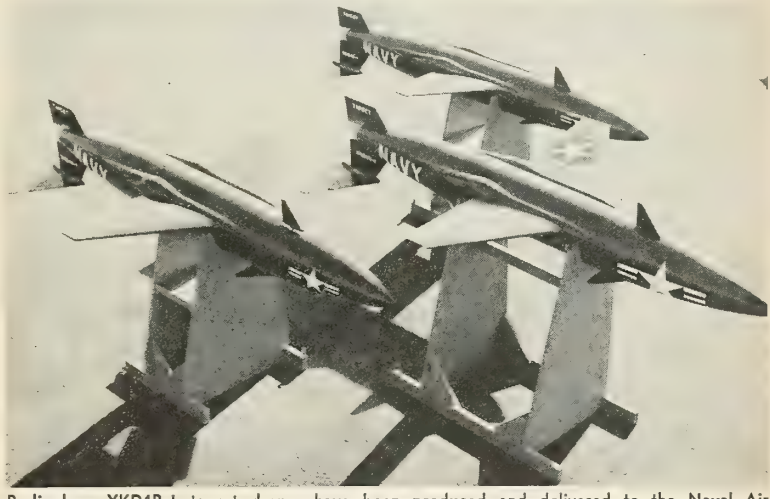
On the research and development side, the Presidential budget message indicates a total of $331,800,000 is to be obligated in fiscal 1958 by the three services for "guided missile and related equipment" R&D. The respective figures for 1957 and 1956 are $346,500,000 and $280,400,000.

Isolation of the R&D activities in the guided missile field by the Army, Navy and Air Force shows the following comparison:

Research and Development (Guided Missiles and Related Equipment) Program and Financing

	Army	Navy	USAF
Fiscal 1956	$111,953,992	$95,226,874	$73,279,983
Fiscal 1957 (est.)..	108,985,000	146,219,035	91,327,081
Fiscal 1958 (est.)..	87,380,000	167,963,000	76,412,000

It becomes readily apparent that some guided missiles in the research and development stage in 1956 and 1957 are to be funded out of procurement money for 1958.



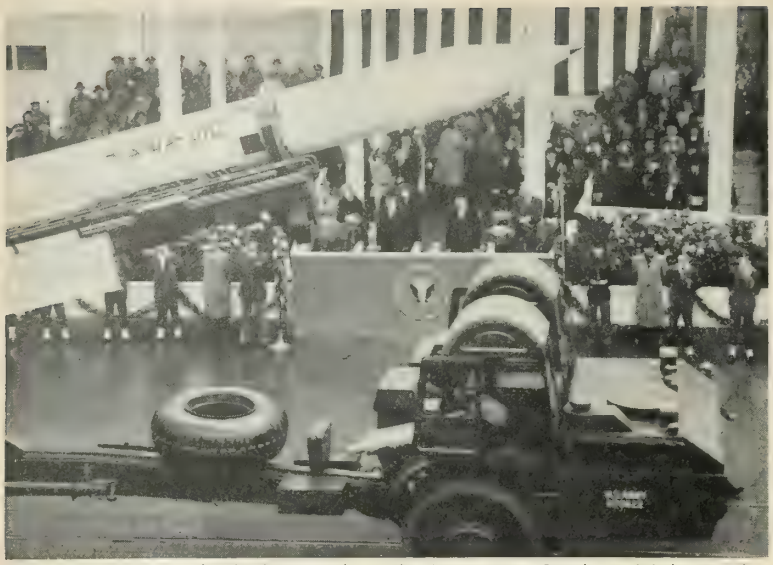
- The Army's missile R&D money shows a $21.6 million drop between 1957 and 1958. Its direct obligations for missiles also will decrease $70 million during the period. Spending will climb by $137 million.
- Navy R&D activities in the missile field rise by $21.7 million (presumably to cover the ship-based *Jupiter* IRBM and the sub-based *Polaris*, among others) and its direct obligations will climb by $25 million between 1957 and 1958. Spending will rise by $43 million.
- USAF missile research will fall off by $14.9 million and its direct obligations also will be down by $198 million. Spending will be up by $353 million.

Summarizing the 1958 Defense Department figures as a whole:

- Missile R&D will be down $24.8 million from 1957.
- Direct obligations for missiles will decrease by $243 million.
- Spending for missiles will rise by $533 million.

Sleek X-10 NAVAHO test missile built by North American. This is our second intercontinental missile, Northrop's SNARK being the first one—and closer to production.

Radioplane XKD4R-1 target drones have been produced and delivered to the Naval Air Missile Test Center at Point Mugu, California. The missiles are built under a Navy contract.



Biological Research In Satellites?

A committee of the Space Medicine Association has been formed to plan for biological and medical experiments in the U.S. earth satellite program. The committee, chaired by the Association's President, Dr. Fred A. Hitchcock of Ohio State University, has as members, four leading space medical investigators: Dr. Hubertus Strughold (USAF Department of Space Medicine, Randolph Field), Dr. Heinz Haber (University of California), Dr. (Major, USAF) David G. Simons (Holloman AFB), and Dr. Hermann Schaefer (NAS, Pensacola).

None of the physical experiments contemplated for the U.S.-IGY satellite program are in the fields of biology or medicine. The function of the Association's committee will be to plan a "definite and worthwhile" research program so that space medical researchers will be ready when space and weight are allotted for such experimentation aboard future satellites.

Queried as to Russian interest in such matters, one member of the Association commented that he "wouldn't be surprised" to see such experimentation "early" in the Russian satellite program. "We all know we'll be experimenting in that medium eventually, and I think the Russians would like to be first," he stated.

The Space Medicine Association is a subsidiary organization of the Aero Medical Association, the professional society of aviation physicians and flight surgeons.

Guided missiles gave the finishing touch to the Inauguration Parade in Washington last month. The Army managed to raise the Corporal—in salute—as the launching van passed the presidential stand.

Lockheed proudly displays its X-17 re-entry test missile. Vehicle is said to have made numerous successful flights. Note bulky spin stabilizer rockets mounted on first stage.

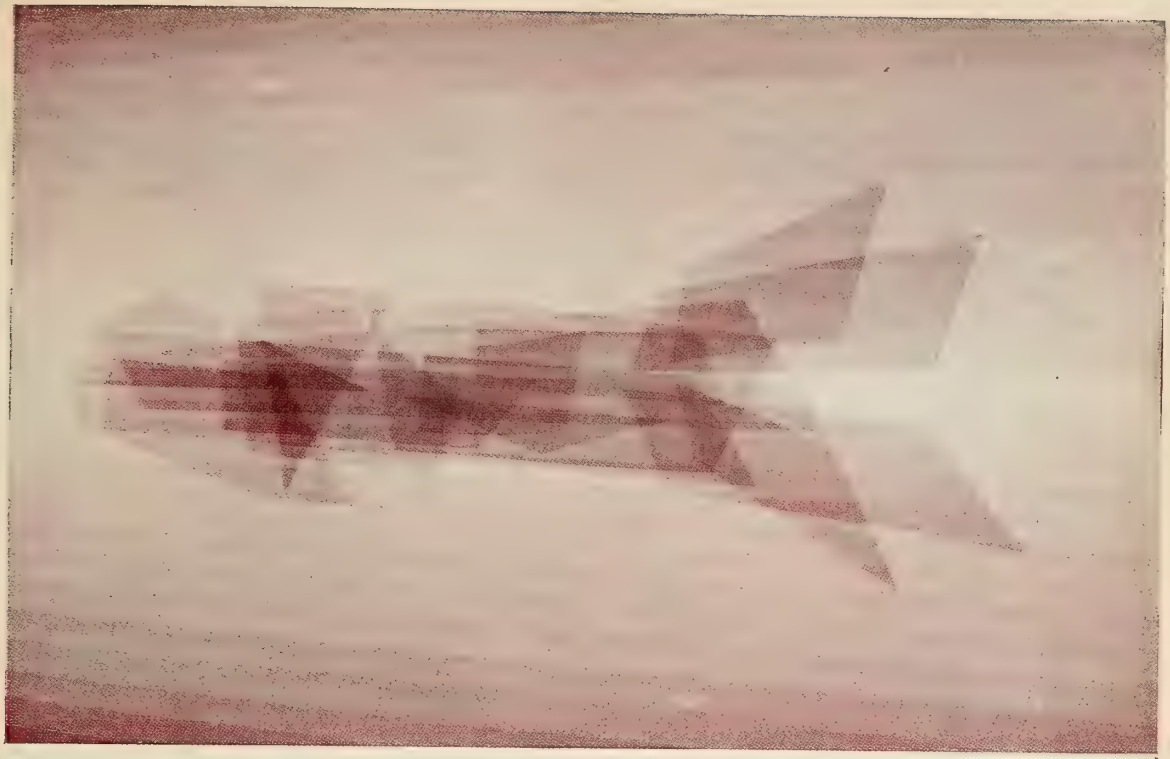
Big ARS Meeting In Washington This Spring

The Nation's capital will be the scene of the National Annual Spring Meeting of the American Rocket Society. Illustrated lectures on space flight, earth circling objects, and rocket vehicles will be presented.

The national meeting will be held at the Sheraton Park Hotel, Washington, D. C. April 3 to 6, 1957. More than a thousand experts are expected to be on hand.

One of the principal features of the Spring Meeting will be the exhibition of physical objects and displays staged by the American Rocket Society on rockets, guided missiles, satellites and concepts of space ships—including their components, materials and accessories.

Expected to be included in the exhibit are actual guided missiles, full scale rocket and ramjet engines, a prototype of the *Vanguard* satellite, instrumentation and guidance equipment for missiles, telemetering apparatus, tracking systems, data reduction equipment, and many accessory and component items. Companies interested in booth space should contact ARS in N.Y.



The Spring Meeting was originated by Erik Bergaust, President of the National Capital section of the American Rocket Society and Managing Editor of MISSILES & ROCKETS. Meeting Chairman is Andrew G. Haley, formerly National President of the American Rocket Society and for several years Vice-President of the international Astronautical Federation. Chairman of the National Program Committee is Kurt R. Stehling.

Luncheon speaker and the chairman of the April 4 afternoon session is Doctor Theodore von Karman.

Throughout the sessions, similar renowned experts will give papers, conduct illustrated lectures, and present breakfast and luncheon talks. Extensive program for ARS members' wives is planned.

The meeting will center around four principal themes, namely, Space Sociology, including Medicine, Law, Education and Economics; High Speed Rocket Test Tracks; Propulsive Systems; and the *Vanguard* project, including discussion of the progress of the International Geophysical Year.

More than 300 members of the International Society of Aviation Writers will meet in Washington at the same time. The writers will be invited to attend the ARS sessions. (See "People" page 118).

"ROCKETS", one of a series of paintings by Simpson-Middleman, a team of artists with the rare ability to translate scientific fact into creative imagery. Here, the rocket's blast and its guiding beam are thought of as a single stream of light through the center. Darks and lights of definite shape in a weak visual vector field are relied on to suggest the "wobble" caused by the acts of the servo-mechanisms in making their adjustments. Painting courtesy John Heller Gallery, Inc.

Invitation to sky-high adventure

At Boeing, advanced engineering and scientific minds are adventuring beyond the limits of the known. There's excitement here, and satisfaction for men of imagination. There is a welcome, too, for advanced ideas—and the aviation industry's widest array of research laboratories and electronic computing equipment to serve you.

If association with men of engineering and scientific vision appeals to you, get in touch with Boeing. There are exceptional openings at Boeing—now—for engineers of *all* types, and for advanced mathematicians and physicists. Assignments are long-ranged in such assured-future fields as supersonic flight, electronic guidance and related areas of discovery.

Drop a note now to John C. Sanders, Engineering Personnel Administrator, Boeing Airplane Company, Department R-60, Seattle 24, Washington.

BOEING

Now! Elemental Fluorine Available in Bulk . . . and in Easy-To-Use Liquid Form

GENERAL CHEMICAL Announces

TONNAGE SHIPMENTS OF Liquid Fluorine!

Large scale transportation of elemental fluorine is now possible and practical. This most reactive of all elements has been tamed and harnessed by General Chemical for industrial use . . . by anyone, anywhere . . . without requiring captive plant facilities.

As a result of General Chemical research, fluorine can now be stored, transported and handled directly *as a liquid in tank-truck tonnages.* Large quantities can be used with far greater economy, simplicity and safety than has ever been possible with the normally gaseous form.

If your production or research program involves fluorine or fluorine-supplying chemicals, look into General's liquid fluorine development without delay. It makes possible new approaches to your problems that were impossible before. As a first step, write today for our comprehensive new technical bulletin, "Fluorine." It contains a wealth of helpful data.

Huntsville Braces for ABMA Expansion Program

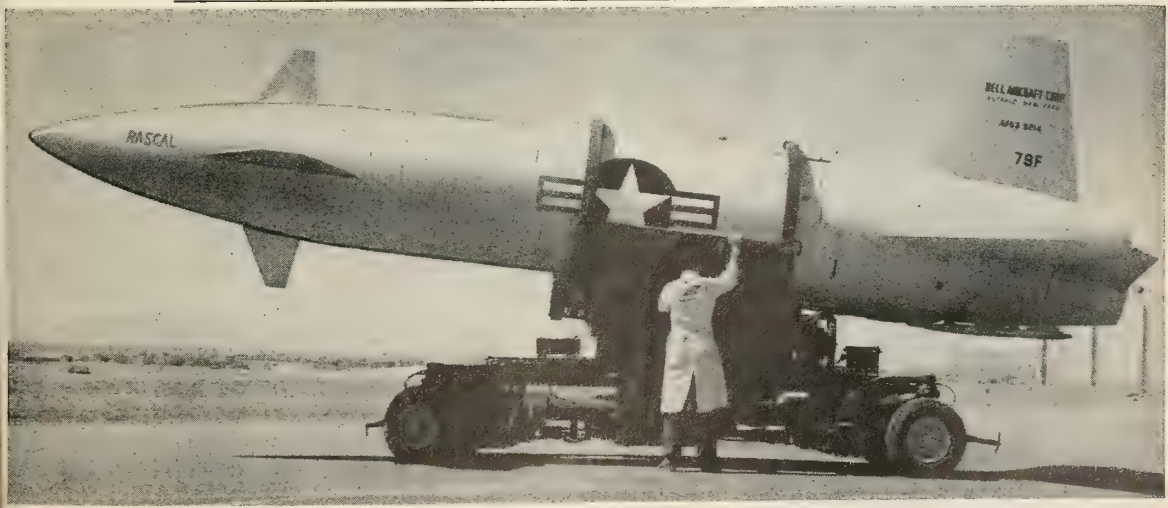
HUNTSVILLE, ALA.—The reported misfiring of the USAF *Thor* ballistic missile in its first tests at Patrick Air Force Base, Fla., had immediate repercussions in this city, home of Redstone Arsenal and the Army Ballistic Missile Agency where the *Jupiter* IRBM was developed.

Only a few hours before the report of the *Thor* fizzle was published, Maj. Gen. John B. Medaris, ABMA commander, made a strongly worded appeal to the annual dinner of the Chamber of Commerce for a broad program of civic expansion. His words acquired special significance in the light of the next day's announcement.

"There is more work to be accomplished in the missile field than there are people to handle it. Consequently, I see nothing but increased activity here for some time to come. We will have even greater responsibilities than ever before," he declared.

The Medaris speech came as a bracing tonic to the city which, under the impetus of Redstone and ABMA, has expanded from 16,000 people in 1950 to almost 60,000 today. The area had been fearful of cutbacks and wholesale transfers of missile and rocket personnel and equipment since Secretary of Defense Wilson issued his memorandum late in November giving the Air Force jurisdiction over all missiles with a range of more than 200 miles. Even the m/r story of November, giving first details of the highly successful first flight of the *Jupiter* and pointing out that full development of *Thor* would require another two years of intensive work did little to lift the gloom that had settled over the area.

Planning for expansion of the city's school, water, sewage and gas systems, which had been delayed when the Wilson memorandum was made public, has now been resumed. A program for some 750 new low-cost houses which also had slowed was stepped up. New tax rates are going into effect in both city and county to finance the expansion of services.



Medaris is repeating his prediction of a year ago that Huntsville will be a city of 100,000 persons by 1960, and the city believes this can only mean that there will be a huge expansion of work at the Arsenal and ABMA, with the Air Force coming in, even reluctantly, to benefit from the work of the famous von Braun group.

The impact of Arsenal and ABMA personnel upon the city was aptly illustrated recently when Hannes Luehrsen, a member of the group, proposed an ambitious plan for remodeling of the city's 150-year-old court house square to provide a magnificent two-mile mall and civic center through the very heart of the city, with parks and lagoons. Luehrsen once prepared similar plans for the city of Berlin. He was also a prime mover in planning of the new four-lane Memorial Parkway which now traverses the city and has sparked a new wave of commercial construction that is actually shifting the business center of the city to the super-highway. The new proposal was made public on one-half of the front page of the local daily.

Underlining the Medaris plea for adequate civic facilities is the fact that the Army since the Wilson memorandum has quietly been transferring large numbers of skilled personnel from other arsenals across the country to Huntsville. A group of 75 new people came in during one week in January from an Eastern arsenal, and applications for employment at the Arsenal have risen from the normal average of 1,250 per month to 2,000. Personnel directors say they expect no slackening of this tempo during 1957.

Indicative of the community's optimism is its reaction to the closing of one of its largest industries, a cotton mill that had functioned here for more than half a century. Only five years ago such a closing would have been a calamity. Now, however, the Huntsville Industrial Expansion Committee regards it as an opportunity for further growth. A group of local leaders now plans to purchase the mill and make its five buildings and 800,000 square feet available to new industries, with heavy emphasis upon those participating in the ballistic missile program. Most of the 700 textile workers made idle are being rapidly absorbed into other jobs.

Informed opinion seems to be that the Army, within the scope of the Wilson memorandum, is now concentrating more of its effort at Redstone and ABMA and will continue to do so; that there is now the chance that the Air Force will not be so reluctant to begin financing ABMA when the new fiscal year begins on July 1st; and that these developments foreshadow the buildup of a real missile and rocket production industrial complex that may make this one-time sleepy little Southern town truly "Rocket City, U.S.A."

Air Force has permitted Bell to release picture of the Rascal—after skilled artist eliminated sonar-type radome and reshaped the nose.

Sharp Criticism by Symington on U.S. Missiles

After a million words of testimony, Senator Stuart Symington's Air Force Subcommittee last month issued its report. Here follow excerpts from the conclusions of that report having to do with missiles and the Soviet threat.

"The vulnerability of the United States to sudden attack has increased greatly during the past decade and this vulnerability will continue to increase in the foreseeable future.

"The Department of Defense has failed to develop an adequate defense warning system.

"The direction and planning of naval strength again leaves the United States vulnerable to submarine attack against our shipping, and particularly vulnerable to submarine missile attack on military and civilian targets within our heartland.

"The Soviets are rapidly closing the qualitative gap. Yet, our qualitative lead is now being given as justification for our having passed over to the Soviets quantitative superiority in military airpower.

"The duplicating approach characteristic of many research and development programs in the Department of Defense, along with the dollar limitations established for such programs, has retarded needed modernization of weapons systems.

"These policies have retarded important scientific breakthroughs. They contrast with Soviet policies which have produced extraordinary Soviet progress in the research and development field.

"The Soviets exceed the United States in rate of technological development, in training facilities, in speed and quantity of prototype development, in the training of scientists and engineers, and in many other phases of airpower development.

"The Department of Defense has permitted duplication, even triplication, among the three services in the development and production of missiles; and has permitted comparable waste in the allocation to the three services of responsibility in the missile field.

"The Department of Defense also delayed in giving overriding priority to the ballistic-missile program. As a result, there has been a serious loss of time as compared with the rapid progress of the Soviets in this field.

"Financial considerations have often been placed ahead of defense requirements, to the serious damage of our airpower strength relative to that of Russia; and hence to our national security.

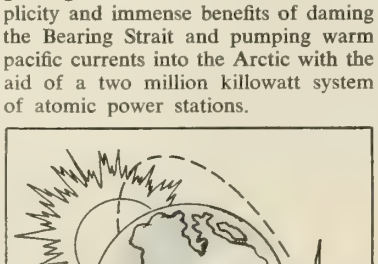
"The United States has the capacity to produce and maintain airpower which is relatively stronger than that of the Soviets; but the Department of Defense has not utilized this capacity.

"With proper programing and administration in the Department of Defense, it would be possible to maintain air supremacy over the Soviets without jeopardizing a sound economy and without imposing additional tax burdens upon the people.

"Under our form of government, the American people have not only the right, but also the need, to receive all information about our national defense which would not help a possible enemy. Nevertheless the public is neither adequately nor accurately informed about our military strength as against the great and growing military strength of the Communists.

"The public has failed to receive from official sources complete, accurate and timely information which it has the right to know.

"The subcommittee recommends that the deficiencies in military strength, as pointed out . . . be corrected as promptly as possible.



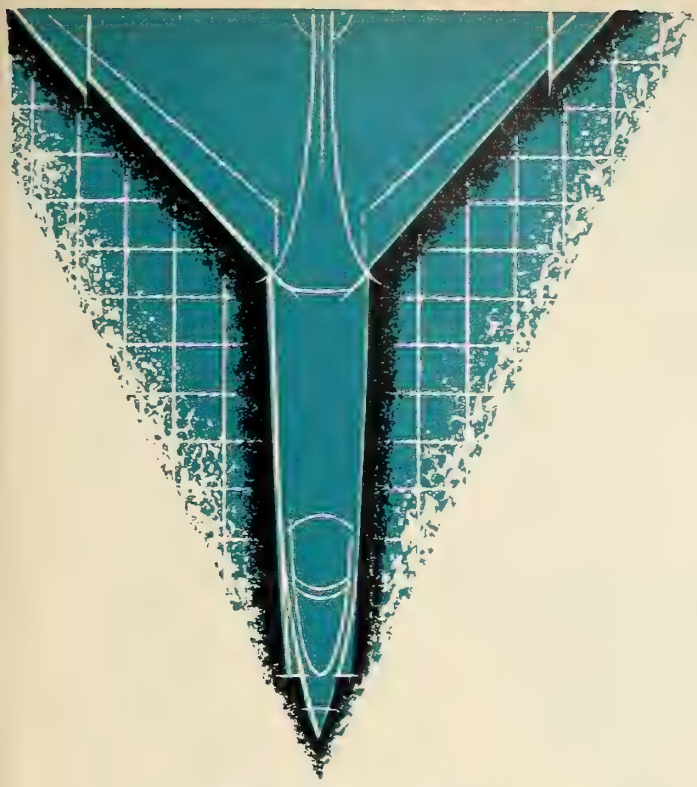
Russian Space Satellite Propaganda

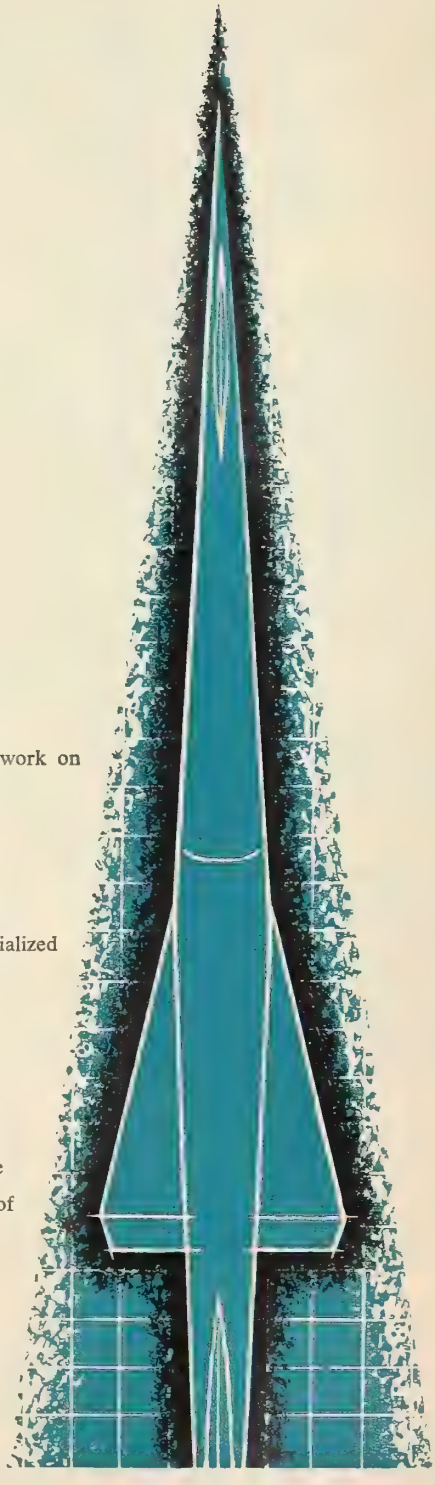
The January issue of USSR, the Soviet propaganda magazine published in the U. S., skips lightly over such warmongering projects as ICBM and IRBM and paints a rosey picture of tomorrow—a day that, "relatively speaking is around the corner," USSR says, when man will send fission-powered suns into space to light and warm the Arctic icelands into verdent lands of Eden.

Also, as you read this issue of USSR, you're told of intercontinental ballistics passenger liners serving contented passengers vodka and sturgeon roe, while the hot little hazard to space navigation mentioned above speeds brightly across the rocket's bow.

In one article entitled "Excursion Into the Future", Soviet writer Vasili Zakharchenko suggests an artificial satellite "shot up into cosmic space" that will orbit the earth at an altitude of hundreds of thousands of miles. This "helio-satellite" would be powered by controlled fusion and would glow brightly over the cold polar regions. But by preset controls—in the middle of this 100,000,000° hot spot presumably—it would switch to low power and glimmer only dimly, conserving its fissile fuel, when passing over the earth's more temporate zones.

Writer Zakharchenko, doubtlessly only because he didn't wish to bore his non-technical readers, decided not to even suggest how all this might be done. In the same article, there's a glowing account of the relative simplicity and immense benefits of daming the Bearing Strait and pumping warm pacific currents into the Arctic with the aid of a two million killowatt system of atomic power stations.





Soviet Rocket Launcher Revealed

When the British entered Port Said in Egypt, they found a large cache of Soviet arms. Among the captured items was a Russian rocket launcher. The anti-tank weapon is surprisingly similar to our old 2.36-inch rocket launcher, the "Bazooka." Indeed, dimensions appear to be highly copied. However, there are some differences, since the Russians have had over ten years to make changes. These modifications are:

1). New fuze.
2). Driving bands on the rocket body (the rocket may be spin stabilized).
3). Blast holes visible on the rocket tube motor (prehaps to vent combustion gases forward to increase muzzle velocity and/or to imprint spin).
4). Large rear cannister (for use either as a barrel wing or for loading into launcher tube only).
5). Shorter launching tube (by about ½-ft) than our old "Bazooka."

Each round is about 17-18 inches long and has a diameter of 60-70 mm. Weight is 3-4 lb. The launcher is about 4 feet long. Construction is extremely rugged and of good quality. Performance characteristics are unknown.

DESIGN ENGINEERS

Perhaps you are wondering which way to turn for real pioneering work on a complete aerial weapon. The missile field offers you a role in advancing our newest family of weapons. Fighter aircraft offer an increasing challenge in human engineering as we equip pilots for new speed and space conquests. In both fields, unique attractions for imaginative designers abound. Yet seldom in today's ultraspecialized organizations is the designer privileged to contribute to *both* fighter and missile development. An exception is Chance Vought's integrated missile and fighter design organization. Here's a rare opportunity to experience the varied career advantages of piloted and pilotless weapons, and to apply applicable design lessons of one field to the other. There may be a place for you with the developers of the Regulus missile and Crusader fighter. Send a resume of your background to:

Rocket Trends

By Erik Bergaust

Russia's missile arsenal is vast. In fact, as our editors put together the bits and pieces of information for this issue, and as we finally arrived at some kind of analysis, we had before us a pretty complete picture of a nation that truly has become a mass producer of rockets. We learned that Red missilry and rocketry for the first five post-war years were based solely on German hardware and know-how. But since 1950 the Russian military machine has produced weapons of communist designs. We also learned that the Soviets do not tend to build up complex arsenals consisting of a variety of missiles, rather they concentrate on a few standard weapons—probably because they can achieve weapon system reliability and simplicity in this manner.

Furthermore, we have learned that two of the Soviet's operational missiles—counterparts to our *Honest John* and *Redstone*—namely the T-7A and the *Comet* are being produced by the thousands. As a matter of fact, the Russians gladly donated a T-7A to the Polish astronautical exhibition that is currently touring satellite countries *(see page 74)*. The *Comet*—which intrigues us immensely—is Russia's 650-mile rocket (thus it exceeds the *Redstone* in range); this is the Korolov rocket, or M-102, which has been confirmed to us by several reliable sources. These sources also say the Russians have produced at least 20,000 of the M-103, an IRBM-type vehicle which is said to have a range of 1,800 miles. Now, a stockpile of 20,000 IRBMs is indeed frightening—when you know that we haven't yet started production on the *Thor* or the *Jupiter*.

Speaking of our own IRBMs, it is interesting to note that while the powerplant for the *Jupiter* has been referred to as a 150,000 pound thrust engine, the Russian IRBM, in spite of the fact that its range is said to be 1,800 miles, uses a 250,000 pound first-stage rocket and a 77,000 pound second-stage unit. This leads us to believe Russian hardware is bulkier and heavier with more dead-weight, and, designwise, we therefore are ahead of them. Our missiles might be more compact, and if you will, more "streamlined"—nevertheless, such comparisons do not serve much purpose. What counts is the fact the Russians are on a par with us, and capable of employing long-range missiles today.

We often ask oursleves how the Russians possibly could have obtained the know-how and skills that are required to build up the missile and rocket potency which they now possess. Certainly, these results do not stem from German or other foreign aid, although such assistance might have been helpful in the early years. It seems, however, that Senator Symington has a good point when he stresses that the Reds are capable of gaining rapidly in the technological race between our two countries, because their war industry doesn't suffer from the bureaucracies that are so unavoidable in a democracy. Another point: the communists know only too well how dangerously they are surrounded by our "threatening, imperialist" bases, and the answer—in the communist mind—might be a great amount of launching sites and an equally vast amount of missiles.

Finally, let us mention that it took quite a bit of doing to get this issue out. And we are grateful to all our editors, correspondents and contributors and to our special sources overseas. This issue, with some 40 pages of editorial material on Russian missiles, rockets and astronautics, is the result of compiling and sorting and checking hundreds of reports, articles and books. Particularly, we wish to emphasize the tables on Russian missiles on pages 36 and 37—to the best of our knowledge, this tabulated presentation is the first ever attempted in this country. These tables, mapping the Red missile arsenal, give a good picture of the trends behind the Soviet's missile goal. Indeed, we hope we shall never experience the activation of this arsenal.

ABMA Has First Birthday Party

Huntsville, Ala.—The Army Ballistic Missile Agency observed its first anniversary on Feb. 1st with a celebration as close to an "open house" as that closed post will permit.

Several hundred civic leaders of Huntsville and the surrounding areas were special guests and were escorted on a limited tour of the facility, shown recently completed movies that are being used for recruiting purposes and were treated to a brief demonstration of a missile being fired from a test stand.

In its first year, the ABMA has expanded from a handful of military and civilian employes to an organization of some 4,300 persons and, judging from stepped-up employment in recent weeks, may well double its personnel during the coming year.

The dollar value of the physical facilities has jumped by some $10 million from $46 million a year ago.

Nearly $26 million in construction is under way at present, and an additional $20 million is being planned.

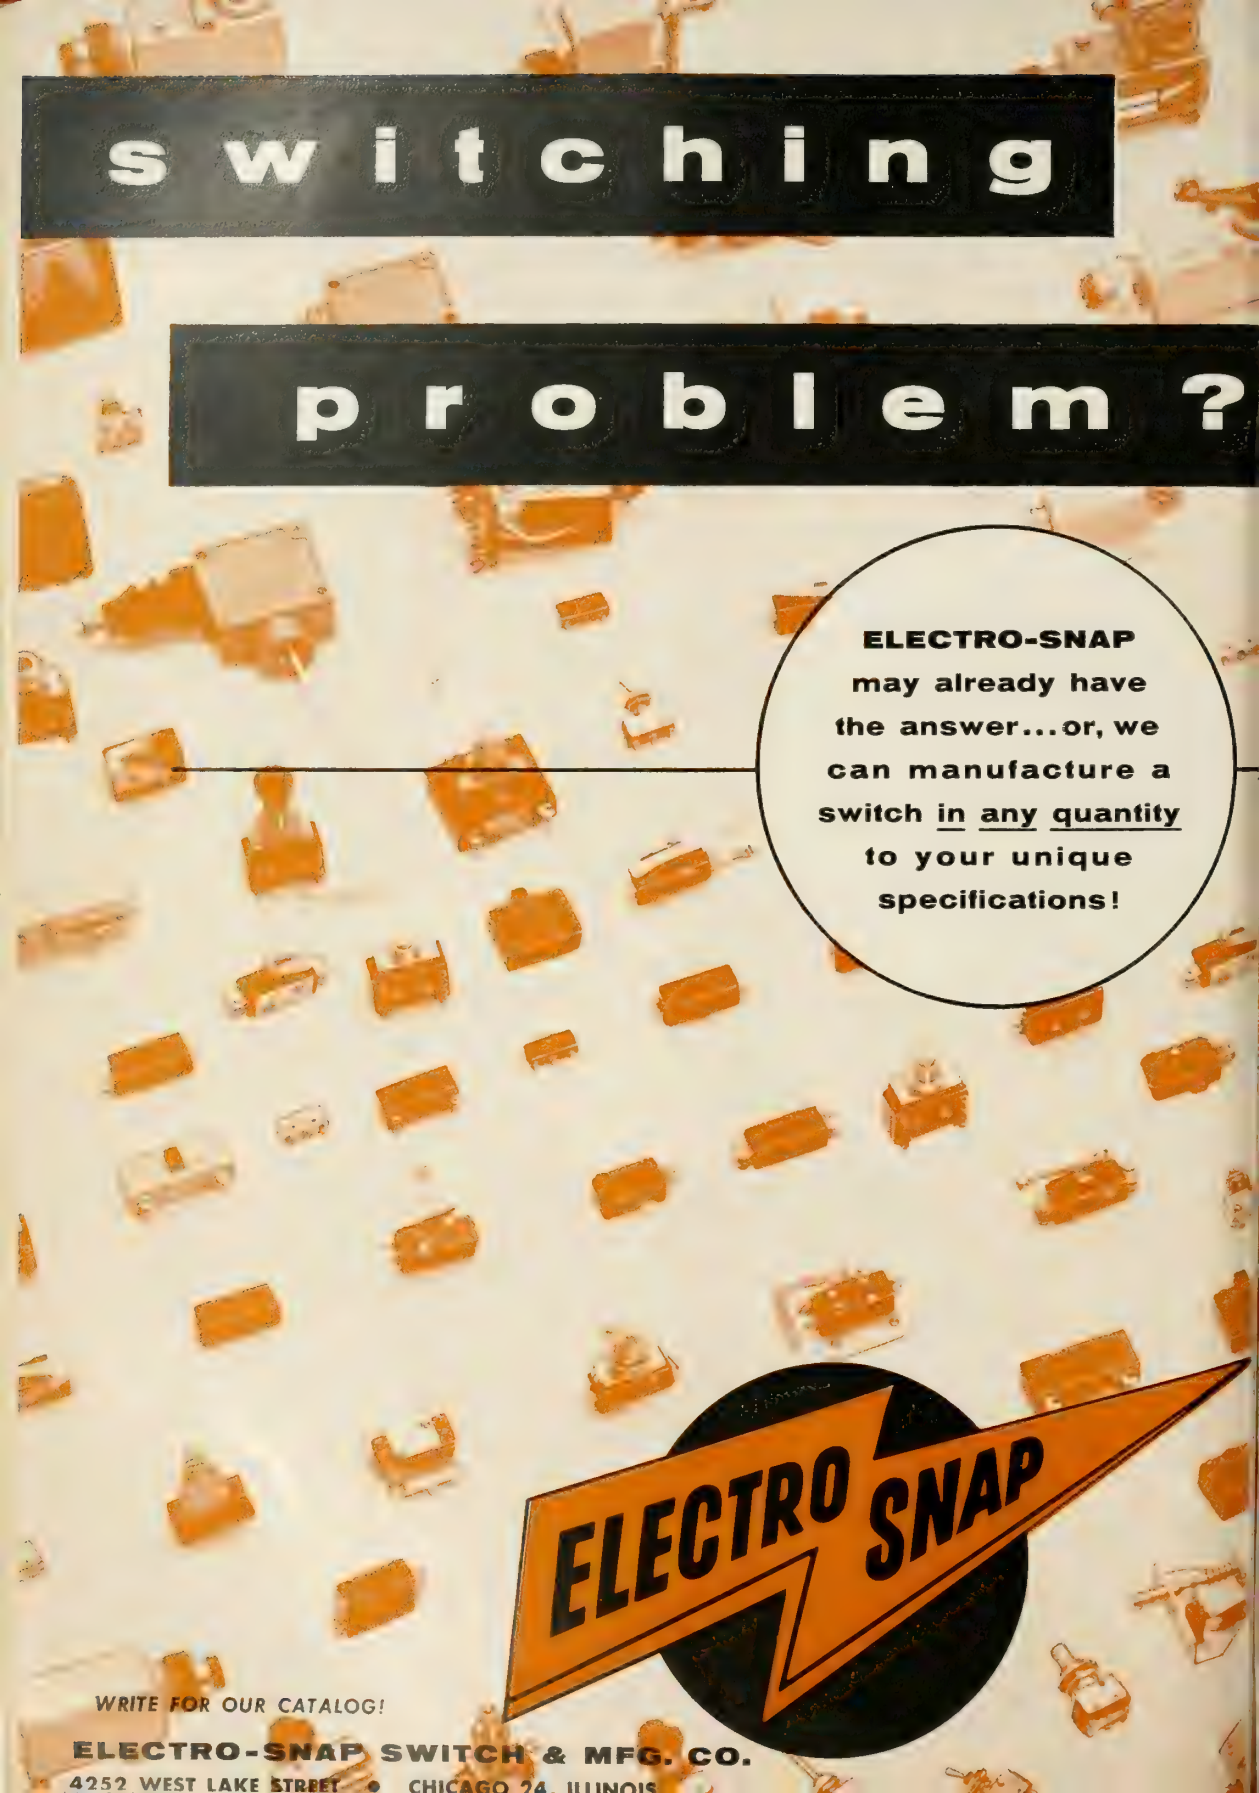
The Army's first *Redstone* missile battalion, the 217th Field Artillery, has been formed and is now being trained at ABMA.

NATO Delegations Visit at Redstone

Huntsville, Ala.—Six officials representing the Federal Republic of Germany (West Germany) received an orientation course in missile and rocket development and use at Redstone Arsenal and Army Ballistic Missile Agency recently.

The German delegation included four retired military officers: Lieut. Gen. Wolfgang Vorwald and Cols. Joachim Luetzow, Maximilian Bohland and Kurt Braennig; and Dr. Walter Hofmeir and Mr. Otto Baier. Their visit was under auspices of the U.S. Departments of State and Defense.

The concern of the NATO defense forces with missiles and rockets has been mounting steadily, observers note, since the announcement in 1954 that the jet fighter-bombers supplied to them under the Mutual Defense Assistance Program were capable of using missiles and rockets with nuclear warheads, and the subsequent stationing abroad of U.S. Army and Air Force units equipped to fire such weapons. The first school for NATO forces dealing in atomic weapons is said to have been held at Oberammergau in the Bavarian Alps some time ago.



CENTRICORES are processed from thinner gauge materials including Hymu, Squaremu "79", Squaremu "49", Microsil and "49" Alloy for magnetic amplifier and special transformer applications. New sizes are being constantly added to standard sizes available from stock for prompt delivery. *Write for Bulletin C-1* covering magnetic properties. Also indicate where Magnetic Amplifier test procedure data is desired.

m/r exclusive:

Russia's Guided Missile Program

By the editors of m/r

THE SOVIET UNION'S arsenal is today bristling with missiles and many of them are in just as an advanced stage of development as their U.S. counterparts. In all phases of missile activity the Russians are making tremendous headway and at the present time have a formidable array of guided weapons in operational status. Of particular significance is the crash program on ICBMs. Present indications are that an ICBM will be available for operational use within two to three years. This is the 5,000 mile range T-3.

While Russia's ICBM is being rushed through the development stage, test firings of an IRBM are in full swing. Several test firings of the T-2, a two stage IRBM with a range of 1,800 miles, take place each week. In operational status is the T-1, an MRBM with a range of 400 miles.

There is a developmental connection between the T-1, the T-2 and the T-3. The T-1 is actually an improved German V-2 (the Russians built about 1,000 V-2s to acquire production know how and for training, and aerodynamic and upper atmosphere research). The T-1 had a powerplant with improved performance, thanks to the use of hotter-burning kerosene in place of alcohol, increasing the chamber pressure, and some weight shaving. The result was that the thrust went up to 77,000 lbs. and the range to 400 miles.

The next stage in Russia's ballistic missile program was to take over the drawing board A4/A9 project and to develop an engine with a thrust of some 254,000 lbs. for a two-stage IRBM, the T-2. From the T-2 came the T-3 ICBM which is being given top priority by the Russians.

Because of the Soviet Unon's insistance that the IRBM and ICBM programs be rushed through, the status of the winged A4 (T-4) is not known. Also unclear is the position of the T-4A, a development of the Saenger antipodal glide bomber.

In the low-range ballistic missile category, the T-7A is still one of the main weapons of the Red Army. This is a solid propellant rocket with nuclear capabilities for tactical use. The T-7A may in fact be approaching obsolescense since versions of it have been made available to the Polish and East German armies for some long time.

In the field of anti-aircraft missiles the Russians are in good shape. Long aware of the threat implied by the existence of large USAF B-29 and B-36 bomber forces, they placed into operation several years ago the M-1 AA missile (Table 2). A higher performance missile in this category is the T-7 which was designed to defend Russian targets against attack from B-47 and B-52 bombers. The T-7 has been in operation for some time and U.S. authorities have confirmed AA missile sites around most large centers. Furthermore, a well-developed radar tracking and warning network stretches all along the Soviet perimeter, from Eastern Europe along the Siberian coasts to the Pacific Ocean.

For low altitude targets the Russians use the T-8 barrage flak rocket system. Two other flak rockets are the T-6 and the GVAI. Both of these probably use double-base solid propellants.

Vast Naval Missile Arsenal

The Soviet Navy is well supplied with missiles. The growing Russian submarine fleet (about 100 under construction and 400-800 in operation) could isolate Europe and allow most of the U.S. and Canada to be hit with existing ballistic rockets. In addition vigorous development of cruise weapons has taken place (Table 3). Another Naval weapon under construction in the Soviet Union is the *Comet* underwater-launched ballistic missile (Table 4) which is likely to have a range of 500-700 miles.

The Soviet Navy is being equipped now with missile ships as well as fast and modern destroyers. Several anti-aircraft missile ships have been sighted in the Baltic and the Pacific together with short and medium range missile-armed attack ships. Naval intelligence now admits that the Soviet fleet is second only to the U.S. in numbers and is growing fast. Russian shipyards are so tied up with naval construction, that all merchant vessels are being built in foreign countries.

In the air-to-air missile field, the standard item is the 3.2-in. rocket which like the U.S. 2.75-in. folding fin aircraft rocket (*Mighty Mouse*) is patented after the German WWII R4M. The M-100 guided aircraft rocket has been radically streamlined and cut in weight. It appears that the new M-100A is about 6-10 feet long with a maximum diameter of 8-10 inches. Equipped with four swept wings aft, the unit is small enough (100-200 lbs.) so that several can be carried by a jet interceptor in addition to a compliment of 3.2-in. aircraft rockets. It is no secret that the USAF is worried enough about these Russian aircraft rockets to give top priority to the development of bomber defense missile systems.

It is not believed that the Russians are relying on manned rocket aircraft to any large extent for the defense of key targets. It is known however, that a VTOL rocket interceptor, the I-2 has been developed. Paper specifications for this aircraft called for an endurance of 7-10 minutes and top

speed well over Mach 1. Armaments specified were 37-mm cannon or 3.2-inch aircraft rockets. The I-2 is a distant relative of Germany's Messerschmitt 163 rocket plane. Impressed with the high performance of the rocket-powered interceptor the Russians tried rocket power to boost the standard power plant of the Yak-21 and the LA-17. This lead in time to the I-1 research rocket aircraft from which the I-2 seems to be a derivative

No Doubt About ICBM

Without stating their sources, several American leaders have revealed details of Russian missiles from time to time. Senator Stuart Symington, on July 21, 1954, told of the Russian attempt to build an intercontinental ballistic missile with a hydrogen warhead of 4,000 to 5,000 mile range. And on May 18, 1955, Rep. Overton Brooks, member of the House Armed Services Committee said "dozens of points in Europe and Asia . . . in a pattern allowing an arc of fire to cover, for instance, the Baltic Sea, are being built for guided missile launching sites."

Senator Symington said: "I don't believe the Soviets are ahead of us in ballistic missiles. I state that they *are* ahead of us in ballistic missiles."

It seems the Russians are at least on a par with us in ICBM rocket engine development. As a matter of fact, it sometimes looks as if the Russians tend to overpower their missiles. Their IRBM, for instance, is powered by a 250,000 pound first-stage rocket plus a 77,000 pound thrust second unit.

On the other hand, their ballistic missiles might lack the accuracy that we claim for our guided weapons; many experts that we have talked with lately are inclined to think the Russians are somewhat behind in guidance and control. Then, again, US engineers who have attended international electronics conferences and seen Russian electronics gear, praise the communists for their advanced all-quality equipment.

Since the Russians took over Germany's Peenemünde with all its gear and hardware, they could resume production of a fabulous weapons system; submersible ballistic missile launchers. With her 600 submarines and this new concept in IRBM warfare Russia has a striking power that will be difficult to match.

Dr. Walter R. Dornberger, former Peenemünde Commandant, brought this concept to the attention of Defense Department officials several years ago, reporting that submersible missile launching platforms to be towed by submarines had been developed by the Germans at Peenemünde. Despite the fact technical reports on these developments were brought to this country a long time ago, no United States project of similar character is known to have been attempted.

The Russians, in fact, are capable of towing huge ballistic rockets 50 feet high in submersible containers to areas hundreds of miles off our coasts. The containers are about 115 feet long with a volume of 14,000 cubic feet. From different locations their missiles could be launched simultaneously against targets on the mainlands. With a range of 1,500 miles—or less—the Red missiles literally could be used against any significant target on the American continent.

Furthermore, this potentiality exists today; the Russians do not necessarily have to wait for completion of their ICBMs to obtain the equivalent firepower. Dr. Dornberger has said he believes the Russians "emphasis on underwater vessels indicates a plan to use submarines offensively, in American waters, quite possibly as tow vessels for missile launchers."

Three slightly different missile-launchers were built by the Germans, and they were all taken over by the Russians, who have had 12 years to complete this weapons system—which, incidently, was almost perfected by the Peenemünde engineers at the end of the war. The launchers, now believed to be mass-produced by the Russians, were first suggested in early 1944 by Dr. Dickmann of the famous Vulkan Werft (Vulcan Works) in Stettin.

Developed in the greatest of se-

Comparison of some typical USSR and USA ballistic missiles

crecy under the code names *Project Swim Vest* and *Project Test Stand 12*, Peenemünde's top scientists, led by Dr. Wernher von Braun, were working on the missile launchers.

Designed for V-2 missiles, the submersible launching platforms were fitted with a control station, tanks for liquid oxygen and alcohol, water ballast tanks and a gyro system to counteract yaw and roll under towing as well as when the launcher was in upright position for firing the missile from its inside. The net weight of the launcher was 70 tons; the missile, its propellants and accessories represented 35 tons. Ballast amounted to 300 tons.

Three launching containers could be towed in submersed position by one submarine at 15 mph. One launcher could be towed at 20 mph. The range was limited only by the fuel supply of the submarine. With specially designed vacuum-insulated tanks the loss of liquid oxygen during transportation was kept as low as 1%.

A series of problems and difficulties were experienced by the Peenemünde engineers during the first tests. In particular, the greatest problem was to keep the launcher stable under transport as well as under firing of the missile. Large rudders activated by the gyro-servo system were used to obtain stability during horizontal operations. Certain hazards were connected with the excessive amount of hot steam that was formed during firing.

The rocket exhaust escaped through funnels, but the terrific heat from the gases caused the water in some of the ballast tanks to boil, forming steam which had to be vented to the asmosphere. Vent systems propellant fumes also were incorporated to minimize the explosion hazards.

It took the Germans—on a wartime crash program basis—only two years to develop the missile launchers, and it seems obvious that the Russians, who took over the equipment, have been able to solve whatever problems the Germans did not have time to solve.

Design criteria for the submarine launchers include an intricate pumping system for the water ballast, as well as a complex electrical system for operation of instrumentation, gyros, pumps,

lighting inside the launcher and for testing prior to firing. Three technicians can handle the launching of a liquid-propellant ballistic missile.

A conservative estimate indicates it will take less than half an hour to launch a missile after the tow submarine has reached its destination. By remote control from the sub some of the water in the upper ballast tanks will be pumped out, the launcher slowly tilts into vertical position, and only the nose is above the surface.

The technicians, entering from a rubber boat, will open the clam-shaped doors and plug in the electrical connection. A ladder leads down to working platforms and the control room. Gas fumes will be vented to the atmosphere, electrical motors started, and the missile activated and pressurized for fueling and launching.

The technicians will leave the launcher after proper testing of instrumentation and setting of the warhead fuse and guidance. The fire control is handled from inside the submarine. The launcher may be abandoned, or, if circumstances permit, it may be towed back to base or a mother ship and be made ready for use again.

The range of a V-2 missile, when launched from a submersible launcher, was considerably reduced because of the back pressure caused by reversing the rocket exhaust 180° through funnels.

However, with improved rocket engines and lighter components, it is permissible to assume that Russia's T-1 or the *Comet* will be capable of covering hundreds of miles, when fired from a submarine launcher. Significance of this launching method is that the missile may be transported undetected.

this launching method is that the missile may be transported undetected.

Inter-service Rivalry?

It appears Chief Marshal of Aviation, N. F. Zhigarev, is Russia's missile czar. Furthermore, it seems obvious the communists have decided to give the Red Air Force the responsibility for all ICBM development. Strangely enough, however, long-range missile launching sites are manned by personnel from both the Army and the Air Force. As a matter of fact, there is more Army personnel involved than Air Force people. One of the reasons behind this concept stems from the fact the Red Army is still "more important" to Russian defense than the Air Force or the Navy. And there could possibly be a question of whether the Air Force —which normally requires skillful personnel—has enough trained field operators for the launching sites. In other words, this situation might change.

While there's no doubt inter-service rivalry is dominant in Russia—as it was in Germany, and as it is this country—all three services have been included IRBMs in their arsenals. The bombardment threat Bulganin referred to last fall—when he stressed that Russia had missiles that could bomb England from East Europe installations—is understood to have been based on Red Army missiles, rather than Navy or Air Force weapons. However, this should not be construed to mean that the Red Air Force and Navy are not capable of attacking Great Britain from far-away launching sites.

All production of missiles in Russia, of course, is under direct Government supervision and sponsorship. There is no private enterprise involved whatever, and even the design competitions among universities and scientific institutions are 'all-government' handled. Yet, there is keen competition between factories and between design outfits. High awards are offered for efficiency, high-production schedules and for all-quality end results. The individual "hero awards" that we hear of so often apply to the missile business as well. Numerous "scientific workers"—which is the Red term for scientists—have struck it rich. Thousands of rubles have been given away each year to individuals working in basic sciences—in particular in the fields of mathematics, physics and chemistry.

The Russians put an enormous emphasis on chemistry, partly because the country has been way behind the rest of the civilized world in this field until recently. Very few synthetic materials had been employed in Russia previously, but thanks to a modern chemical industry, and an advanced one, the communists now are begin-

ning to benefit from and apply more and more plastics and resin materials. In turn, the growing chemical industries are yielding more and more to the armed services in terms of useful by-products and know-how for the rocket propulsion industries.

Atomic rockets also are being worked on in the Soviet. There is no report however, on whether they have as yet attempted to construct any nuclear rocket hardware. But since the Russians know we are doing so, one can rest assured that it won't take them long to follow in our footsteps. A report on Red nuclear rocket trends was given in m/r October 1956, and a further analysis will be given in a special issue this spring. Reports on Russian "scientific workers" and Red capabilities in the basic sciences appear in m/r's *special report* appearing on page 61 of this issue.

Dr. Sedov has confirmed that Russian atomic rocket research is progressing at various nuclear research centers throughout the Soviet Union.

A short time ago Russian research engineer G. Nesterenko said that "engines performing on nuclear fuel are of great importance in our contemporary aviation and rocket engineering. Powerful and highly efficient atomic engines will enable us to build rockets that will overcome the gravitational pull of the earth."

Rocket engines with atomic reactors mounted directly in the combustion chambers have been discussed openly in Russia. Active U235 and U238 reactor mass and a graphite neutron inhibitor have been suggested.

This early Russian missile was powered by a liquid rocket engine. Its launching weight was 3,300 lbs. and its top speed was Mach 1.3. It was 15 ft. long and 24 in. in diameter.

Liquid hydrogen will flow through the porous mass, cool the reactor and at the same time acquire tremendous energy. Nesterenko has calculated the exhaust velocity to be in the neighborhood of 22,000 feet per second.

Extensive Research

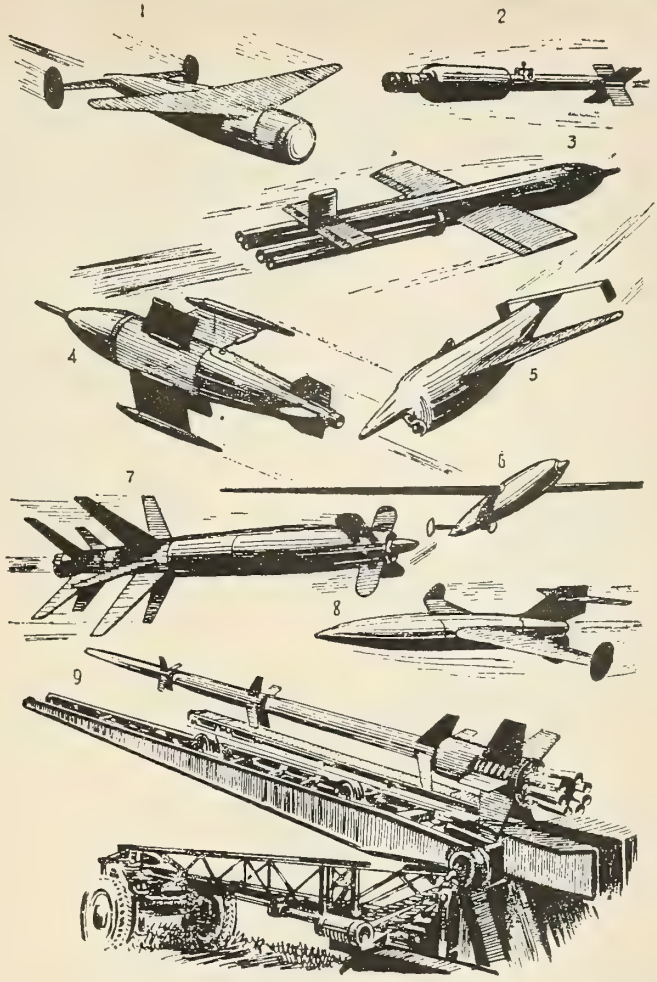
In the research field the Russians have done considerable work. Animals have been fired to altitudes of 250 miles. A large amount of supersonic and hypersonic aerodynamic and other research work is being carried on both within the Soviet Union and in Russian satellite countries. Poland recently displayed several and multiple stage rockets with Mach 4 capabilities at its Technical Museum. However, the pride and joy of rocket research is the Red satellite effort (See "Soviet Astronautics" in this issue). Even before the Russians announced their satellite intentions, the U.S. was concerned about the implications of the satellite detection centers established in the Soviet Union. Latest word is that the Soviet Union desires to establish a satellite of about one ton in weight.

The whole Russian missile and satellite program is being conducted with the full support of Red Air Force Chief Marshal Zhigarev who believes implicitly in the value of the ICBM. Special Weapons Chief, General A. S. Yakolov is believed to be the missile hardware man in the Soviet Union. Russian rocket efforts appear to be centered in the ZIAM's institute in Moscow. Another important missile development center, particularly for ballistic weapons, is at Khimki near Moscow. Under recent dispersal programs subsidiary development centers have been set up in various points throughout the Soviet Union including some in the Ural Mountain area. Kuibyshev is probably the main center for missile powerplants. Colonel Andrei Kostikov, well known inventor of the Katyusha Salvo guns, has his headquarters in Kuibyshev. The Frunze engine plant in Kuibyshev is producing rocket motors in quantity.

Production of ballistic missiles is scattered over the entire Soviet Union. It is estimated that Russia has the capacity to build some 2,000 monthly. One of the original ballistic missile plants was factory no. 456 in Moscow. Another important ballistic missile plant is in Tomsk. A subsidiary plant of the ZIS automobile concern also is

Chief Marshal of Aviation N. F. Zhigarev, head of the Red Air Force, is an implicit believer in the missile and was largely responsible for convincing the Soviet government of the need to put the ICBM on a "Crash" basis. He is also reported to be encouraging top priority development of space weapons. These top Soviet missile planners were grouped together during the aviation day show at Moscow's Tushino airfield last June. Marshal Zhigarev, Red Air Force chief is speaking. At the left is Marshal Zhukov, Soviet defense minister while Marshal Sokolovski is at the right.

working in the ballistic missile field. One of the more recent developments in the Russian missile production program has been the establishment of plants in the Far East of the country. There was virtually no missile activity east of Lake Baikal until the beginning of this decade. Now, however, there are modern plants at various points in eastern Russia including a big assembly plant at Komsomolsk on the Amur River. The map that accompanies this article indicates the extent of Soviet missile plants and development centers. This map also shows the location of the principle Russian missile bases. The existence of most of the launching bases shown on the map has been confirmed. It also is thought anti-aircraft missile batteries ring all of the most important Russian centers. The ballistic weapon launching bases are located on the Russian perimeter including many points in the far north.



There are also strong indications that Russian missiles have been supplied to the satellite nations. None of these nations have any missile programs of their own although several of them are known to be large scale contractors to the Russian missile industry. East Germany for example, is still an important source of material for missile guide systems although the Russians are rapidly becoming independent in the electronics field.

The Russian dependence on Germany for missile design is long past history. From 1945 to 1950 the Russian effort was almost 100% based on the wartime work in Germany and was carried on by German engineers who were enlisted for duty in missile development in the Soviet Union. From 1950 to 1955 there was a transition with most of the Germans going back to their home land and independent Russian designs taking the place of the German missiles, powerplants and guidance systems. Since 1955 the Russians have been completely independent of German brain power, although most of the current missiles reflect the German thinking that conceived them in their early stages of development. There is some evidence that the Russians are still using Peenemünde missile base in East Germany for certain research projects.

Nonetheless, all evidence indicates that Russia is now on its own in the missile field and is doing well. Missiles enthusiasm abounds among the entire Russian executive class. The apparent attitude of Russia's leaders is to have large quantities of reliable missiles available as quickly as possible. As is the case with most Soviet weapons, the emphasis is on simplicity and reliability.

Although there has been much talk of automation in the Soviet Union —Russia has its own Ministry of Automation in industry—little is known of the current status of many projects. However, it has been reported that some 200 automatic production lines are to be introduced in the course of the current 5 year plan and undoubtedly many of these will be applied to aircraft and missile plants.

Although production methods and techniques are very old fashioned by western standards there is no doubt that the Russians are turning out missiles in quantity. The stock pile of anti-aircraft missiles and IRBMs should certainly be regarded with respect while the imminence of the Russian ICBM is a threat of the first magnitude. The ability of the U.S. to surpass the Russian effort is a key factor in determining the future cost of mankind. ★

U.S. Military Leaders Warn of Red Danger

Reds Put Emphasis on Rocket Power, Long-Range Missiles, Subs

It was a coincidence that while the editors of m/r were winding up their research for this issue, three U.S. military leaders, Army Secretary Wilber M. Brucker, Assistant Secretary of the Navy for Air Garrison Norton, and Western Development Division Chief General Bernard A. Schriever presented significant speeches on the subject of the increasing danger of the Red war machine.

Not Just Plain Talk

Such speeches frequently have been given by military and political leaders in this country during the last few years. On rare occasions only have any such leaders stood up and told the American public what we have achieved in terms of actual hardware and in terms of the technical advancements that you can put your finger on. It was gratifying, therefore, to hear General Ben Schriever present his speech recently before the Institute of Aeronautical Sciences on guided missile research and development in the United States Air Force, for the WDD Chief plainly stated we now have a broad foundation for United States leadership in ballistic missiles. This is based on the fact, according to the General, that all major milestones for the *Thor, Atlas* and *Titan* development program have to date been passed on schedule.

One factor that has often been overlooked in the missle race was stated by General Schriever:

"There has been much speculation as to whether we or the Soviets will have bigger and better ballistic missiles. This is somewhat like weighing the chances of the participants in an automobile race solely on the basis of their cars instead of also considering the training and experience of the drivers, the reliability of their equipment, the support which they receive in the pits, and similar factors.

"A broad foundation has been created for U.S. leadership in ballistic missiles—a foundation which may also serve to assure U.S. leadership in future space technology.

Air Force WDD Chief
General Bernard Schriever

The Ultimate Respect

"However, the data which would serve best to prove these points convincingly cannot be told for security reasons because those are the very data on which our leadership rests. Suffice it to say that the broad breath and great depth of the ballistic missile program assure ultimate achievement of our goal, without depending on one success or facing defeat on account of one failure.

"There is one final question—what will we have achieved when we reach our goal—when ICBM's and IRBM's have become reliable, operational weapon systems produced in quantity? Paradoxically, the best we can hope for is that we will never have to use these weapons; that our ballistic missile capability will be so highly respected by all potential aggressors as to indefinitely deter them from attacking us.

"This should not imply that the ICBM or IRBM are "ultimate weapons" as they are frequently called. Nor will the ballistic missile replace the manned intercontinental bomber. But it will undoubtedly become one of the most potent and convincing arms in our arsenal of strategic weapon systems."

Army's Brucker: Soviet Leaders Fool Themselves

"America can hope to lead the world to a just and honorable peace only if we all remain staunchly true in every sphere of activity to the great moral concepts upon which this Nation was founded—the lofty ideals which have been the driving force behind its advancement through the years to a

Secretary of the Army,
The Honorable Wilber M. Brucker

position of preeminent power and prestige. Uncompromising Americanism is the only solid foundation upon which we can stand to do battle with the communist monster.

"We have had ample warning of of the danger we now face. For a short time not many months ago, numerous people throughout the world, including some in our own land,—imagined they saw reason to believe that the leaders of the communist conspiracy had experienced a change of heart—that they had abandoned armed aggression as a means to attain their ends, and honestly sought peaceful resolution of the world's differences. Dead Stalin was denounced by his confederates. Sweet words and disarming smiles briefly replaced his intransigent hostility to the Free World.

"How utterly this phantasy of Soviet 'reformation' has been shattered. The merciless butchery of liberty in Hungary, the open efforts of the Soviet Union to obtain a military foothold in the vital Middle East, which Russia has coveted for centuries, and the increasingly brazen attempts of the leaders of the Kremlin to stir up dissention wherever possible, and exploit unrest in order to extend their power have served notice on all free nations that freedom everywhere is in greater jeopardy today than it has been for many years.

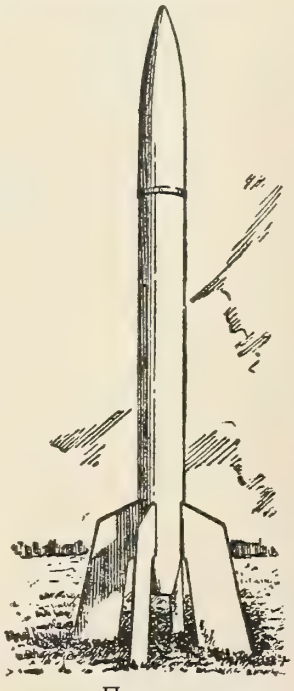
"In addition to the testimony of evil deeds, we have Khrushchev's strident boast to the West: 'History is on our side. We will bury you!' Only a week ago,—in virtually reconsecrating Stalin as the patron saint of militant communist imperialism—Khrushchev reiterated his warning that the Soviet Union will contribute in every way it can to the death of the Free World. How could any threat be more plain?"

"Soviet leaders are fooling no one but themselves when they call upon history to justify their trust in the ultimate triumph of the ideologically bankrupt communist tyranny. If Khrushchev and his fellow conspirators read the record straight, they must realize that no despot can take comfort in history. The verdict of time has always vindicated the leaders who have served the cause of freedom and human justice—not the Caesars and Hitlers who have ridden the chariots of oppression over the broken bodies of millions."

(These are direct quotes from a speech given by the Honorable Wilber M. Brucker before the Sertoma Club of Washington January 25.)

Navy's Norton Stresses Red Sub Threat

Assistant Secretary Norton



"As the opposing major powers round out their stockpiles of atomic weapons, I believe it has become increasingly clear to people throughout the world that all-out nuclear war is wholly irrational. We know there can be no winner of such a war. At the so-called Summit Conference the leaders of the Soviet Union gave evidence that they too had come to this conclusion. In so doing they must have discounted, or at least degraded, what hitherto has been considered to be a dangerous military advantage of totalitarian nations over free nations, namely the willingness to make a surprise nuclear attack.

"Now this is not to suggest that we should lower our guard against surprise attack. Well dispersed bomber and missile forces, both land and sea-launched, will continue to be the major deterrent against such attack. What I do suggest is that any Nation seeking to achieve its objectives by military action must develop and employ *alternatives* to all-out nuclear warfare. We know from painful experience that the Soviets have demonstrated great ingenuity and long-range purpose in doing just that, from the construction of by far the largest submarine fleet the world has ever known, to the development of new techniques for armed subversion and infiltration.

"Faced as we are with the Soviet strategy, there is no doubt whatever that we, the leading free nation, must speedily develop alternatives to the nuclear capability upon which we have concentrated so much of our manpower, time, and money. We must place some limitation on it to maintain a sound economy, and at the same time have enough in the budget to provide the flexible, versatile forces that can readily respond to the more likely types of limited aggression and hostilities. If we fail to do this, we shall immobilize ourselves in an era of renewed Soviet aggression.

"Indeed, we must develop alternatives on the political and economic, as well as on the military fronts. Immediately after World War II, I stepped from the Navy into the Department of State, and did a tour of duty as an Assistant Secretary of State. No one is more keenly aware than I, that these other two fronts share equal importance with the military, in the development of our foreign policy. I am not going to discuss political and economic alternatives today. But when it comes to military alternatives, I suggest that you keep your eyes on our new Navy."

(These are direct quotes from a speech given by the Honorable Garrison Norton, Assistant Secretary of the Navy for Air, at an Aviation Writers Association meeting in Washington January 25.)

Первая советская ракета с жидкостно-реактивным двигателем, сконструированная М. К. Тихонравовым.

This Russian rocket was tested in 1933, according to the Russian publication from which the drawing is taken. It was designed and built by engineer M. K. Tikhonravov. According to the Russians it "ascended to a great altitude, changed its direction and flew horizontally for some time before descending to earth." Liquid oxygen was used.

MISSILES & RUBLES

If the Red missile arsenal doesn't match that of the U.S., it's not because of a lack of rubles and what they represent. In terms of economic capacity, the Union of Soviet Socialist Republics has what it takes. The only real doubt is in the level of her applied technology.

Setting aside politics for a minute and a top talent as a global trouble-maker, after one of the most astounding economic growths in history, the U.S.S.R. stands second only to the U.S. in basic industrial capacity.

Add the dictatorship's known ability to concentrate effort where it does the most good, and Russia becomes an adversary of note.

And vital is the fact that Russia could not survive a long, old-fashioned World War II kind of scrap either politically or economically. Her people, like the Satellite populations, are restive. Economically, she can handle the current state of semi-war. But with virtually no consumer goods industry, she's got no give for expansion to all-out effort.

Short-War Concept

Not only does Russia have an interest in missiles as the lastest in weaponry, but the long-range nuclear ballistic missile is the weapon of the short war, or so it's said. And a short war is the only kind of war Russia could hope to win.

Last summer, for the first time in 17 years, the Central Statistical Administration of the Council of Ministers USSR—Red equivalent of the U.S. Census Bureau—published some hard figures on the Soviet economy. The *New York Times*' Dr. Harry Schwartz has compiled an analysis of these figures into a "Statistical Handbook of the USSR ($3, National Industrial Conference Board, 460 Park Ave., N. Y. 22, N.Y.). Careful checking indicates they are at least in the same ball park with reality. They form this basis for this m/r appraisal.

Prior to the 1913 revolution, Russia was a feudal power, with only 17.6% of the population being urban; 82.4%, rural. Today the break is 43.4% to 56.6% respectively. With this shift from the farms to the cities has come massive industrialization — industrialization with gays, true, but not where they hinder Red munitions output. As in the days of the Czars, the mass of the people still come last, the state first.

Since 1913, consumer goods output has gone up 1,000%. So, the average Russian is, in fact, a little better off. But the output of goods for production is up 5,200%.

Spurred on by World War II and open Cold War with the West, the greatest expansion of the Soviet economy has occurred since 1940. The population has risen only 5%, 191.7 million to 200.2 million as of April, 1956. But by 1955 basic industrial output had jumped in most cases over 200% in 15 years. The sixth and current five-year plan calls for 1960 totals to be 50%-to-150% up again. Table on this page gives some actual figures.

Notably, nothing on defense related industries, such as non-ferrous metals, aircraft, electronics, etc., has been released. However, it's known that munitions come only after basic industry in the concentration of Red effort.

With basic production now in hand, Russia is turning her attention to standards of technological research and development. In the missile business, this is significant. For the pounds of actual hardware in a missile are few. It's how they're arranged that counts.

In this connection, the number of "specialists with higher education" has jumped from 908,000 in 1941 to 2,340,000 in 1956. Of these, engineers are up from 290,000 to 586,000.

While shortcomings of Red technology are still apparent in many fields, they are least obvious in heavy industry and munitions. The heaviest presses and largest milling machines are still claimed by Russia. And while her claim to operational IRBM's has yet to be proved, her abilities in the demanding arts of jet aircraft and atomic power are evident.

Additional figures quoted support this appraisal. For example, industrial production workers have increased from 8-million in 1932 to 17.4 mililon in 1955. The availability (not output) of metal-cutting machine tools has increased from 710,000 at the end of 1940 to 1,760,000 a year ago; press and forging equipment, from 119,000 to 365,000. And while are not truly quantitative, since they don't say what kinds of tools, U.S. technicians who have seen Soviet equipment respect it.

And in the strange ways of the Communist statistician, this for what it's worth: In 1950, 555,000 people offered 1,241,000 of which 655,000 were adopted in production. In 1955 the figures were 1,138,000, 2,080,000 and 1,160,000 respectively.

Reds Have Capability

Though none of this adds up specifically to "missiles in production," even in exaggeration the figures leave no doubts as to Russia's basic economic capacity to make missiles. Aided by a lot of stealing, borrowing and extrapolating from the West, plus a growing volume of new development on their own, Red technical ability is moving up on the West in more and more fields. In a few words, if the Soviet theoretician knows how to make an ICBM, Soviet industry can carry his paperwork to the operational stage. There are persistant reports that this is being done.

Soviet Basic Industrial Production
(in units unless otherwise stated)

	1913	1940	1955	1960
Pig Iron (1000 tons)	4,200	14,900	33,300	53,000
Steel (1000 tons)	4,200	18,300	45,300	68,300
Rolled Metal (1000 tons) ..	3,500	13,100	35,300	52,700
Coal (1000 tons)	29,100	165,900	391,000	593,000
Petroleum (1000 tons)	9,200	31,100	70,800	135,000
Elec. Power (million kwh) .	1,900	48,300	170,100	320,000
Metal-cutting				
Machine Tolls	1,500	58,400	117,800	200,000
Large, heavy & unique ...	....	212	3,541	not said
Press & Forging Machines ..	....	4,700	15,900	25,800
Motor vehicles*	....	145,400	445,300	650,000

* This includes both trucks and passenger cars and was included as typical of the low proportion of effort going into consumer durables.

Soviet Astronautics

Red IGY Satellite to be Launched by Help of ICBM Hardware

By Alfred J. Zaehringer

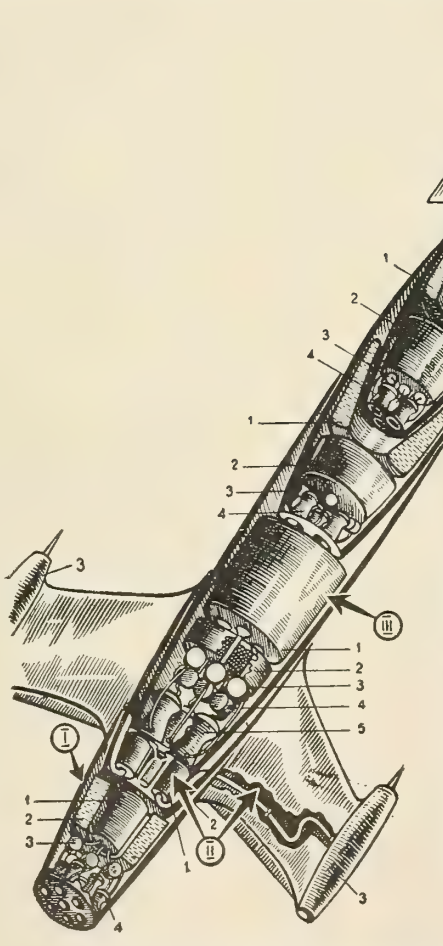
Though the Russians admit they are still far from launching a manned space vehicle, they will almost certainly launch an artificial satellite durin the International Geophysical Year. The best conclusion that can be reached on the basis of the sparse amount of information available to the West is that they are not bluffing. Though it may not get "up there" as soon as the *Vanguard,* when the Red Satellite does settle into its orbit, it may well be heavier—and more exclusive.

The satellite the Russians talk about will probably have recording and fast play-back equipment (see m/r's personal report, this issue) and may thus transmit its measurement only while passing over the Soviet receiving station.

In more detail, this much seems apparent:

——the Russian satellite will be quite similar to Dr. S. Fred Singer's *Mouse* vehicle, making magnetic as well as more conventional measurements.

——It will have a polar orbit, thus enabling it to cover all latitudes and longitudes "while the earth rotates beneath it."



——It will weigh a minimum of 50 pounds, perhaps as much as 100.

——It will be placed in its orbit by a rocket system that is basically the Soviet Intercontinental Ballistic Missile.

Professor K. Stanyukovich, Doctor of Technical Sciences, in Krasnaya Zvezda, August 7, 1955 (as translated by the Rand Corp. for the USAF) wrote as follows:

"The satellite can attain the necessary velocity with the aid of a two-stage rocket . . . if launched at an angle of 45°. When the rocket attains an altitude of 300-to-500 kilometers . . . at the highest point of the trajectory, there must be an explosion which will cast off the sphere to the side of the circumference of the earth with a velocity of eight kilometers per second and thereby convert it into a satellite. Calculations of Soviet scientists, and in particular of Professor G. I. Pokrovski, show that in order to impart the necessary velocity to the sphere, the weight of the explosive charge must be ten times as great as the weight of the satellite itself. Between the satellite and the explosive there must be some inert mass which protects the satellite from the action of the explosion. This mass can be a compressed gas. Undoubtedly, there also can be another, better version of launching the satellite."

That was in 1955. Since then "better versions of launching the satellite" apparently have been developed. This earlier concept estimated that the satellite would revolve around the earth for "several days" before being "retarded

Soviet Astronaut Sedov

by the small amount of atmosphere which still exists at this altitude, (when) it will begin to move in a spiral. At an altitude on the order of 100 km. it will begin to shine and gradually evaporate."

The history of Soviet astronautics extends back before the turn of the 20th Century and first took coherent formalized form in 1903 with the publication of a paper by K. E. Tsiolkovskii entitled "Investigation of World Spaces by Reactive Instruments." Since then the study and contemplation of astronautics has been a respectable occupation. He worked on a concept of "cosmic" rocket planes. Another Soviet pioneer in this field, F. A. Tsauder, suggested that step rockets should be so constructed that the actual structure of each stage itself could be processed and consumed as fuel, thus putting dead weight to practical use.

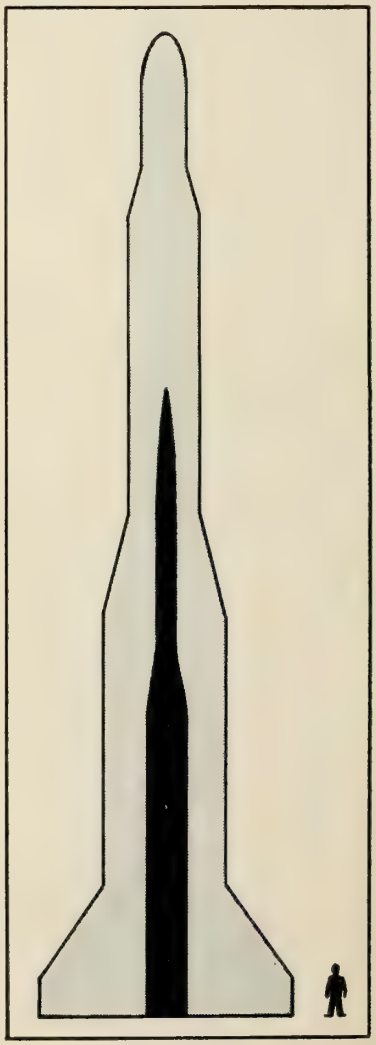
Though it seems pretty obvious that the Russians do not yet have any substantial hardware ready on the firing mat for launching a manned satellite or moon-circling vehicle, the Russians have been thinking about this sort of thing for a long time; one of their forte's appears to be the ability to design and construct massive thrust engines; and in the race for weapons supremacy now being waged between East and West, the advantages of operational space vehicles is obvious.

Furthermore, the Soviet ability to concentrate massive technological and industrial effort without having to answer to the electorate or to consider the needs and wishes of the general consuming public, make the Soviet a place to watch in this connection.

Russian astronautical efforts are now vested in three main groups. There is the purely scientific USSR Academy of Sciences which recently formed the Commission on Interplanetary Communications (Space Flight). The Soviet satellite project operates under this commission. Thus, the project, and its organization, has official government sanction and is on a high level. The respectability of astronautics has been increased by the Tsiolkovskii Gold Medal for Astronautics to be awarded to outstanding scientists.

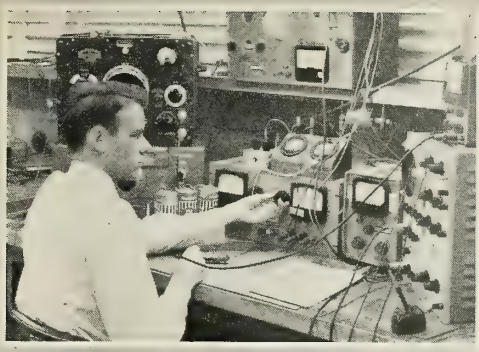
In the middle is the Chkalov Central Aero Club. With headquarters in Moscow, this group is composed of scientists and engineers. The Austronautics Section, recently formed, also belies the official credulence being given to space flight. Presumably, like its analog, the American Rocket Society, Chkalov is a professional society. However, in all probability, it is a buffer group between official sanction and the hardware groups.

Representing hardware are the armed forces of the USSR. It is here that implementation of astronautical efforts becomes less evident. The Reds employ such heavy security here that all references to rockets, for example, are either: very general, foreign developments, or ancient history. Penetrating this veil has been difficult but not impossible. Authoritative sources have outlined a vast rocket and missile effort comparable in magnitude to American developments. Firing an 1,800-mile range IRBM and work on an ICBM are only two indications that the Soviets are near satellite vehicle hardware.



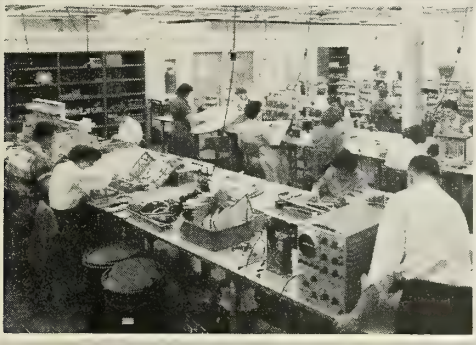
Even more nebulous are references to a Soviet moon project. One version was described in *Pionerskaya Pravda* in 1951. M. K. Tikhonravov of the Academy of Artillery Sciences mentions a 1000-ton circumlunar rocket. The newspaper *Krasnii Flor* (Red Fleet) was later to have said that this rocket was designed to develop 350 million hp and would be 196 feet long, with a diameter of 49 ft. Probably more in keeping with rocket hardware is the description of a one-way moon rocket by Yu. S. Khlebtsevich. The interesting feature of this proposal (first described in *Nauk i Zhizn*) is a "tankette" robot laboratory for exploring the lunar surface.

In checking through Soviet references to space flight, though they sometimes give credit when they quote foreign data and ideas—which is often—it is not always easy to determine just when they are citing or claiming to cite original Russian thinking. However, a quick rundown of some of the propositions they espouse, whether their own or borrowed, gives a pretty good idea of the way they think.



A. G. Karpenko and G. A. Skuridin, writing on the "Contemporary Problems of Cosmic Flights," quote E. Stuhlinger's electrical propulsion system utilizing cesium and rubidium as fuel. He also says that "The problem of utilizing gravitational fields created by the Earth, the Sun, and the planets is absolutely essential for cosmonautics. The fact is that the correct choice of the direction of flight, taking gravitational forces into account, can ensure the ship's motion in space along complex trajectories without significant expenditure of fuel.

Elsewhere in the Rand Corporations "Casebook on Soviet Astronautics" the statement is made that while radar will be useful in measuring distances to and speed by nearby bodies, the space vehicle's velocity relative to more distant bodies may be bettered measured by means of "a special interferometer, which determines the Doppler shift of individual spectral lines.



Soviet writers also suggest that a space ship on returning to earth will begin atmospheric braking of its speed at an altitude of less than 200 km. "The ship will describe around the earth a number of decreasing ellipses whose perigrees are submerged in the earth's atmosphere."

Soviet's IGY satellite is a gigantic project, as seen in view of the superimposed Vanguard.

RESEARCH AND DEVELOPMENT

PILOT LINE PRODUCTION

FINAL ASSEMBLY

TESTING IN SCREEN ROOM

COMMUNICATIONS at Ramo-Wooldridge

Communications activities at The Ramo-Wooldridge Corporation include research, development, and manufacture of advanced types of radio communication systems, ground-reference navigation systems, and electronic countermeasure systems. Major programs are in progress in each of these fields.

New and unusual techniques have been employed to provide systems having a high order of security in the transmission of information, broad flexibility in combating unfavorable signal propagation conditions, and substantially greater information capacity per operating channel.

Some of the techniques used have made possible an increased range for given levels of transmitter power and reliability of communications. Others have provided specific advantages in very long distance communications or in operational situations requiring unique signaling capabilities. Developments in navigation systems have resulted in new equipment that is suitable for the guidance of aircraft at long ranges from their bases.

In the work currently under way, some systems are in the laboratory development stage, some in the flight test stage, some are in production. Several types of systems developed and manufactured by Ramo-Wooldridge are in extensive operational use.

Openings exist for engineers and scientists in these fields of communications activities:

- Systems study and analysis
- Airborne transmitters
- Transistorized video and pulse circuitry
- Airborne receivers
- Reconnaisance systems
- Digital communications systems

FOR HIGHEST STABILITY...

WESTON precision in a metal film resistor...

PRACTICALLY ZERO T.C.

FULL ½ WATT AT 125 C

The Weston VAMISTOR offers you many advantages over wire wound or conventional film resistors, in critical applications. It is a sealed, metal-film resistor that provides greater stability than all previous types. Following are a few of its outstanding characteristics:

- Stable under temperature, moisture and load life
- Stable under vibration, acceleration
- Non-inductive
- Noise free
- Excellent HF performance

As shown on table at right, VAMISTORS meet or surpass MIL specifications. They are now available in the following types:

	INITIAL TOLERANCE	TEMP. COEFF.
Model 9851 — ½ watt at 85C	1% or .5%	± 50 or ± 25 ppm
Model 9852 — ½ watt at 125C	1% or .5%	± 50 or ± 25 ppm
Model 9853 — 1 watt at 70C	1% or .5%	± 50 or ± 25 ppm

all models available in resistance values from 1000 to 100,000 ohms

For complete information on VAMISTORS, return the coupon today.

Rockets Change Modern Army Doctrine

. . . and the Soviets know it

By Major General J. B. Medaris

Commanding General, Army Ballistic Missile Agency

ARMY tatical doctrines are being rewritten as rockets and guided missiles expand the range and increase the lethality of Army striking power. Other nations, including the Soviet Union, have added rockets to their military arsenals and are exploring the potentialities of long-range guided missiles.

Full impact of the revolutionary rocket weapons systems cannot be evaluated at this juncture. But some of the immediate potentialities may be appraised. To do so requires an understanding of Army field organization. Relating this to Korean terrain, which has become so familiar to so many Americans, may be helpful.

Military operations conducted on a large scale normally involve three distinctly separate but mutually inter-dependent commands. In Korea, a Base Command was developed around Pusan on the southern tip of the peninsula. From its boundary north to the combat zone, and spread across the waist of Korea, was the Communications Zone. The Eighth US Army Combat Area extended northward from Inchon and Suwon to the Demilitarized Zone.

Within the Base Command the Army accumulated substantial quantities of supplies: food, clothing, housing materials, automotive equipment and parts, tracked vehicles and all the other paraphernalia required by troops in the field. Smaller reserves of these stocks were maintained in depots in the Communications Zone closer to the using units. In the Eighth Army area to the north, centered on Seoul, were the corps and divisions—the Army's fighting arms.

As operations proceeded, supplies were moved in successive stages; first from the Zone of the Interior or from bases in Japan to Pusan; thence in smaller quantities from Base Command into the Communications Zone, known to thousands of service personnel as KCOMZ; thence to the combat area.

Ground commanders in Eighth Army were responsible to protect their sources of supplies in the rear areas and to defend the Republic of Korea from enemy invasion. To defend their positions they depended upon organic firepower such as the light Infantry weapons, heavy mortars, howitzers and artillery. For far-reaching firepower they called upon the Air Force, occupying fighter and bomber strips to their rear, or the Navy operating planes from carriers off the Korean coast. This type of unified striking power is familiar to any World War II veteran who saw active service in Europe or the Far East.

General J. B. Medaris and Chief of Staff Admiral Arthur Radford at Redstone Arsenal.

While it effectively checked the enemy in Korea, and contributed to the victory of World War II, certain disadvantages inherent in the weaponry involved have long been recognized within the Army. The ground commander was restricted in maneuver within rather narrow limits. His heaviest guns could hit targets less than 25 miles away. Thus he was compelled to keep his artillery well forward. If the enemy's artillery possessed equal range, as must be anticipated, it meant that artillery emplacements were well within striking distance of the foe's counter fire.

We have not yet witnessed the atomic battlefield and hope that we shall never experience it. But the shape of things which might come can be pretty well determined. It would mean vastly greater depth in the combat area, avoiding concentrations of men and materiel, and requiring maximum maneuverability. One can well appreciate, therefore, that if forced to depend upon conventional artillery, the ground commander would present inviting targets to an enemy with atomic capability.

Problems of maneuver and exposure have long since pressed for solution. Exposure, that is, not only of materiel such as weapons and ammunition, armor and transport, but of the troops which serve them and the supporting units which repair, replace and maintain weapons, communications, and satisfy the human needs of the combat units.

Any Army commander well knows that the efficiency of the individual

soldier under stress of combat will inevitably suffer from prolonged exposure to enemy guns.

The role of aircraft in our Army's attempts to resolve these problems is well understood. Organic Army aviation reached new highs in performance during the Korean fighting by spotting targets, checking fire, evacuating wounded, and supplying hard-to-reach points. The bomber and fighter planes rewrote history in World War II and rendered yeoman service in Korea.

But the plane, as a delivery system, has admitted shortcomings. It cannot yet operate in adverse weather, its effectiveness at night is somewhat limited. It is a highly expensive fighting machine to build and maintain. Its crew is normally exposed for relatively long periods of time over hostile territory. What's more, at the higher speeds required to provide more protection to plane and crew, it becomes a less dependable bombing platform under such terrain conditions as were encountered in Korea.

It was to overcome these limitations that the rocket and the guided missile were brought to their present state of effectiveness by the Army with the constant assistance of industry and research agencies. What the guided missile is capable of may be gauged if we again relate it to the Korean situation.

Our ground commanders of the future may call upon such weapons as the *Dart, Corporal, Little John* and *Honest John* for tactical purposes, for greater range and lethality. (Instead of measuring his organic firepower in terms of conventional artillery, he now possesses the means to strike at targets three times as far away.)

Given such a weapon as the medium range *Redstone* ballistic guided missile, soon to become operational, the ground commander can locate much greater firepower at distances many miles behind his lines. From Taegu, let us say, he could launch *Redstone* missiles under any weather conditions, at any time, against targets along and behind the enemy's lines. These missiles would carry warheads with lethality equal to the heavier bombs. They would travel at supersonic speed, subject only to automatic control and guidance carried on board, and could not be intercepted by any known counter measures.

Within the realm of possibility, based upon firm achievements in the art, missiles of greater range will also be available. With these, firepower equal to the Redstone's payload could be directed at hostile targets from deep inside the Base Command.

Still more distant bases may be utilized when our intermediate range ballistic missiles, now under development, join the national arsenal. These missiles, capable of being launched from land or sea, will transport their payloads approximately 1500 miles. Reportedly, the Russians are working on similar weapons.

Thus the modern Army can provide its field commanders with a range of weaponry in rockets and missiles that permits him to apply the scalpel, not the executioner's axe, to borrow a phrase from Dr. Edward Teller, the noted hydrogen bomb scientist. Following our own traditional Army policy, measured force can be used selectively —the right amount, the right time, and right place. The Russians have not ignored rocket and guided missile development in the modernization of their military forces. It can be assumed the Russian Army has put great emphasis on rocket weapons.

Progress in the related fields of rockets and guided missiles will by no means eliminate the ground forces. The Infantryman and his fellow soldier traveling in tanks and armored carriers will be needed to occupy, hold, and possibly fortify terrain. Even in missile warfare, we cannot rule out the possibility of localized skirmishes and engagements with guerrillas or small, roving enemy forces. The ground commander will require troops and planes to locate and identify targets, to determine enemy intentions, and to essay his capabilities.

Korea and European experience of World War II taught us that there will continue to be a need for fighting men to reestablished demoralized civilian populations, to apply friendly controls, to maintain communications, to throw up bridges, to build airstrips and road nets over which to move men, materiel and supplies.

Land warfare revolves around the possession of key terrain points such as road junctions, rail marshalling yards, border strongpoints, and control and command centers. The Army must have the capability to seize and hold these points. It must have, ever-present, the capability of exerting its will upon hostile forces. The new Army makes use of airborne troops and equipment for the rapid exploitation of havoc wrought by long-range firepower.

In the immediate future units of the mobile Army can be transported by organic aircraft. Perhaps in the not-too-distant future, the guided missile may serve another purpose by replacing the freight-carrying plane. For it is my firm conviction that we have entered a new era in transportation. In the giant missile we have a means of utilizing the most efficient and effective delivery system man has yet developed. Within the Army our forward looking planners are considering the guided missile as a potential of great promise with which to deliver all the resources they require for control of the land.

With rocket power as their propulsive system, future guided missiles will rise far above any intervening obstacle, follow a trajectory directly to the target, and put down the forces required to seize and hold such an area within a time span so brief as to defy attempts to prevent their arrival.

This is the era upon which your Army is now entering and which it will aggressively exploit as rapidly as its resources permit to strengthen the national defense.*

[*The views expressed in this article are those of the author and do not necessarily represent Dept. of the Army policy.*]

Shame on the West—practically all "the modern work in rocket technology" outside the Soviet Union represents "purely military effort" and no other. So charges Professor A. A. Kosmodemiansky in his biography of Constantin Tsiolkovsky, the famed Russian pioneer of rockets. This book, issued in 1954 in the same Soldier and Sailor Library series by the Soviet War Ministry, tells Russian troops that "reactive missiles can be hurled any distance," that guided missiles indeed make conventional guns wholly obsolete. Firing from such artillery "over distances of more than 100 kilometers will soon be economically unprofitable." For the walls of such guns have to be "extraordinarily thick and these guns quickly wear out due to the great pressures and temperatures" caused by the tremendous quantities of conventional explosives used in these guns. "How much simpler and more advantageous the modern use of rocket missiles, this very latest artillery!"

ENGINEERS...

CAN YOU SELL YOURSELF?

It takes more than creative ability to be a good engineer. To gain recognition you must be able to sell your ideas to others. More important for success is the ability to sell yourself.

Many positions of technical leadership, some of a supervisory nature, are available at McDonnell just waiting for the right man to appear on the scene. If qualified, interviews can be arranged either in your city or in St. Louis. This is an opportunity to answer the question—can you sell yourself?

McDONNELL *Aircraft Corporation*

MACareers Are Successful Careers

Washington Spotlight

By Henry T. Simmons

A look at the Air Force's new budget readily illustrates the financial bind confronting the airmen. Despite insistence of top USAF witnesses last spring that fiscal 1958 appropriations would have to be substantially increased over those voted for the current year to maintain the current development programs, the new budget embodies reductions rather than increases in two key accounts. For R&D, the Administration asked Congress for $661 million in new money, compared with $712 million voted for the present year. And $1,712 million was requested for procurement of missiles and test vehicles in fiscal 1958, against $1,948 million voted for this year.

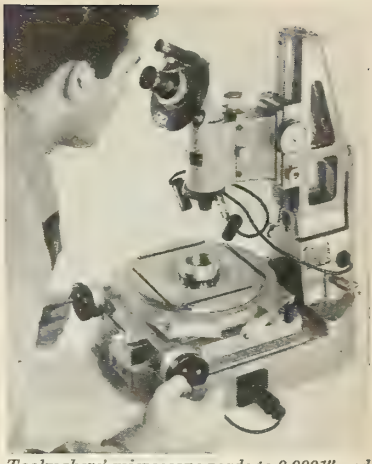
•

If the new money wont be sufficient for all USAF development programs, at least it will assure continued high-pressure work on the *Atlas, Titan* and *Thor* ballistic missiles. Further evidence of the amount of beef behind this program was supplied last month by Maj. Gen. Bernard Schriever when he disclosed that the Western Development Division, in addition to perfecting the hardware, will also assume the initial operational capability for the weapon systems within the USAF. This unprecedented step is deemed necessary for the proper development of the weapon's operational environment and will give WDD control over training facilities and techniques, operational installations, logistic support and other details normally left to the using command.

•

The Northrop *Snark* intercontinental missile appears to have weathered the budget storm in good shape. The weapon is scheduled to go to the Strategic Air Command of the USAF for training and operational purposes, perhaps before the end of fiscal 1958. Though the turbojet-powered *Snark* lacks the speed and altitude of the more glamorous *Navaho,* it has one incomparable advantage: it is here and the *Navaho* is not.

•



The Air Force will support development of the *Jupiter* IRBM project for at least another year as a hedge against the utter collapse of the *Thor* program, according to Pentagon insiders. Still a mystery is where the money will come from. Most likely source: Defense Secretary Wilson's emergency kitty for R&D projects. It contained $68 million at last count, and all three services are in hopes of getting a slice of it.

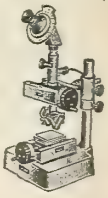
•

"It looked like an atom bomb going off," commented one official after viewing a film of last month's spectacular *Thor* misfire at Patrick AFB, Fla. The big missile hardly cleared the ground before it exploded and drenched the area in a lake of fire. One report blamed the engine for the failure; another said the trouble was up-system from the engine and looked like a valve malfunction. First firing of the vehicle had been delayed for weeks because of leaks and hung valves encountered in static tests.

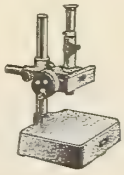
•

Most parties agreed that the *Thor* mishap stemmed from a minor flaw and that the program would not be set back. Nevertheless, there was a disturbing note to the situation. The *Thor* embodies most of the components designed for the *Atlas* and *Titan;* its powerplant is one of the Atlas boosters. Thus any difficulty with the mid-range *Thor* is bound to have ominous implications for the more ambitious weapons which follow it.

Toolmakers' microscope reads to 0.0001" and 1 minute of arc. Co-ordinate range 4" x 2". Compact built-in rotary stage.



Make precise measurements to 0.0001" and cut rejects with Gaertner microscopes



Here are reliable, easy-to-use microscopes for precise, indisputable measurement of piece parts, tools, dies, thread gages, templates, jigs, fixtures, etc. With these instruments you make direct, non-destructive measurements — no contact, no distortion, images are sharp and clear.

Through the engineering facilities at our Chicago plant, these versatile, well-constructed microscopes can be adapted to meet your exact needs. Find out now how you can gain new production savings with Gaertner measuring microscopes.

Coordinate Measuring Microscope

High precision, low cost instrument for 2-dimensional linear measurement. Range 2" x 2", reading to 0.0001".

Micrometer Slide Comparator

Reliable, low cost instrument for linear measurement. Ranges up to 4", reading to 0.0001" or 0.00005".

Scale Micrometer or Shop Microscope

High quality, low cost instrument with range up to 0.100". Reading to 0.001", easy interpolation to 0.0002".

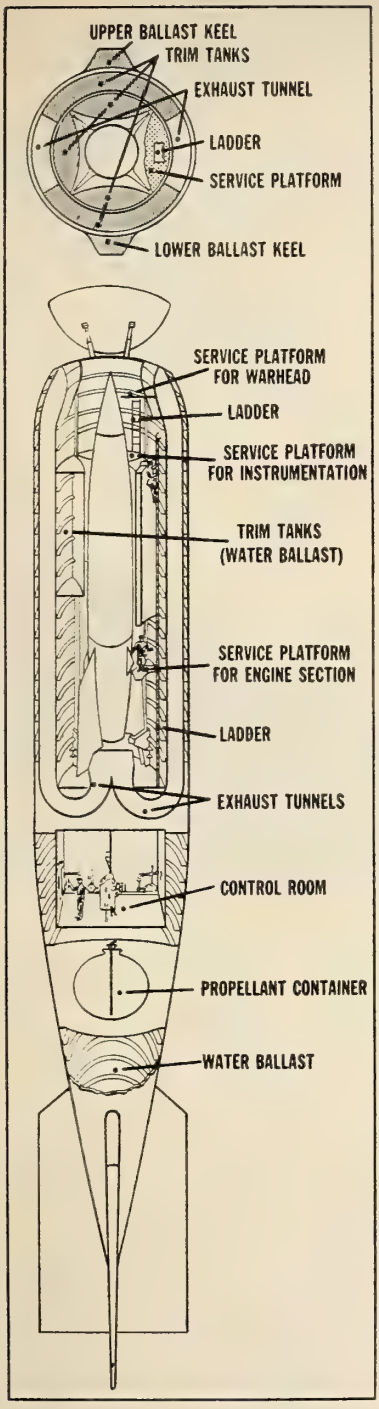
Submarine Missiles: Reds Move Ahead

Ready-to-go solid missile in its launching rack on deck of submarine.

Top U.S. Navy officials have told the House Armed Services Committee that the Russians now have a total of 600 submarines, over a third of the way to their goal of 1,200. This compares to a total at latest official count of 400 for the U.S.

Add to this the *Comet*, Russia's Fleet Ballistic Missile, and the total works out to a considerable threat to the U.S. and it's over 5,000 miles of coastline. Admiral Burke has pointed out that any significant deployment of Russian submarines could well be the tip-off for an attack.



Russian submarines, currently being built at a rate of two-to-three a month, are direct descendents of the World War II German long-range W-class vessels with snorkels for submerged operation and combination diesel-electric powerplants. There are no reports that the Reds have either nuclear-powered submersibles or have gone to the high-speed underwater *Albacore* type of hull. Even with improvements since 1945 it's doubtful if Russian submarines now being built are capable of more than 20 knots on the surface or eleven knots at snorkel depth.

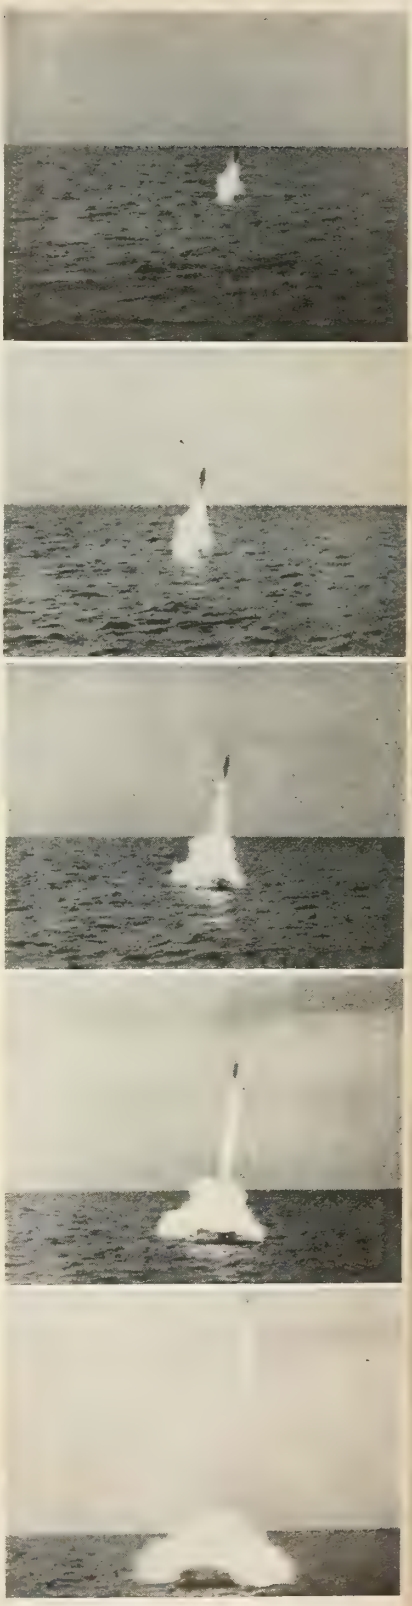
Though there's little reliable information as to the state of Russia's submarine missile art, the basis they started from 12 years ago—two methods for underwater launching worked out by the Germans but never put into actual operation. In the one case small solid-propellant 21 cm *Borsig* rockets were mounted in external racks on the submarine's deck. These could be fired from under water by controls mounted within the submarine. This weapon system now has

Collapsible launching gear for solid rockets being installed on W-class long-range sub. Rack holds six missiles.

Peenemünde left three of these submersible missile launchers to the Russians. Container is 100 feet long, holds V-2-type rocket with propellant supply, control room and water-ballast tanks. Russians also have subs capable of direct launching of fleet ballistic missiles. Russians could tow these containers to undetected sites in the Atlantic or Pacific oceans. Disadvantage of this weapons system lies in the fact towing speed is slow (15-20 knots); sub could easily be detected and attacked by missiles such as our Rascal.

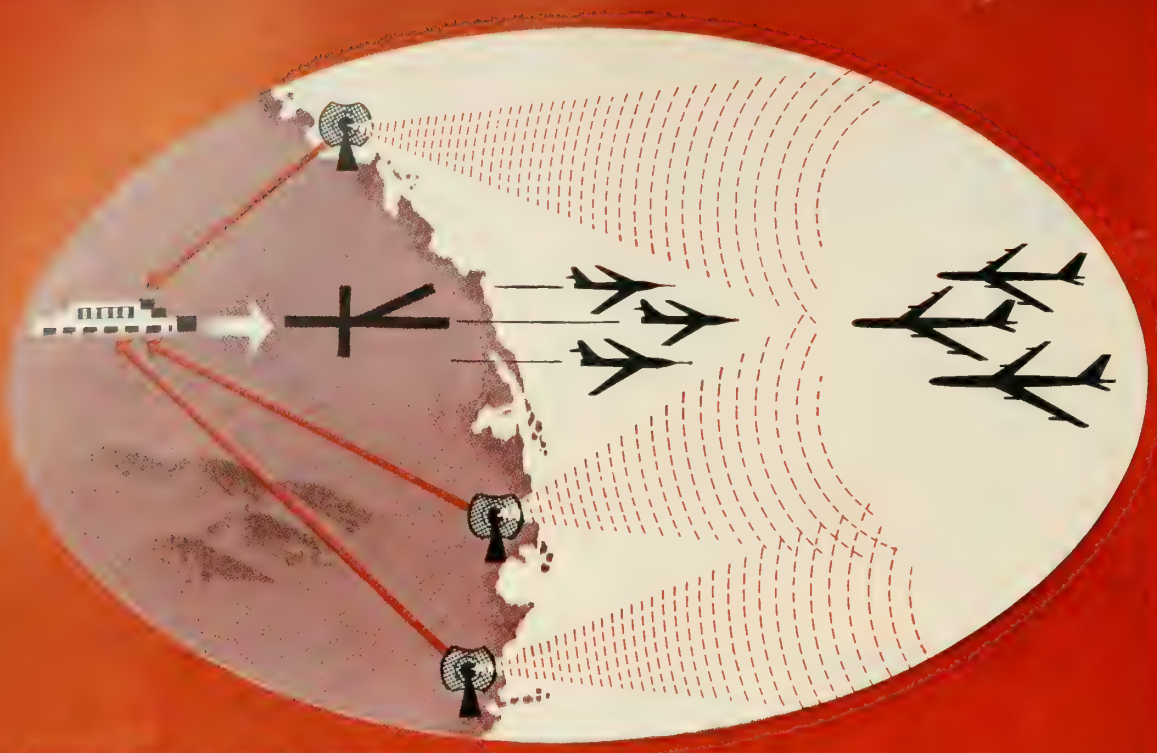
been developed to perfection by the Soviets.

The other method involved the surface firing by a submerged submarine of what basically was a V-2 rocket with a one ton warhead and a range of several hundred miles. There seems little doubt that the Soviet Union must have made considerable improvement in these devices and is now approaching a concept similar to that the Navy envisages for the *Polaris*, namely a 1,000-to-1,500 ballistic missile carried internally in submarines and launched from a fully submerged position. As to whether these are in operation now or not, U.S. Navy Assistant Secretary for Air Garrison Norton says they are not.



U.S. defense against this kind of attack aims first at destroying the submarines before they can launch their missiles. To this end, the Navy has the *Rascal* and, in advanced state of development, the *Lulu*. Development of nuclear warheads in anti-submarine warfare has been a major U.S. project for some time. Later anti-ICBM weapons like the *Nike Hercules* may be able to intercept and destroy these missiles before they reach detonation altitudes.

Meanwhile, the Red submarine fleet and its probable missile potential form the greatest single threat to United States military security. Even though U.S. anti-submarine warfare has reached a high state of effectiveness, it's still far from 100%. And with small-but-powerful nuclear warheads a reality, even 20% of Russia's submarine fleet launching even primitive missiles against our coastal cities could cause severe damage.



It is interesting to note that the Russians have put great emphasis and faith in any weapon system developed by the Germans. In terms of missile systems, all major German concepts seem to have been adopted and accepted fully by the communists, such as the V-2, the *Reintochter*, the *Borsig* solid-propellant sub missiles, as well as the container-hauled V-2s.

Obviously, the Russians had great faith in the Germans and their missile technology and capability; several German scientists have enjoyed high privileges in the Soviet since the last World War. But indications are the Russians are getting tired of playing with German post-war hardware; they have activated several all-Russian missile programs. There is no reason to doubt that an all-out submarine-missile program is heading the list.

Solid rocket zooms out of the Baltic Sea and into the blue skies over Peenemünde.

SAGE

SEMI-AUTOMATIC GROUND ENVIRONMENT

speeds security . . . with the help of Burroughs computation

Briefly, SAGE does this: employs radar and electronic digital computers to detect and identify approaching enemy aircraft; determines appropriate defensive measures such as antiaircraft weapons, missiles, or intercepting planes; guides missiles and interceptors to the target and then returns planes to their home base.

Burroughs has the SAGE job of helping to speed the correlation and translation of warning data through automatic computation. This entails research, development, prototype design and engineering, production, installation, training and field maintenance.

Here is just one of many significant Burroughs contributions to defense in the areas of instrumentation, control systems, communications, electronic computers, data processing. And on the basis of our proved skills, facilities and experience, we welcome further inquiries regarding defense contracts. Call, write or wire Burroughs Corporation, Detroit 32, Mich.

Proposal from behind the iron curtain:

SATELLITES

for checking Einstein's relativity theory

By M. Subotowicz
Physics Department,
University of M. Curie-Sklodowska
Lublin, Poland

As the science of earth satellites develops it may well be possible to experimentally check Dr. Albert Einstein's General Theory of Relativity. In recent years this revolutionary physical concept has come under closer and closer scrutiny by mathematicians and physicists the world over. As more and more empirical evidence of the innermost structure of matter is brought to light, more and more does Einstein's theory seem to fit. Or does it? That is the question.

In using it to explain newly suspected phenomena, the theory continues to provide a great many logical answers. But, there is an increasing suspicion that it may not be the full answer in itself; that parts of it may be wrong or that it simply may be incomplete. Recently, for example, experimental results of work with matter at temperatures close to zero degrees Kelvin raise doubts as to Einsteinian time hypotheses.

If the doubts about some phases of Relativity could be proved or disproved conclusively in controlled man-made experiments it would greatly facilitate the analysis and evaluation of work in the study of matter and the solution of science's basic mysteries, such as the true nature of gravity.

While the early satellites to be launched by the U.S. and the Soviet Union during the International Geophysical Year may not be sufficiently perfected to help in the resolution of these problems, later models may well be capable of providing us with specific answers. These would be satellites able to remain stable in their orbits for periods of a year or more. Some would have to circle the earth at an altitude, say, of 2,000 kilometers with a period of under two hours. They would not necessarily have to be either manned or recoverable. But the means of very precise continuous measurements would have to be provided. And they would be rather larger than presently planned early vehicles.

The General Theory of Relativity is the theory of gravity, time and space as formulated by Einstein. It is the theory of the relationship of the properties of space and time with matter and its motion. The experimental verification of the results of the Special Theory of Relativity is generally not so difficult and has been performed with great accuracy. But experimental verification of the General Theory of Relativity is very difficult.

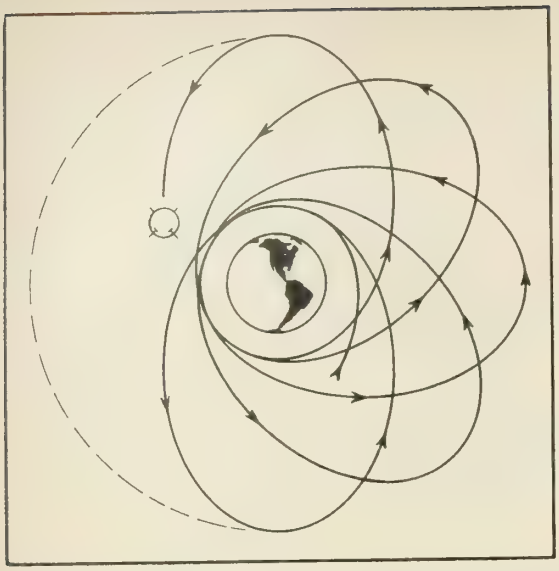
Einstein suggested three effects to prove the General Theory experimentally. According to Einstein these three effects could be measured:

1—the gravitational shift of the spectral lines.

2—the gravitational deflection of light.

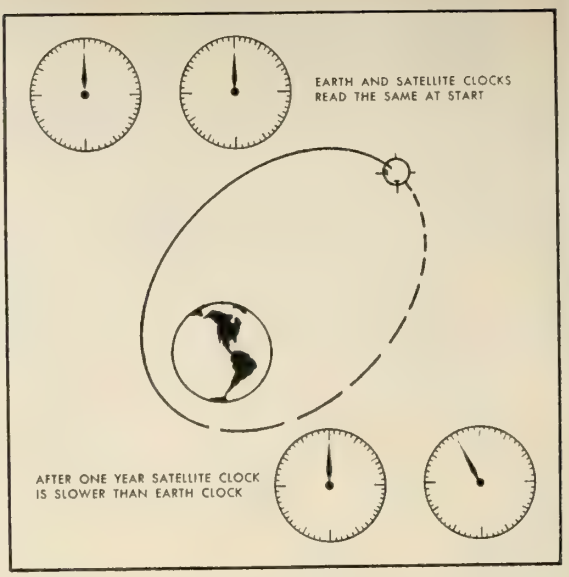
3—the advance of the perihelion of the planet Mercury.

M. Subotowicz is "a scientific worker" at the Physics Department of the University of Madame Curie-Sklodowska in Lublin, Poland. This article, which he has titled "The Artificial Satellite of the Earth and the Possibility of the New Experimental Verification of the General Theory of Relativity," was written exclusively for MISSILES & ROCKETS.



I won't discuss these three effects in detail here. They can be found in special books on the General Theory of Relativity—Tolman, 1949; Moller, 1952; Fock, 1955. I shall give the results of the measurements of the effects proposed by Einstein. Indeed the gravitational shift towards the red of the sun spectral lines and other stars has been observed. The same effect for the massive (companion of) Sirius is about thirty times as large as for the sun.

The gravitational deflection of light was observed in the gravitational field of the sun. The angle of deflection for a ray of light, which grazes the limb of the sun, is 1.75 seconds of arc. This effect has been tested by observations during total eclipses of the sun on the apparent positions of stars. The light of those stars has passed close to the limb of the sun.



The agreement between predicted deflection and the observations would be accurate, except that the shift is just inside the limits of experimental error. This effect can be treated as having been tested only qualitatively.

As the third effect to verify the General Theory of Relativity Einstein has predicted the advance of the perihelion of Mercury around the sun. This he predicted would be at the rate of 42.9 seconds of arc per century. After subtraction of the effect due to the perturbation by the other planets, the observed advance of the perihelion is 43.5 seconds of arc per century. This is in excellent agreement with the predicted theoretical value. The advance of the Mercury perihelion was known before Einstein's theory. That theory explained this effect.

The existence of only these three effects to prove experimentally the General Theory of Relativity shows

The perigree of a satellite orbiting about the earth for a year would, if Relativity calculations are valid, advance more than the perihelion of the planet Mercury does around the sun in 100 years, and might thus provide another check of Einstein's theories.

According to time lengthening theories in Einstein's General Theory of Relativity, a clock in an earth satellite would run more slowly than one at relative rest on earth. Subotowitz says the difference in a year could be measured with available equipment.

that Newton's theory represents a good approximation for all gravitational phenomena inside the solar system.

Two Out of Three Verifications

In the use of an artificial satellite for verification of the General Theory, only two of these three effects are of importance. They are:

1—the gravitational shift of the frequency of electromagnetic wave radiation (from the satellite) in the gravitational field of the earth.

2—the advance of the perigeum of the satellite orbit in its motion around the earth.

But there are yet two more relativistic effects to prove the General Theory. It is impossible to verify these by observing known celestial bodies. They are:

3—the relativistic "effect of rotation" of the spinning central mass (earth) on the advance of the perigeum (perihelion) of the satellite (planet). The influence of the Lense and Thirring (1918) predicted "effect of rotation" on the advance of the Mercury perihelion is very small—only —0.01 seconds of arc per century.

4—the lengthening of time on the artificial satellite moving in the gravitational field. This effect is connected with the General, not the Special Theory of Relativity.

I shall give here some results of the calculations of all these effects in connection with the problem of artificial satellites (Ginzburg, 1956; La Paz, 1954; Winterberg, 1956).

Suppose that the height of the satellite orbit above the earth is $h = 800\ km$. Then the relative change of the frequency of radiation emitted by the satellite and observed on earth would be

$$(\Delta^{\nu}/_{\nu})_{gravit.} = 7.6\text{x}10^{-11}.$$

Since the source of the radiation, the satellite, has a smaller gravitational potential than the receiving station (the earth's surface), the observed shift of the electro-magnetic radiation should be the violet shift. It would not be a red shift, as in the case of the sun or another star.

But the relative shift of frequency connected with the Doppler effect is of the order

$$(\Delta^{\nu}/_{\nu})_{Doppl.} = -3\text{x}10^{-10}$$

for this same satellite. Thus, the Doppler effect shift is about four times larger than the gravitational shift.

It is, unfortunately, impossible to separate these two effects in one experiment. Thus experimental verification of the General Theory in this way is quite difficult. Life would be considerably simplified, however, if the satellite were circling along a much higher orbit, where h is greater than the radius of the earth.

Advance of Satellite Perigeum

For the above-mentioned satellite, the advance of the perigeum as a consequence of the influence of the gravitational field of the earth is quite large, about 1500 seconds of arc per century. This is about forty times greater than for the Mercury perihelion. According to La Paz (1954), a one-year observation of a satellite would be more efficient than a 100-year observation of Mercury.

According to the theories of Lense-Thirring (1918), there is an effect of the spinning central mass on the perigeum motion of the circling body. For the Sun-Mercury system, this effect is very small, hardly —0.01 seconds per century. For an artificial satellite circling at a height $h = 400\ km$ above the earth with a period $T = 1.54\ hr.$, the advance of the perigeum as a result of the earth's rotation would be about —43 seconds of arc per century. Thus the gravitational effect of the rotation of the earth would be as great for the satellite as relativistic effect on perihelion advance appears to be for Mercury.

The effect here discussed is connected with the General, not the Special Theory of Relativity. It concerns the Doppler effect in the presence of gravitational fields. And with the Doppler effect is connected the analysis of the time on earth and on the satellite.

The General Theory of Relativity treats with both longitudinal and transverse Doppler effects. The transverse Doppler effect is indirectly connected with time-lengthening and is not dependent on the direction of the motion

of the radiating body (the satellite) relative to the observer. As time passes the difference in the readings of two watches, one on earth and the other in the satellite, will grow in accordance with the above-mentioned transverse Doppler effect. In the General Theory of Relativity there are formulas dealing with the ratio of the time intervals of two synchronized watches in the reference systems of emitter and observer.

Neglecting the small influence on the earth's rotation on time lengthening, the following simple expression for the ratio $\Delta t/t$, where Δt is the difference of times measured on earth and in the satellite and t is the time measured on earth.

$\Delta t/t = A/r_2 - 3a/2r_1$; $a = G.M./c^2$

Where r_1 is the radius of the satellite orbit measured from the center of the earth; r_2 is the radius of the earth; G, the gravitational constant; M the mass of the earth; and c, the velocity of light.

According to Winterberg (1956), for a satellite at height $h = 1650$ *km* above the surface of the earth is $\Delta t/t = -1.3 \times 10^{-10}$. This means that in one year, a watch in the artificial satellite should be 4.2×10^{-3} seconds late relative to the watch on earth. A watch with an accuracy of 10^{-11} could be used to verify this effect. The "atomic watch," with an accuracy of 10^{-12} would meet these requirements.

Thus the coming of the artificial satellite offers the possibility of yet additional scientific work of the greatest importance. It should be noted, however, precise measurement of the effects of interest (rotation effect and time lengthening) will require a precise knowledge of all deflections from the stable satellite orbit. Some of these deflections include: the perturbations of the sun, moon and the other planets; the inhomogenity of the earth's mass distribution, the resistance (of the rests) of the atmosphere, tide effects.

Aerophysics

By Seabrook Hull

The U.S. is well on the way to overcoming Russia's reported lead in high-energy particle accelerators used in the basic study of matter. Prof. Luis W. Alverez (Cal. Tech.) used such equipment in the mu-meson "cold fusion" of light and heavy hydrogen into helium, the first real break in man's efforts to develop a controllable thermo-nuclear rocket motor.

Dr. Tihiro Ohkawa and Dr. Lawrence Jones of Midwestern Universities Research Association reported before the American Physical Society on a "siamese twin" accelerator design to give a useful energy release of 30 billion electron volts. Proposed are a pair of backed-up 15 billion e.v. accelerators whose proton beams intersect. To achieve this power by conventional stationary target machines would require a theoretical capacity of 540 billion e.v. Largest accelerator in the U.S. is the Bevatron at the University of California at Berkeley with a useful power of two billion e.v. A six billion e.v. machine is now under construction at Brookhaven National Laboratory, reportedly to be on a par about with Russia's best.

•

The Forty-second Annual Report of the National Advisory Committee for Aeronautics gives a new lease on life to transpiration cooling as a possible answer to aerodynamic heating; seems this kind of cooling tends to move the boundary layer separation point downstream. The NACA report also notes detailed investigation of several of the so-called exotic fuels including octene-1, aluminum, aluminum-octene-1 slurries, magnesium, magnesium-octene-1 slurries, diborane, pentaborane, boron, boron-octene-1 slurries, hydrogen, alpha-methylnapthalene, and graphite. In the field of high temperature lubricants, NACA Technical Note 3657 gives data on graphite and mixtures of graphite with lead oxide, cadmium oxide, sodium sulfate, or cadmium sulfate as solid lubricants. Among the temperature tolerant structural materials covered by NACA during the last year are melamine-resin glass-fabric laminates and silicone-resin glass-fabrics—up to temperatures of 600°F. And what may perhaps be a significant note in the incremental stey-by-step approach to manned space flight, this comment: "Because of the loss of the X-2, the need for earliest possible completion of (the X-15) has become imperative." Manned flight testing of superthermantic flight is now limited to a little over Mach 2.0 in the X-1B and X-1E.

•

As man's operational devices depend increasingly on a working knowledge of the basic structure of matter and energy and on clear comprehension of advanced theories such as Einstein's General Theory of Relativity, "major technological break-throughs" are more impressive; their attainment, more difficult. It might help if more people understood the basic theories that have superceded the classical concepts of Newton, Gallileo, Euclid, etc. For the non-physicist, "The Evolution of Physics" by Albert Einstein and Leopold Infeld (1938, Simon & Schuster), covers field, realtively and quanta; is simple, thought-provoking.

•

A Russian scientist claims he has studied chemical reactions at pressures up to 500,000 atmospheres in the laboratory; at 100,000 on the pilot plant level—both records, if true. At these pressure levels, classical chemical and physical laws do not necessarily apply, due to resistance of atoms to compression.

Major and vital components for jet engines

produced by Fairchild Engine Division—*in mass quantity, to highest precision standards*

Through skill, experience and production efficiency, Fairchild Engine Division manufactures such precision parts as turbine wheels, frames, diaphragms and turbine buckets for the jet engines of some of America's most powerful fighters and bombers. Subcontracting many other parts as well, Fairchild Engine Division has proved dependable production performance in mass quantity to highest precision standards.

Now in Fairchild's new plant at Deer Park, Long Island, this production capability is increased even more, and will be put to work wherever necessary to serve today's ever expanding aviation industry.

Soviet Missile Science Profile

. . . from Dr. S. Fred Singer, *Physics Professor, Maryland University*
Dr. Leon Trilling, *Fluid Dynamics Research Dept., M.I.T.*
Dr. Hurd Willett, *Professor of Meteorology, M.I.T.*
Michael Michaelis, *Phycisist, Arthur D. Little, Inc.*
Dr. Albert Parry, *Chairman, Russian Studies, Colgate.*
Alex G. Korol, *International Studies Institute, M.I.T.*
Andrew G. Haley, *Director, International Astronautics Fed.*

Catching its interviewees in between on-time airliners, skiing dates, mid-year exams, baby-sitting chores and book deadlines, m/r's editors traveled hundreds of miles with recorder and camera to bring you this intimate profile of the men and methods of Soviet Missile Science. The better we know them, the better our chances of staying ahead in the current race for missile supremacy.

Soviet Satellite Plans Sophisticated; Astrophysics Research Well Advanced

Q. *Dr. Singer, can you tell us something of Russia's plans for launching an artificial earth satellite?*

A. Dr. Leonid Sedov first announced in 1955 at Copenhagen that Russia would launch a satellite during the International Geophysical Year. This was repeated by Bardin at Barcelona. Last year in Rome, Sedov gave some details; said that their satellite would measure pressure, temperature, density and magnetic field. I questioned him rather closely as to whether they were really going to measure temperature, to which he replied, no. To measure temperature under satellite conditions is very difficult.

Q. *Did he indicate the size of their satellite?*

A. No. But when I asked him whether they were going to measure magnetic fields, he said yes. This gets into size because you have to provide storage equipment and you have to play it back in order to transmit it when the satellite is over the receiving station. Play-back must be at a very rapid rate, and therefore with high transmitter power which means several watts. This rules out transistors. It also requires the use of B + batteries. This really adds weight.

Q. *Have you done a rough calculation of what the minimum weight would be?*

A. Yes. I would estimate it's at least 50 pounds, if they want to measure magnetic fields in the proper way. Properly packaged, it could still be fairly small, however. My guess is that the Russians will have a satellite with a near-polar orbit or an orbit which is much more inclined than ours, and with internal recording and playback. It's a more sophisticated satellite than our first ones.

Q. *Did Dr. Sedov make any claims as to how long it would stay in orbit?*

A. No, he didn't, but of course with sufficient propulsion in the rocket assembly, you can make the satellite stay in its orbit indefinitely. In an orbit at about 400-to-500 miles instead of 300 miles, the chances of long life are enhanced quite a bit. And from some indications, particularly in your magazine, it seems like they have the rocket equipment to do such a job. But of course this doesn't mean they can do it immediately. It still takes some work. It takes some thinking, as Bardin said.

Q. *Do you think they're bluffing on the satellite?*

A. In a Western Gear advertisement in the Wall Street Journal, Mr. Bannon, the President of that firm, raised the question of whether they've got a satellite ready for launching or whether they're just bluffing. As you know, they copied the Mouse. The question is: Are they bluffing and just covering up by printing this picture from Popular Science, or was the artist just lazy and looked around for something that looked like a satellite to put in the article. I think it's probably the latter. I don't think we should underestimate the Russian effort.

Q. *Wasn't the Mouse your idea?*

A. Yes. It is a more sophisticated satellite than the Vanguard and I think it would have come first except that the Vanguard propulsion system is fairly limited.

Q. *Can you give any indication of the level of Russian science in the fields with which you're familiar?*

A. In astrophysics and in cosmic rays the Russians have done outstanding work on the theoretical side and fair work on the experimental side. They've made some very important discoveries, particularly in the field of radio astronomy and have done a great deal of theoretical work of some importance on the origin of cosmic rays. You can say they have contributed to the world's supply of knowledge. The reason for such a great amount of activity in theoretical astrophysics is twofold: First, you can learn a lot about the universe, which has great scientific interest. Second, the energy sources in the universe are based on fusion power, and the more we learn about how the universe operates, the better we can understand fundemental physical laws.

Q. *Would their knowledge of astrophysics contribute to their work in nuclear physics?*

A. Not necessarily, but they do have excellent theoretical nuclear physicists. There is great incentive for Rus-

sian young men to go into the natural sciences. I think the incentive is partially financial but most of all a matter of prestige. And, the support they get for their work is just tremendous. Russian cosmic ray physicists may have fifty assistants working on data, reducing results, laying out experiments and so on. This is a tremendous number compared to our average large cosmic ray group of that type which might have, maybe, five assistants. They just don't care how much money they spend and as a result often spend it very uneconomically and wastefully. And, as well as the men, they have some good equipment. Our nuclear physicists who have been over there are very impressed by their large accelerators. They are well engineered. So apparently they're developing a good crossbreed team of pure scientists and engineers, which is of great importance. Their system of technical education is quite excellent and heavily endowed. Some Russion scientists I've talked to have graduate classes with maybe a couple of hundred students where we have only a few.

Q. *In your field of physics do they tend to quote American and other foreign figures rather than their own?*

A. They always cite their own calculations and prolifically. I think this is part of the way they operate. But when it comes to experimental results, they pretty much have to fall back on Western figures. They don't have the experimental data, but they're good interpreters.

Q. *Does this mean that they tend to take their lead from non-communist sources, and then, once they know the basic problem, to tackle it on an all-out basis?*

A. This is not always true. Sometimes they take on experiments themselves which are quite difficult and expensive and not very inspiring. This is because they are not in close touch with the Western world and don't keep up. In some fields they are completely out of fashion. In others they are right at the forefront.

Soviet Scientists Competent, Sociable; Missile Hypersonic Knowhow Up to Date

Q. *Professor Trilling, what is your experience with Russian science and scientists?*

A. I have looked at their education system in aeronautical engineering. Also, as a practicing aerodynamicist I follow their technical papers. I have talked with acousticians who attended the Second International Acoustics Congress here at MIT last June, and to aerodynamicists at the International Congress of Applied Mechanics in Brussels.

Q. *Were they easy to talk to?*

A. Oh, yes. They were trying to contact all the people they had heard of in the U.S., trying to find out what they were up to and quite willing to say a good deal about what they themselves were doing. Whether or not they were telling everything is hard to say. They were quite willing to talk, though this depends a bit on the individual. One senior gentleman who came up the hard way was very skillful at evading questions whereas another one a little bit younger and with a different personality was only too anxious to talk—was going out of his way to find people to talk to on the technical problems he was interested in, what his ideas were and how he was going about it. In fact at times, the older one had his hands full trying to keep the younger one from talking too much.

Q. *Did you get the idea that their level of accomplishment was on a par with ours?*

A. On the average, the answer would be yes. In some areas they're doing possibly better than we; in others we are doing a good deal better.

Q. *Did they describe their research equipment?*

A. No. In fact they were fairly careful not to talk very much of their research equipment. Professor Leonid Sedov said the volume of experimental work in the USSR was a good deal lower than in this country, so that they were attempting to use their facilities as effectively as possible. I have a feeling that they are not too active in fundamental experimental research, but they are extremely strong in analytical research.

Q. *With regard to education, what is the significance of reports that they're graduating increasing numbers of engineers? Do they simply order a promising student to go into, say, aerodynamics?*

A. Well, no. It isn't as crude as all that. The carrot gets you much farther than the stick. There are all sorts of incentives. In the first place there is no equivalent in the Soviet Union to our class of administrators and executives. The technically trained people do that work. They are the socially leading groups. So there is an inducement for them to go into natural and applied sciences. And, a student in aeronautical engineering, for instance, will get a bigger fellowship than a student in history or ancient languages. The number of applicants for the better technical schools is a good deal higher compared to vacancies than the number of applicants for schools which train librarians and such. Students are not told what department they should register for individually. Still, the total number of students in various fields is regulated. It is decided by the Government that 65% of college vacancies will be in the natural sciences. In this country, I think this is correct, about one in eight children eventually go to college. In the USSR it is likely to be one in twelve. A greater proportion of these are in the technical fields.

Q. *In talking with Russian scientists, did you ever get the impression they were trying to pump you?*

A. It depends on the individual. Without quoting names, I would say that some gave me the impression of trying to get the most information at the least cost in contributions by themselves. Others, on the contrary, spoke freely and were apparently quite willing to talk about their own work.

Q. *Can you be specific as to the state of the missile art in Russia?*

A. In theoretical work they are extremely good. It's in experimental work where they are not so good. In the theoretical work I think they are at least as good as we, apparently having spotted some problems a few years ahead of us. Exactly where they are now is difficult to tell because of security and that sort of thing, but they seem to know what they are talking about, and they grasp the fundamental problems involved in hypersonic flow past a missile-like configuration. They know how to go about making reasonable calculations. So far as the boundary layer is concerned in hypersonic flow—the bow shock wave and pressure distribution—they gave a paper about a year-and-a-half ago at a meeting in West Germany that thoroughly indicates they know how to calculate pressure distribution of a sharp-nosed body as well as a blunt body in hypersonic flow. And the comments they make indicate they are not only interested but reasonably well advanced.

As to heat transfer, all I got from them was that there is a group doing experimental work on heat transfer and presumably doing all right. At any rate they know what the heat transfer problem is. Not very long ago, a paper

was published by L. E. Kalikhman, who has been doing high speed boundary layer research in the USSR. He wrote on the reduction of heat transfer through a boundary layer by injection of a cold, light gas through the wall. This is a technique with which we are also playing. It shows that they know what they are about. However, how well they are succeeding is hard to tell because the experiments which Kalikhman quotes to support his calculations are American measurements.

Q. *Why did he quote American measurements?*

A. I think this is standard procedure with people associated with defense establishments. But people in the power stations ministry, for example, who also do gas turbines, publish local data quite freely . . . interferograms of high speed flows past cascades, heat transfer measurements, boundary layer profiles and all sorts of things, because, I suppose, this is a research establishment of a non-sensitive industry. It raises the question of whether people in one industry talk to people in another.

Q. *Could you name some of the outstanding people in Soviet aeronautical engineering?*

A. I think the two leading men in fluid mechanics are Sedov, who is the theoretician, and S. A. Christianovich who did important work in transonic flow in the late 1930's and early '40's and who is now Secretary of the Engineering Section of the Soviet Academy of Sciences. As such, he has much to say about what type of engineering research is done.

Q. *Have you seen any signs that scientific theory is still politically dictated?*

A. Not in any of the aeronautical sciences.

Q. *They are competent competitors, then?*

A. They're quite competent, but they're rather dedicated to the state. They have a measure of national fervor which makes them very intense and hard working. They believe in Soviet science, not science in general—a factor that's just a bit disturbing.

Q. *You mean the advantage it may give them?*

A. Whether this really is an advantage in the long run is a question. It leads to an approach to scientific research which is a little bit too much day-to-day, a matter of concentrating on today's problems today and letting tomorrow's problems get solved tomorrow. A disadvantage is that the right fundamental problem may not be attacked early enough. It does have the advantage of concentration of effort. But it makes them sometimes rather forbidding.

Soviet Theoretical Work Excellent? Engineering Crude; But Results Good

Q. *Mr. Michaelis, you were at the U. N. International Atomic Conference at Geneva in 1955?*

A. Yes, I had submitted a paper and attended as a participant though not a formal delegate.

Q. *Being British, were you in a better position to talk to the Russians than the Americans?*

A. No, I don't think so. Having lived in America for the previous 5 years, I was not regarded as a member of the British contingent anyway. Generally speaking, it was notable—for the first few days anyhow—that quite a few Americans held off from talking with Russians—and vice versa. Europeans seemed to get to them more quickly, one reason possibly being that many of the elder Russians spoke German, having studied in German universities before World War II.

Q. *Well, in talking with them, were they just like any other group of scientists, anxious for information and willing to contribute fully to the discussion?*

A. Curious and interested, but a little hesitant, I think, at least to start with. The first few days were pretty formal. Then things began to loosen up a little. They mixed well, barring the language difficulty. I got the impression they were holding back on information, because on direct questions such as "where do you get your uranium"? you'd get no answer, or you'd be told "Well, it's sent to us."

Q. *Could this have been all they knew?*

A. One would guess they knew a little more. They were obviously working under fairly strict instructions from home on what to say and what not to say.

Q. *Any more strict than ours were, for example?*

A. That is hard for me to tell. I don't precisely know what our delegates' instructions were. One of the interesting aspects of the Conference, in retrospect, was their exhibition of equipment which showed that even though they were scientifically well advanced and knowledgeable, their technical execution was much less elegant than ours. Instruments and equipment they showed had an archaic look. But from experimental results obtained with them and presented at the Conference one must assume they function perfectly well.

Q. *Do you think their technical achievement in the field compares to ours?*

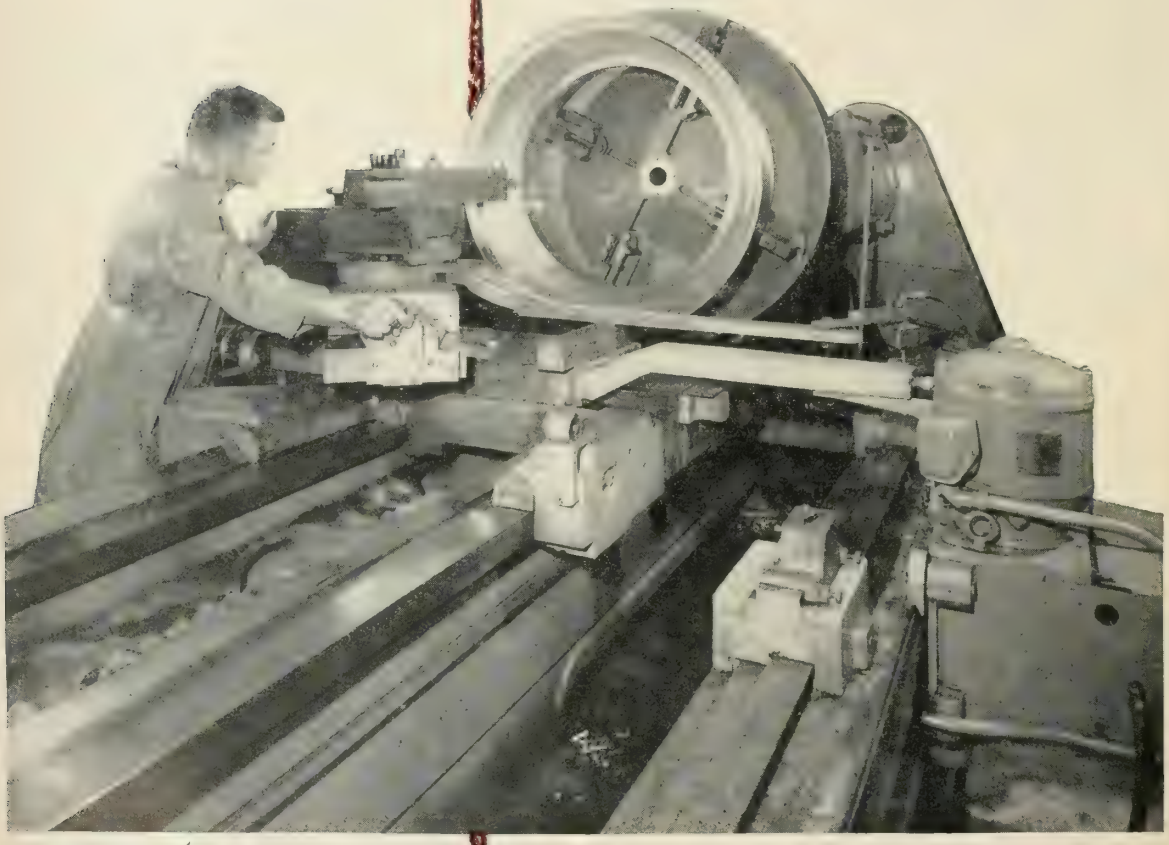
A. You must distinguish clearly, I think, between technical and scientific—applied as against fundamental research. I would think that in fundamental research they matched us quite well. As far as applied engineering goes, their proposed power station, medical radiation equipment, etc., I think they did not match our standards in sophisticated design work. It seemed a little like what in England used to be called the "string and sealing wax" style. As I say, it's only appearance, and it's very hard to judge from looks alone the reliability of a nuclear power station or whether an instrument is better or worse.

Q. *Did you get the impression that, as scientists, they felt a serious lack at having been unable to wander about the see what the rest of the world was up to in nuclear technology except through translated papers?*

A. Yes. Some said that in so many words—in private conversations They seemed to feel this a handicap, but so did delegates from other nations, bearing in mind the tight secrecy prevailing at least up to Geneva.

Q. *Considering the level of know-how required for early nuclear powered aircraft, what do you think of the state of their art?*

A. This, of course, was not discussed in public, nor privately to the best of my knowledge, being a highly classified area. But, knowing their achievements with large aircraft gas turbines and knowing that as far as nuclear electric power plants are concerned they are not very far behind us on the fundamentals. I would think they are capable of achieving nuclear aircraft propulsion. Extrapolating from their past performance, they certainly seem to have the brains and technical capabilities of solving these problems. Western delegates were surprised in Geneva at how far they had got in their fundamental understanding of nuclear technology. And, in the case of the controlled thermonuclear reaction Academician Kurchatov made a speech last April at the Atomic Energy Research Establishment in England that gave more information on the subject than any nation to that time.



Kurchatov said at the time that the "pinch"

Missile Metal Machining

The picture below shows a guided missile component of A-286 alloy being machined on a 48" Monarch Air Gage Tracer Lathe at Diversey Engineering. Nowhere else can you get such extensive facilities for contour machining of Titanium, Inconel, A-286, Haynes Stellite and Zirconium.

LARGEST FACILITIES . . . exclusively devoted to your Guided Missile, Rocket, and Jet hardware problems in missile metal machining. Currently in production are accumulators, nozzles, nose sections, bulkheads, rings, cones, and rocket motor parts, all of them involving intricate and difficult machining techniques.

Write or phone for information on your designs and blueprints.

LEADERS IN CONTOUR MACHINING

Diversey ENGINEERING COMPANY

10257 FRANKLIN AVENUE • GLADSTONE 5-4737

Circle No. 6 on Subscriber Service Card.

effect, using electro-magnetic fields, was probably not going to be the ultimate way of achieving controlled mononuclear reactors. He could see limitations. I would think that we've already seen them also. The cold fusion reaction might be a possible alternative approach. At least, Dr. Alvarez of the University of California recently announced the discovery of a low temperature reaction, using a mumeson as a catalyst, to fuse hydrogen and deuterium. It is interesting to note that Dr. Alvarez mentioned that a Russian scientist had predicted the possibility of this reaction some two years ago—another indication that they do not seem to be lagging in ingenuity.

Since particle accelerators are said to be a possibly significant tool in achieving thermo-nuclear reactions, it is interesting to note that, as far as accelerators were concerned, the Russians appeared to be ahead of us in some ways at the time of Geneva. Some visiting U.S. firemen felt that Soviet multi-billion volt accelerators seemed to be further advanced than those in the U.S. So for research in this particular field they may be as well, if not better set than we, for the time being at least. It takes time to build these machines, and they started a bit earlier.

Q. *Did you get the impression that perhaps they lack in experimental ability?*

A. No, I don't think I did. Their experimental work, even though it may sometimes appear crude to our eyes, has certainly produced results which are identical to ours. One of the highlights of the first few days of the conference was the simultaneous release by the U.S., Britain, and Russia of certain so-called n e u t r o n cross-section properties of materials. These had been obtained independently and kept secret until then. The three curves fell on top of one another with remarkable agreement.

Q. *Did you feel that they had gained a considerable degree of scientific intellectual freedom?*

A. Well, more than they've had, I think, until recently. Perhaps they don't have as much as they want. I believe that only a few weeks ago scientists formally asked the Soviet Government for more "scientific" freedom.

Q. *Going back to the reticence of American scientists during Geneva's first few days, do you feel we would gain if more U.S. scientists and engineers traveled abroad to international conferences and the like?*

A. Yes, I do, very definitely.

Red Atmospheric Theory of Little Value; Loss in Translating Technical Papers

Q. *Dr. Willett, what is your experience with Russian science and scientists?*

A. I knew Commander Ryzhkov who was liaison man between U.S. and U.S.S.R. meteorologists during and after the war. I also talked quite a lot with the chief Russian long-range forecaster, Col. Pagava, who was over here at the same time. Otherwise, I know Russian scientists only by personal correspondence, exchange of reprints, etc.

Q. *How deeply do they go into the study of the atmosphere? For example, are they knowelgeable on the degree of dissociation at altitude?*

A. The Russians have done something with ozone, but I don't think that's a specialty of theirs. I would say that Soviet meteorological work has not been primarily of basic importance. They do a tremendous amount in observational and applied meteorology, maintaining large systems of observational stations, and particularly in Arctic meteorology. They have developed some forecasting theory, but their contributions, as far as they're generally known, don't rank with British and Scandinavian meteorology.

Q. *Are their professional papers, when translated, technologically thorough, lucid, etc.?*

A. That's hard to answer, for the language presents certain difficulties in translation. It's a question of whether the translated product means as much to one of us as it did to the Russian.

Q. *Why is this?*

A. They have different ways of saying things. In fact, it goes almost back to a different way of thinking sometimes, and it's pretty difficult always to get an exact equivalent . . . whether from Russian to English or vice-versa, some of the finer points may be lost in translation. I think this is something anybody reading translations of Soviet technical papers should keep in mind. I've studied the Russian language sufficiently that I am aware of differences in grammatical structure and different ways of using verbs that sometimes make the exact rendering of the meaning in the other language awkward. However, despite this handicap, they study very thoroughly all the literature of other countries. In fact, a lot of what you might almost call textbooks are taken from German and American meteorologists.

Q. *Though their efforts at developing meteorological theory haven't been too successful, in other than theoretical work have they made any material contribution to the science, such as in measuring and observational techniques?*

A. Though they developed their own radiosonde about the same time as Finland, I don't think there's a great deal that we have that we wouldn't have had if it hadn't been for the Russians. They've given much information, however, particularly in Arctic meteorology.

Krushchev, Bulganin Chide Scientists; Ballistic Rocket Threat is Not a Bluff

Q. *Dr. Parry, considering all the facets that make up a complete and whole scientist, are there any gaps or lacks in the Soviet scientist?*

A. Well, one is the lack of personal communication with the West. Up to and including Stalin's demise, the Iron Curtain did Russian science more harm than it gave Russian science any security from Western prying and spying. Because Soviet scientists were cut away from Western science so completely, they are not as far ahead as they could have been. There is still some fear on the part of Russian scientists apparently of being in touch with the West, and their leaders, Krushchev and Bulganin, have to remind them from time to time, sometimes in rather crude and rude words, that they have the Kremlin's blessing for making contact with the West. Last February during the 20th Congress of the Communist Party, K & B both chided Russian scientists for being so slow in getting in touch with the West. Apparently K & B feel that if intercourse is allowed, we in the West will learn less of value from the Soviets than they will learn from us. Security is desirable, they said, but not so as to isolate Russian science.

K & B also said that Soviet scientists hide too much from one another. Krushchev put it this way: ". . . too much pointless, parallel work because one group of scientists do not know what another group of scientists is doing." Another point of chiding was that there is too little of the very necessary connection between industrial and university research. "Look at the United States," said K & B, "where universities do so much research for in-

dustry, where industry helps universities, gives them grants, establishes laboratories. Such collaboration is very necessary for the advancement of science and should be emulated in the Soviet Union." Another point of criticism K & B advanced to their own scientists and engineers is that there is too much nepotism, too much favoritism to their own families and to friends of friends of friends.

Q. *Haven't they got a slang word for that?*

A. Blat. Blat covers a multitude of sins. Sometimes it's also called left-handed business, meaning that your right hand pretends not to know what your left hand is doing. It also means illegal; and profit for the individual rather than the state. Another point of Soviet criticism of their scientists, one which has been repeated again and again in the Moscow press, is that Russian scientists like comfort too much, that they have established their institutes in Moscow and Leningrad and do not go into the field. The reindeer breeding institute is in Moscow and not in the Arctic; Marine institutes are in Moscow instead of by the sea. More than one third of all institutions and laboratories run by Soviet industry and two thirds of those belonging to the Academy of Soviet Sciences are concentrated in and around Moscow and Leningrad. Why? K & B say because scientists, their assistants and their families like the soft life, bright lights and comforts of big cities. So the order now is to disperse. Of course, this may be a camouflaged desire to disperse the institutions in case of war.

Q. *What is the reason for the lack of communication between scientists in the Soviet Union?*

A. They don't trust one another.

Q. *Don't they have professional societies that meet and hear papers, etc.?*

A. Yes. But ever since the revolution and the seizure of power by the Communist party, these have been founded or taken over by the Government. Only in very recent months have scientists shown some signs of running these societies the way they want, and not the way the ministry of culture wants them to do it.

Q. *Can you comment on the number of scientists and engineers being graduated by the Soviet Union?*

A. Yes. Quite often the number of scientific and technical graduates of all sorts, as published by the Soviet government and alarming us, is misleading. They give diplomas at lower levels of technical competence where we don't. One elementary example: Here in our country, any farm boy can run a tractor. The Russians send them to special schools. This means special diplomas. Quite possibly some such categories are included in the rolls of scientific talent which we see. Also, in our society, though a number of graduating engineers go into selling or other administrative work, the large percentage really work at their trade. In the USSR you will find a much greater percentage employed as administrators. And generally no matter what field you take, you will find the administrative personnel far exceeding similar U.S. operations.

Q. *Have you seen any signs that the Soviet Union is dissatisfied with the number and quality of scientists and engineers it is graduating?*

A. Yes, a Moscow newspaper article on Oct. 4, 1956 quotes V. Stoletov as saying too few are graduated in biophysics, electronics and in the field of computor design and operation. Too many, Stoletov says are graduated in the humanities; also too many degrees are granted for "nothing of theoretical or practical value."

Q. *Have you noted any influence from the German or other European scientists who have been assimilated into the Soviet Union since the end of World War II?*

A. I think the German contribution to Soviet science has been exaggerated in the Western press, particularly here where Americans just won't give the Russians any credit for their originality. Let's put it this way: The Germans have not been the decisive element in Russian successes in recent years. The Russians do have a tradition of science regardless of any borrowing from the West. Look at Dmitri Mendeleyev (Periodic Table); look at Prof. Peter Kapitza, famous physicist and now Nicholas Semyonov, recent Nobel Prize winner in chemistry. Of course, they did profit from Klaus Fuchs, Bruno Pontecorvo and other such traitors. Pontecorvo may have played a more important role than is generally recognized.

Q. *Now, just going to basic Soviet psychology, the nuclear blackmail that's been going on such as the threats to use missiles against Europe and the Middle East—Are they inclined to bluff? Would they threaten the possible use of rockets if they didn't have the rockets to fire?*

A. They would have the rockets. They know the rocket principle; they use rockets in other fields.

Q. *Do you have any idea of how successful they've been in perfecting guidance?*

A. Answering indirectly, I remember in 1945 after we had dropped our Nagasaki and Hiroshima atomic bombs, one American engineer said to me: "We don't have to fear any Russian atomic bomb because they don't have the precision techniques to make a bomb. Tolerances are practically unknown to them." Yet look. They've got it. They got the proximity fuse when we least expected.

Q. *What can you say about their better ability in theoretical work compared to experimental work?*

A. This goes with their interest in paper work and paper calculations. A typical desire of Russian middle and upper class people is not to sully their hands. If you are middle or upper class, why you wear your nice collar, and your hands are clean. The "do-it-yourself" movement just has not come to Russia among these classes. Our tendency to do it yourself is a tremendous source of our technical personnel. There, we overwhelm the Russians. They use basements to shoot people in, not for workshops.

Reports of Red Education Lead False; More U.S. Than U.S.S.R. Postgraduates

Q. *Mr. Korol, I understand that you are preparing for the Center for International Studies at the Massachusetts Institute of Technology a report on Soviet education. What is it and when will it be published?*

A. The Center has recently completed a two-year study of the Soviet educational system. A book tentatively entitled *Soviet Education in Science and Technology* is scheduled for publication in the fall of 1957.

Q. *How many engineering colleges or universities are there in the Soviet Union?*

A. In the Soviet Union a sharp distinction exists between universities and engineering institutes. Universities train scientists; engineering institutes train engineers exclusively. There are thirty-four universities and approximately 200 engineering institutes. Of the latter, about 24, the polytechnic and industrial institutes, offer training in several branches of engineering; the rest are narrowly

specialized for training in a particular field of engineering and, as a rule, for a particular industry. There are, for example, thirteen institutes for training engineers in "Mechanization and Electrification of Agriculture."

Q. *Much of a sensational nature has been printed in the American press on the quantitative dimensions of Soviet education. What are the real facts? Do they train more people than we do?*

A. The Center's study has been less concerned with quantity than with the qualitative aspect of Soviet training.

Both relative to the population and in absolute figures Soviet enrollment in schools of higher education is well below that in the U.S. For instance, in 1955-1956 American college enrollment was nearly three million and in the U.S.S.R. somewhat less than 1,900,000 including 640,000 part-time, extension students. What is important, however, is that in the U.S. most college students take liberal arts whereas in the U.S.S.R., the reverse is true. Thus in some professions, including engineering, the rate of training in the Soviet Union now for several years has been higher than in the United States.

Q. *What about graduate training? I remember reading that the output of graduate students is about twice as large in Russia as in the U.S.*

A. That is not so. In 1955, for example, the number of Ph.D. degrees earned in the U.S. was 8,840, including approximately 4,400 in science. This compares with some 7,700 Soviet graduate degrees most nearly corresponding to the American Ph.D. (*kandidat* of sciences) awarded in the U.S.S.R. in that year. This is like comparing apples and oranges. The Soviet figure includes *kandidat* degrees not only in science but in all fields of training—including education, arts, economics, Marxism-Leninism, etc.

Q. *Is a Soviet trained physicist, chemist, or engineer as well qualified as his counterpart in the U.S.?*

A. In general, comparing scientific training, there are no significant differences between, let us say, an American Ph.D. in physics and his Soviet counterpart. The difference increases, however, as we go down the academic ladder. At the high school level the science and mathematics content of instruction in the Soviet Union is, statistically speaking, very much greater than it is in the U.S.

Q. *What do you mean by "statistically speaking?"*

A. All Soviet "high school" pupils take one and the same course. He is heavily oriented toward science and mathematics. Thus *every* Soviet "high school" graduate—1.3 million of them in 1955—has had the equivalent of more than four years of high school mathematics (through trigonometry) and nearly six years of high school science.

Q. *How many of the "high school" graduates in 1955 went on to higher education? How were they selected —by aptitude tests, scholastic record?*

A. No more than 220,000 of these new graduates were admitted to the institutions of higher education—perhaps considerably fewer. The present admissions policy is to give preference to older "high school" graduates, those with two or three years of work experience.

A Soviet applicant may apply to only one school in any year. Selection is made on the basis of competitive examinations in several subjects, taken orally and graded subjectively by individual examiners. I do not think this system provides the best means for selecting the most able and promising students.

Q. *What happens to those who don't pass?*

A. In practice they may not get another chance to apply for resident study. Going to work is the obvious alternative. They may then enroll in an extension course of higher education. Another alternative is to qualify for admission to a "technicum," a school for sub-professional training in various fields. Engineering and industrial technicums, with their two-year courses of sub-professional training following graduation from "high school," are similar to U.S. institutes which train engineering technicians. Here is one area of training that the Soviets have been strongly promoting. We estimate that by 1958 they may train at the rate of approximately 140,000 engineering and industrial technicum graduates per year. In comparison the present output of engineering technicians in the U.S. is perhaps not more than 20,000 per year.

Soviet Science Academy Voted Into IAF But Must Still Supply List of Members

Q. *Mr. Haley, what has been your association with Soviet scientists?*

A. My first acquaintance with them was at the Copenhagen Congress of the International Astronautical Federation in 1955. Two Russian gentlemen came in an official capacity, namely Professor Ogorodnikov of Leningrad and Professor Sedov. They listened quietly to the Congress proceedings. Then they agreed to a press conference at the Soviet Embassy which I attended. I can't recreate the acute and searching questioning by reporters but my impression was that the answers were adroit and uninformative. I always have been acutely aware of the problem of re-entry to the earth's surface—of an object, flying in outer space; so, rightly or wrongly, I asked Professor Sedov myself if Russian scientists have studied the problem of re-entry of earth circling satellites back to the earth's surface. He seemed a bit perplexed. So did Ogorodnikov. Their answer was that this sort of question was not on the agenda. Socially, the two professors circulated freely among all people. Nothing was said, that I heard anyway, that had any ideological bearing on the problems of rockets.

They showed no knowledge of rocket techniques either theoretical or in the field of hardware. On the other hand they showed no lack of knowledge. All they showed was that they were not going to give any information. Then at the IAF Congress in Rome last year, I actively sponsored the membership of the Moscow Academy of Science in the IAF. Prof. Sedov was elected vice president. The purpose of the IAF is essentially civilian and peaceful, and in order to be able to have civilian and peaceful earth circling satellites, we need the common consent of all the nations of the world. Certainly we need the consent of a nation which controls one-sixth of the land surface of the world. Therefore, I though it was my duty to insist that the application of the USSR be acted upon favorably by the IAF so that they not only shared the benefits but also the duties and responsibilities.

There were a few remissions in the information they submitted, however. They didn't have a copy of the constitution of their committee. So we want that. Another was that they didn't have a full list of the membership, which we want, and we'll never get such a list if they don't have an official standing in our organization. ★

B. Ellis (center), head of the Propulsion Department, discusses methods of accurate thrust termination for a ballistic rocket with Dr. Howard M. Kindsvater (left), propulsion staff engineer, and André P. Bignon, propulsion research specialist.

PROPULSION ACCURACY—*a major missile problem*

Controlling power action is but one of the major problems facing propulsion engineers and scientists. Important advances in this and related areas of propulsion are necessary to missile systems now in development.

Because of the growing complexity of problems now being approached, Propulsion Engineers find their field offers virtually limitless scope for accomplishment. The ability to perform frontier work is essential.

Engineers and scientists possessing a high order of ability and experience in propulsion and related fields will be interested in new positions now at Lockheed Missile Systems Division's Sunnyvale and Van Nuys Engineering Centers. Inquiries are invited.

One Electric Power Absorber Now Replaces 27 (500 W) Stick Resistors

Saves 2500% on space. Saves 666% on weight.

The SUN ELECTRIC Power Absorber is designed for continuous duty up to 15 KW. The single unit, which replaces a whole bank of old-fashioned stick resistors, is light in weight and small in size.

Why the SUN ELECTRIC Power Absorber can save you money in your generator test operations:

- Weight—only 1 lb. per KW
- Rugged and shock-resistant
- Nichrome V-ribbon resistor offers maximum cooling surface
- Occupies only ½ cu. ft. space
- Fully protected against overload
- Motor self-cooled, can be made part of load or operated by an external source of power
- Cadmium-plated dichromate finish meets military specifications

What the Russians Tell . . . and What They Don't Tell

By Albert Parry
Professor of Russian Civilization and Language, Chairman of the Department of Russian Studies, Colgate University, Hamilton, N. Y.

Exactly one year ago, in February 1956, at the Twentieth Congress of the Communist party in Moscow, the Soviet Defense Minister Marshal Georgi K. Zhukov declared that Russia already possessed "diverse atomic and hydrogen weapons, powerful rocket and jet armament of various kinds, including long-range rockets."

Two months later, on April 23, during his (and Bulganin's) state visit to England, Nikita S. Khrushchev, first secretary of the USSR's Communist party, boasted even more boldly of Red progress in guided missile development. Soon, he said in his speech to the Birmingham Chamber of Commerce, the Soviet Union would have a missile armed with a hydrogen bomb warhead able to hit any spot in the world—meaning, of course, any spot in America first of all.

How soon?

Apparently not yet by the end of 1956. But other, nearer Western countries could by then be reached. "If rocket weapons had been used against Britain and France . . ." warned Premier Nicholas A. Bulganin ominously in his message to Prime Minister Anthony Eden of Britain and Premier Guy Mollet of France on November 5 in connection with the Suez crisis. He threatened to use against England and France, not the Soviet "naval or air forces," but "rocket equipment."

This, by Moscow's official announcement, meant that already three months ago the Soviet Union had means of rocket attack spanning whole nations—if not entire oceans and great continents as yet.

But beyond these statements, threatening or triumphant though they may seem, neither the Soviet people nor the outside world is told by the Moscow leaders precisely what has been achieved in Russian warhead-rocket research and production—exactly how far the guided-missile experimentation of the military type has progressed in the Soviet domains.

Our side tries, naturally enough, to "guestimate" the very latest state of Soviet accomplishments in this crucial field. But the Soviet leaders are no fools. They do not rise to the bait. They make no statements either to foreigners or in their own Moscow press either denying or confirming our intelligence.

In May 1954 George P. Sutton, chief of the Aerophysics Department of North American Aviation, Inc., stated that according to his information the Soviet Model 103, a liquid-propelled rocket engine, weighed very little, yet had the thrust of 53 conventional turbojet engines or more than five times the thrust of the German V-2 rocket. The Red goal, he said, was to evolve a 5,000-mile-per hour guided missile.

Any Soviet reaction to this American revelation? None whatever. Hard as we searched the Moscow press for any comment on Mr. Sutton's statement, there was nary a word.

Symington Reveals Red ICBM

On July 21, 1954, Senator Stuart Symington of Missouri, former Secretary of the Air Force, spoke of the Soviet attempt to produce an intercontinental missile with a hydrogen warhead of 4,000 to 5,000 mile range. Did Moscow acknowledge this declaration with any further clarification of its own? Not at all.

That the Soviet Russians had built long-range guided-missile launching platforms "at dozens of points in Europe and Asia . . . in a pattern allowing an arc of fire to cover, for instance, the Baltic Sea," was disclosed on May 18, 1955, by Representative Overton Brooks, a member of the House Armed Services Committee. Barely a month later, in mid-June 1955, our own Erik Bergaust reported after a trip to Europe that the Soviets had a liquid fuel rocket engine capable of developing a quarter-million pounds' thrust and a missile arsenal "as advanced as it is substantial." But again Moscow's response was, in effect, "No comment."

On February 5, 1956, Senator Symington returned to the theme by pointing out that the Soviet Union had tested an intercontinental ballistic missile which went "hundreds of miles further" than any such weapon then tested by the United States. The Russians, he added, were "well ahead of us." Insisted the Senator:

"I don't 'believe' the Soviets are ahead of us in ballistic missiles. I *state* that they are ahead of us in ballistic missiles."

Any significant echo from Moscow? Mum was still the Red word.

Similarly there was neither "yes" nor "no" from the Reds to other American statements that, late in 1955, the Soviets had missiles with ranges up to 1,500 miles; that by late 1956 these ranges surely increased; that Soviet submarines could fire ballistic missiles over distances of 650 miles when submerged and nearly 1,500 miles on surfacing.

But if not all such things, then just what are the Soviets saying about their rocket research and experimentation?

Mostly they tell their people of *our* guided-missile work and in the process call us nasty names because, the Moscow propagandists repeat again and again, in our rocket experimenta-

tion we mean war only, never peace—and aggressive war, at that, not merely defense.

On March 3, 1956, *Sovetsky Flot* (Soviet Navy), the official Russian navy organ, denounced the latest American development of guided missiles as being "for offensive purposes" and "aggressive plans." The Russian article carried as its illustrations detailed sketches of three American missiles (*Terrier, Regulus,* and *Petrel*) along with data as to their range, speed, weight, warheads, and guidance systems, also the types and names of United States warships being re-equipped for missile operations. Significantly the Soviet navy journal remarked that, of course, such "weapons can be used by both sides"; in other words, that the Soviet Union had such missiles, too.

Lists US Peace Rockets

It is true that the article on *Raketa* (Rocket), in Volume 35 of the Great Soviet Encyclopedia (July 1956), lists two peaceful American missiles along with three military ones, but the general tone of Soviet writers is "Be on guard against that warmongering America, fellow citizens!"

"We must not forget," warns Boris V. Liapunov, a Soviet engineer specializing in writing about missiles and rockets for the layman, "that guided missiles can carry not only scientific-research equipment, but also explosives; not only mice and monkeys, but also atomic warheads." He makes this statement in his article *"Samoliot-Raketa-Snariad"* (Plane-Rocket-Missile) published in the Moscow *Ogoniok* (Little Fire) on May 1, 1955. He does not say anything clear or definite about the Soviet investment and accomplishments in guided missiles. Instead he cautions the Russian reader that "the aggressive circles of the imperialist countries devote considerable attention to guided missiles as a weapon of mass destruction."

In such countries (meaning the United States first and foremost), "guided missiles of most varied types are being planned and tried out for the army, the navy, and the air force." What can or will or do the Soviets undertake to counter this danger from the West? Plenty, hints Liapunov. "Like atomic weapons or any other weapons, pilotless arms have two edges. Rockets and pilotless missiles are in themselves a target for our means of defense."

But will the Soviets attack first? Comrade Liapunov hedges on this a bit: "Soviet people demand prohibition of the weapons designed for the mass annihilation of humans. Science should serve peace and prosperity of mankind. With their pilotless aviation Soviet people will conquer the ocean of air, will study the world's space." His implication is that this Russian conquest will be wholly peaceful, but should any foreign power stand in its way—look out!

Earlier, in 1954, and speaking this time directly to Soviet soldiers, the very same Boris V. Liapunov charged "the imperialists" with the evil intention of "using rocket technology to wipe out people en masse." He issued this warning toward the end of his book *Raketa* (Rocket) published in Moscow in the series "Scientific-Popular Library for Soldiers and Sailors" by the Soviet Defense Ministry. "Modern technology," he wrote, "permits the utilization of rocket weapons over distances of thousands of kilometers, without employing airplanes." But, continued Liapunov, the Soviet armed forces have such weapons, too—strictly for defense purposes, "to give a smashing repulse to the foe in case he dares to aggress." We, the Soviets, also have "scientists, engineers, designers, and industrial specialists" in this newest field!

Explaining to the Soviet soldier and sailor the scientific principle of Soviet "defensive" guided missiles, Professor Kosmodemiansky closes his recent book with this eloquent appeal:

"Warriors of the Soviet army, navy, and air force! Remember that these days science stands beside you in defending the frontiers of the Socialist Power. Think as you create and improve your fighting technology. Daydream, indulge in fantasies; then check your daydreams and fantasies by mathematical calculations and practical experiments. Always bear in mind the proud motto of Constantin Eduardovich Tsiolkovsky: *That which is impossible today will become possible tomorrow!"*

In many such Soviet books and articles the "glorious" tradition of the use of rocket weapons by the Russian armed forces is continually stressed.

Soviet Guided Missile Czar—
Air Marshal Zhigarev

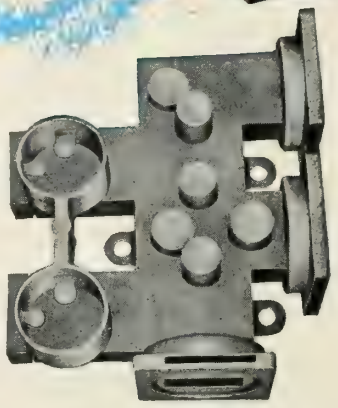
By text and picture it is recalled that Russian military commanders and engineers first introduced rocket artillery in their wars of the early 19th century; that Russian inventors constantly perfected such weapons; and that under the Soviets, in World War II, the celebrated "Little Kitty" (*Katiush*) or modern rocket artillery truly distinguished itself.

In their discussions of rockets and missiles of other than military nature, Soviet writers like to dwell again and again on the pioneering work of Tsiolkovsky and other Russian professors of the first 30 years of this century. They also boost the "boomerang-to-the-Moon" project of our contemporary Professor G. Chebotarev. They revel in detailed descriptions of the artificial satellite of the Earth soon to be launched by the Soviets; also in the blueprints of Soviet mail-service by rocket, and in other such peaceful accomplishments or plans.

In their book *Samoliot-Raketa* (Rocket Plane) published in Moscow in 1953, L. K. Bayev and I. A. Merkulov praise not alone Tsiolkovsky but also such pioneers as F. A. Tsander and Yu V. Kondratiuk. These Russian researcher-inventors are lauded in the little volume for their suggestion "to utilize as fuel for rocket engines such metals as magnesium and aluminum . . . by burning them in oxygen or by combining these metals with the chemical element of fluorine, this leading to a great yield of heat energy." The authors point out that "this enhances the energy of the fuel and, besides, allows to burn, toward the flight's end, those parts of the flying apparatus which by then would become unnecessary anyway." Soviet readers are informed that here lies the solution of the problem of how to increase sharply the range of flight.

No Manned Satellites

Lucid explanations of Professor Chebotarev's project of sending a rocket to the Moon and back have been appearing in the Soviet press quite frequently, the best of these having been presented in *Literaturnaya Gazeta* (Literary Gazette) of October 20, 1956, and *Trud* (Labor) of September 30.



In effect cautioning the Soviet reader against too much optimism, G. B. Kozhevnikov (an engineer) wrote in his treatment of radioelectronics and the artificial satellite in *Radiotekhnika i Elektronika i Ikh Tekhnicheskoye Primeneniye* (Radiotechnology and Electronics and Their Technical Application, Academy of Sciences, Moscow, 1956) that it was far too premature to expect the actual manning of the satellite with human beings. "Mod-

Radar components and other electronic parts must be produced to rigid design specifications and to meet high inspection standards, since part failure may often endanger the lives of the men depending on it for their survival.

ARWOOD Investment Castings simplify design responsibilities, insure dimensional accuracy of complex cored passages and reduce material costs. Reduced weight, greater strength, improved appearance, lower production costs . . . benefits for you when you specify INVESTMENT CASTING!

ARWOOD application engineers are available, without obligation, for consultation in your design and production planning. Contact us when you reach the "blueprint stage" to take advantage of INVESTMENT ECONOMIES.

CASE IN POINT!

Improved performance and reduced production cost, resulted from investment casting this radar mixer body. Previously fabricated from 20 machined components by brazing, waveguide performance was unsatisfactory due to inaccuracy of dimensions and differentials in electrical characteristics. Now made as an integral investment casting, the parts are within dimensional tolerances, the electrical characteristics are uniform, and the cost is 75% less!

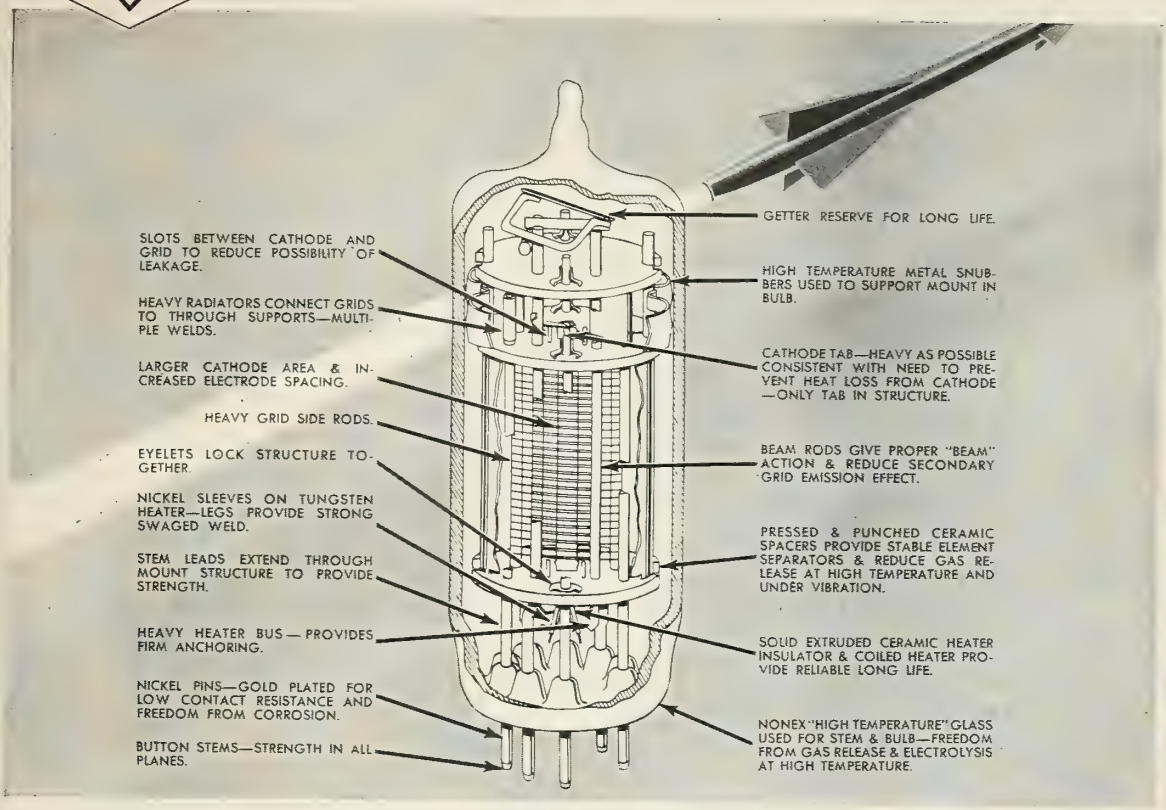
ern rocket means now available," he remarked, "do not yet permit us to launch a satellite large enough to lift into space one or more men."

On the other hand, Yu. Khlebtsevich (a candidate of technical sciences) showed considerable confidence in the prospects of rocket work in Russia when in his article on the artifical satellite, published in *Literaturnaya Gazeta* on July 10, 1956, he maintained: "We must note that from the viewpoint of modern technology the launching of an artificial satellite does not present any particular complexity. In the future, satellites will set out on their flights by the score—to various heights, along different orbits."



Speaking of what may prove actually practical in the very near future, Liapunov in his already quoted *Ogoniok* article discourses on Soviet postal-service rockets. He makes a point of insisting that such mail-rockets are "no idle fantasy." The Red project of such mail service, he says, is based on "the entire experience of rocket technology, in cooperation with radiolocation and automatics already creating remarkable pilotless machines flying faster than sound." Postal rockets are planned to connect Moscow with the farthest cities "of the European part of the country." Soviet Asia will evidently have to wait for such boons. No more than one-half hour will be needed to reach, by postal rocket, the farthest European Russian city from the Soviet capital. "The sending of a letter will most likely cost not more but less than it does now, yet think of the tremendous time gain!" exclaims Liapunov. To his text he appends a drawing by N. Grishin, a Soviet artist, showing the landing of a mail-rocket of the future.

In another of his numerous texts —in his 1954 book *Raketa*—Liapunov predicts an equally early use of rockets for shipping freight "from one end of the country to another in a matter of just a few hours." Here Soviet Asia is included—else the time lapse would have surely been stated in minutes.

And in his 1955 volume entitled *Rassakzy o Raketakh* (Tales of Rockets) the same author become eloquent about Soviet peaceful progress to the point where he proclaims that "we have never had and could not have rockets that would serve as means of destroying of a mail-rocket of the future.

Here the Red signals have certainly become crossed. How this peaceful use of warlike rockets could be possible, in view of all the statements by Khrushchev, Bulganin and Zhukov about Soviet possession of warhead-carrying guided missiles, only the main Moscow propaganda office in charge of Liapunov's writings can figure out. ★

HY-G-300 **ELECTRON TUBES FOR SURVIVAL**

WHY BENDIX* HY-G-300 ELECTRON TUBES ARE BEST FOR EXTREME SHOCK, VIBRATION AND TEMPERATURES!

From the standpoint of design features (see above), these reliable hard glass tubes offer the superior quality needed to survive today's severe environmental demands.

Specifically, Bendix HY-G-300's are designed to withstand the following environmental conditions—bulb temperatures up to 300° C; vibration up to 20G's over the range of 5-2000 cycles; and shock of 200G's having 20-millisecond duration.

For full information about the HY-G-300 line . . . the surest answer to electron tube applications in jet aircraft, missiles and rockets . . . write RED BANK DIVISION, BENDIX AVIATION CORPORATION, EATONTOWN, NEW JERSEY. *TRADEMARK

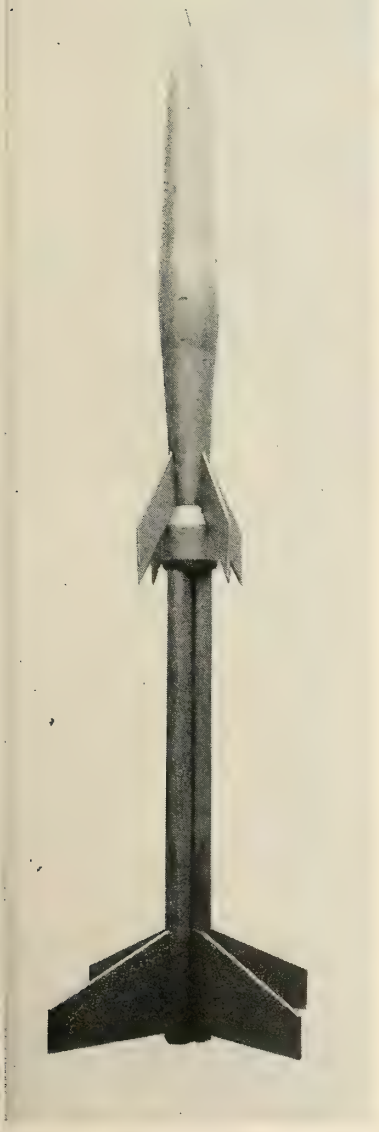
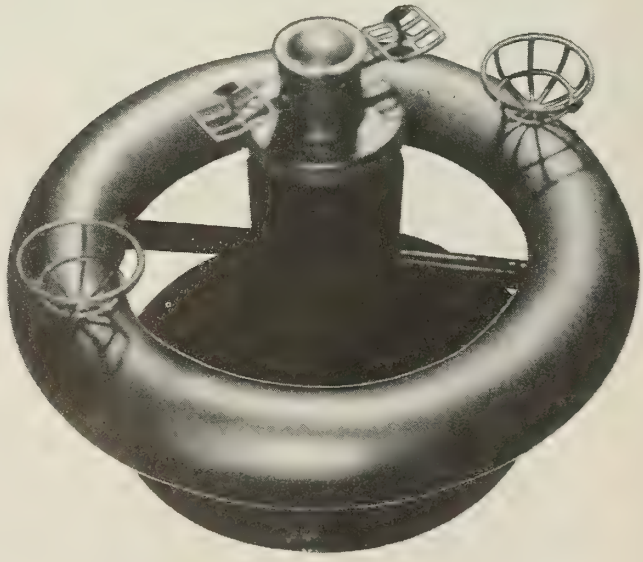
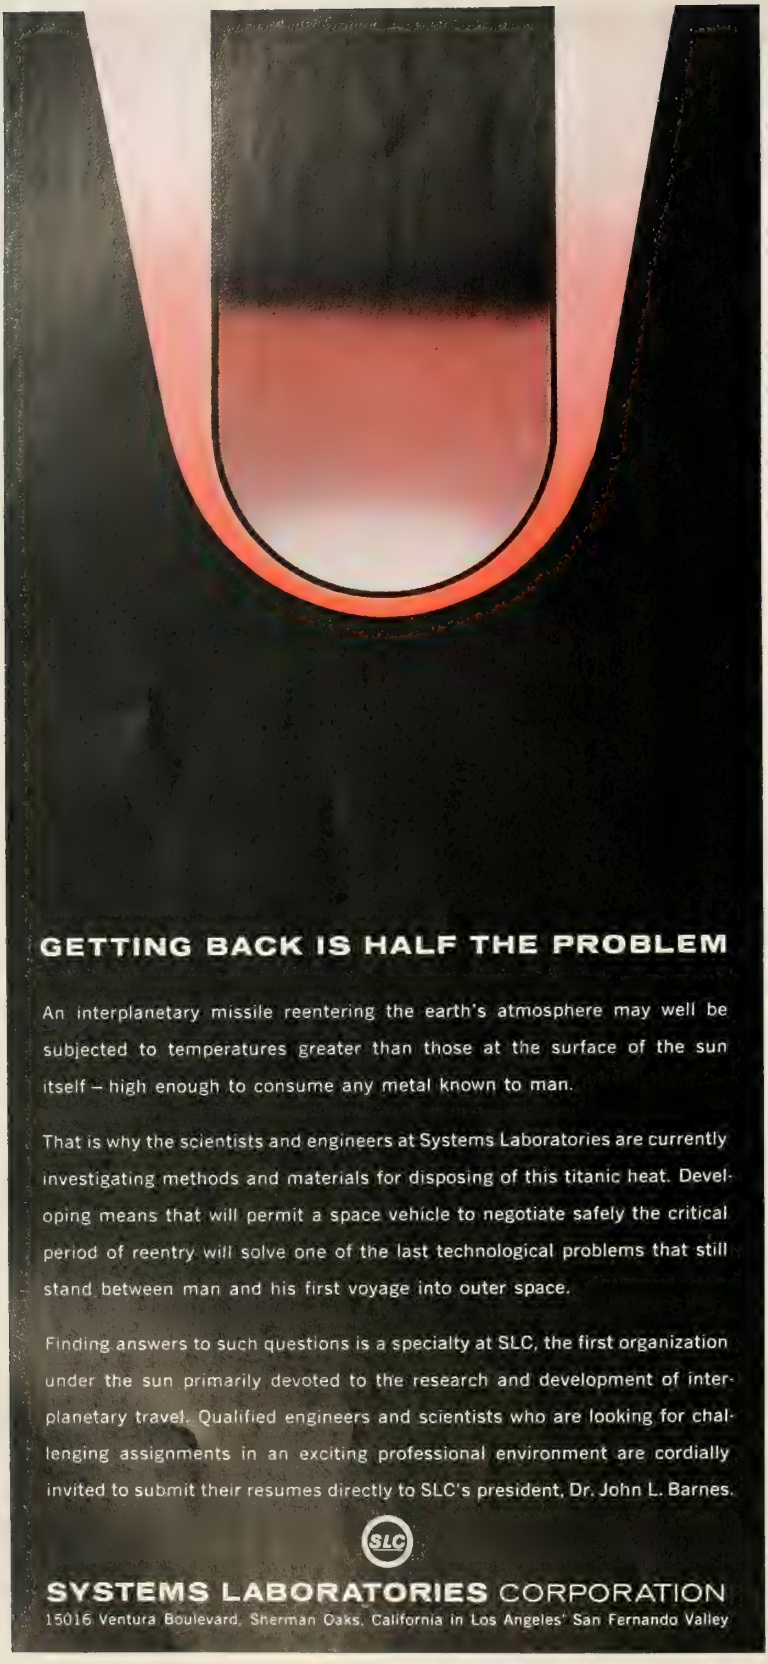
Behind-Iron-Curtain Rocket Show



The Silesian Planetarium and Astronomical Observatory in Katowice in Poland has been the home of a recent rocket and space flight exhibit sponsored by the Polish Astronautics Society in cooperation with the Museum of Technique of the Chief Technical Organization NOT. Several German and Russian items were displayed. Of particular interest was a modified Russian T-7A research rocket (left) which is believed to be of the size and have the performance of our Honest John.

Director of the Silesian Planetarium, Professor Satabun, right, is posing in front of picture of space man with Wladislaw Geisler, physics engineer and president of the Silesian Section of the Polish Astronautics Society. Geisler was a delegate to last year's International Astronautics Federation Congress in Rome, Italy.





Satabun and Geisler looking over V-2 components. Main pump and turbine unit (left), and gas generator are displayed. Undamaged, well-maintained equipment and components were contributed by the Russian Army. They were shipped from Soviet missile schools. Numerous research rockets also were provided by Reds.

Russian Mach 4 sounding rocket. Notice crude first-stage booster and fixed stabilizer fins. Booster consists of four solid-propellant chambers believed to be modified aircraft rockets. Odd-size second stage contains instrumentation and small parachute. Reports say Russian research rocketry is extensive. Large rockets have carried animals to 300 miles, Reds say.

Model of Russian space station, similar to Wernher von Braun's famous "pinwheel." Interest in astronautics is overwhelming, according to Geisler. He told m/r the exhibit has been visited by more than 20,000 in less than four weeks. Exhibit is now touring Poland and might also go to other satellite countries.

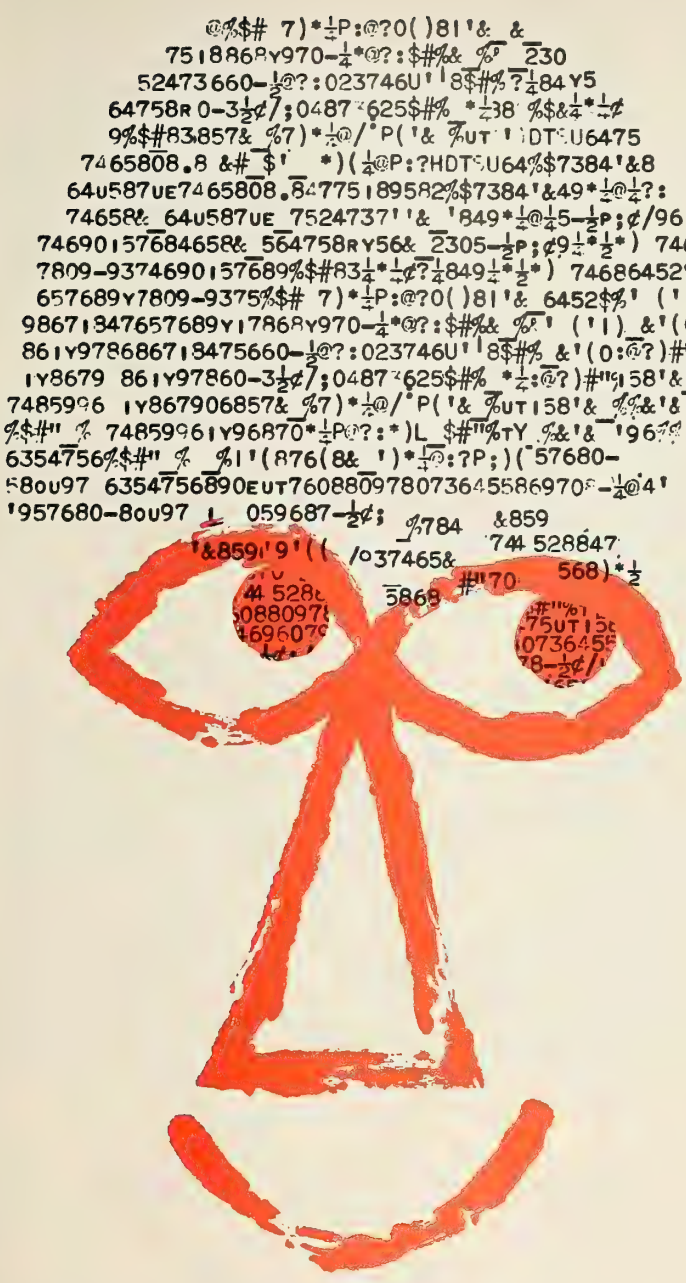
international briefs

USSR Aviation Minister Honored

P. V. Dementyev, minister of the aviation industry in the U.S.S.R. has received one of the highest awards of the Presidium of the USSR's Supreme Court. Dementyev received the Order of Lenin on his 50th birthday "for his services in aviation industry development."

Supersonic Atom Plane Design Shown by British Firm

The British company, Hawker-Siddeley Nuclear Power Co. has published general details of its version of a supersonic nuclear powered aircraft in the Hawker Siddeley Review, a company house organ. Though, the general design is too heavy for missile application, it is a first step in the direction of a nuclear rocket. Noting that low weight and space are essential, the article says:



"At present a fast reactor with highly efficient liquid-metal heat extraction would seem the most suitable system, although there are strong arguments in favor of a gas-cooled system even at the expense of some increase in size. The crux of the aircraft problem is a successful evolution of the concept of partial shielding but, even so, such aircraft will be large with all-up weights probably greater than 100,000 pounds."

The Hawker-Siddeley configuration shows two wing-tip turbines driven by a reactor situated about amidships in the fuselage.

Britain Schedules Testing Of Skylark Rocket

Test firings of Great Britain's upper atmosphere research rocket is scheduled soon at Woomera. The *Skylark* is 25 ft. long, 17½ in. diameter and is stabilized by three swept fins. It is powered by a Bristol Aircraft Raven dry rocket, which has a maximum thrust of 11,500 lbs. for a nominal 30-sec. period.

The initial design ceiling is 70 miles with 120 miles foreseen for later variants. The launching tower at Woomera will be 80 ft. high and once a predictable trajectory has been proved, firings will continue from a similar tower at the MoS missile center of Aberporth, Wales.

do you have a head for figures?

. . . and do they bound from your cranium with a purpose? Then you're the Mechanical Engineer we're looking for at Firestone—a man with real scope who wants to work in a creative climate.

At Firestone, minds like yours have provided leadership in research, development and manufacture for 57 years. Currently, you'll help carry forward the vital development program for the Army's "Corporal." Perhaps more exciting, our facilities in both Los Angeles and Monterey are blazing new trails that should lead to satisfying, history-making goals.

Right now, we need more ME's, who can head their figures in these directions:

Stress Analysis
Mechanical Test Engineering
Machinery Development
Materials & Process
Structures

We have a man at Firestone who can figure on a happy future for you. Write him. He'll arrange a meeting.

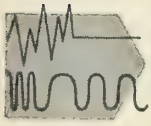
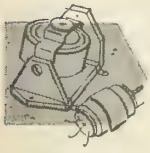
DC to DC and DC to AC solid-state power converters voltage regulated, frequency controlled, for missiles, telemetering, gyros, servos



Interelectronics Interverter solid-state thyratron-like elements and magnetic components convert DC to any number of voltage regulated or controlled frequency AC or filtered DC outputs from 1 to 1800 watts. Light weight, compact, 90% or better conversion efficiency.



Ultra-reliable in operation, no moving parts, unharmed by shorting output or reversing input polarity. Complies with MIL specs for shock, acceleration, vibration, temperature, RF noise.

Now in use in major missiles, powering telemetering transmitters, radar beacons, electronic equipment. Single and polyphase AC output units now power airborne and marine missile gyros, synchros, servos, magnetic amplifiers.

Interelectronics — first and most experienced in the DC input solid-state power supply field, produces its own solid-state gating elements, all magnetic components, has the most complete facilities and know-how—has designed and delivered more working KVA than any other firm!

For complete engineering data write Interelectronics today, or call LUdlow 4-6200 in N. Y.

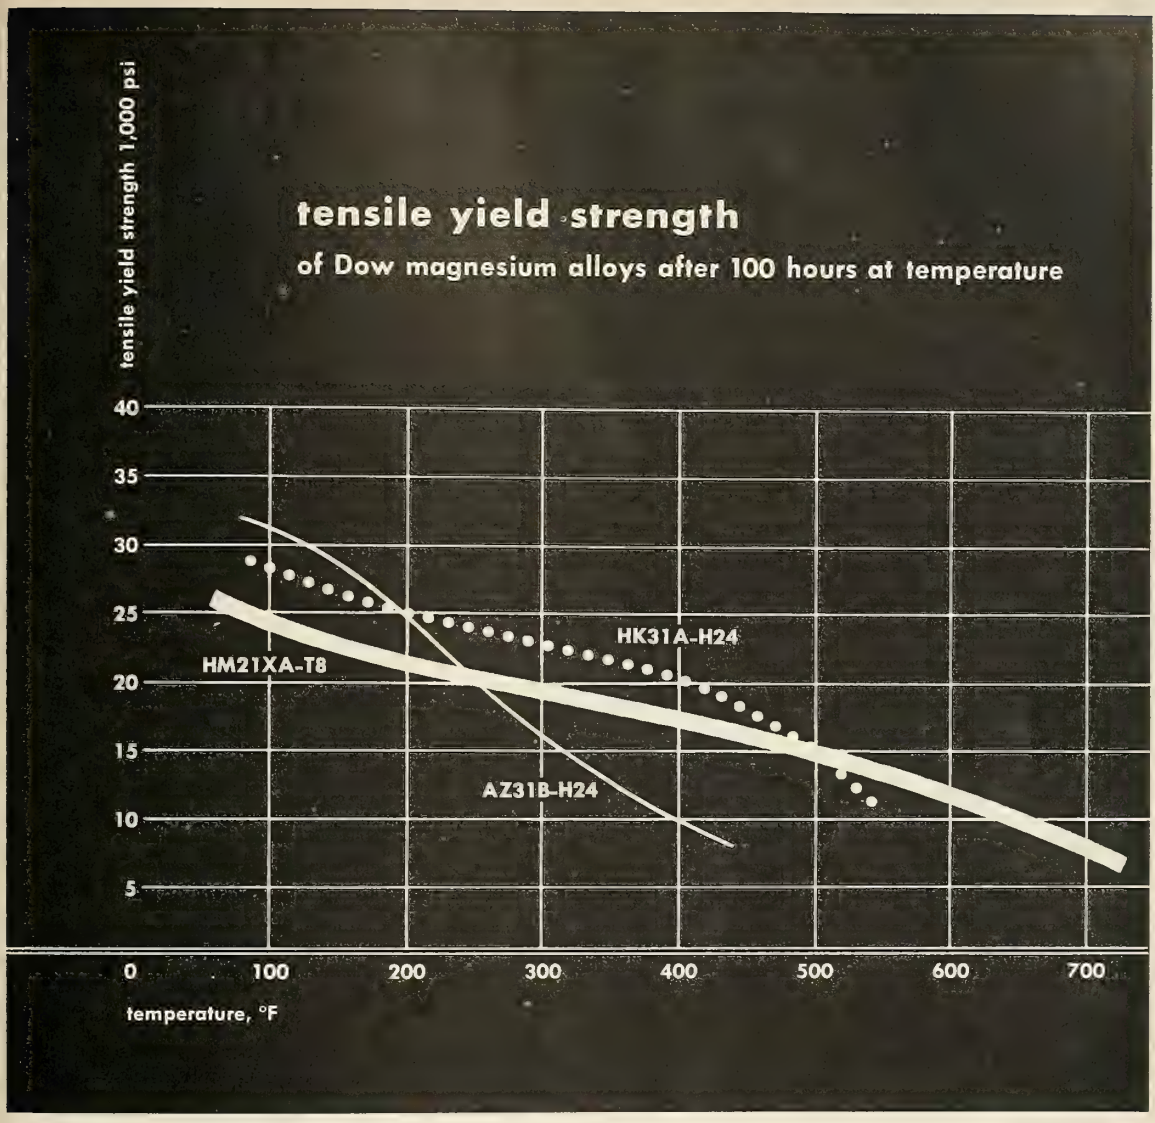
International Scene



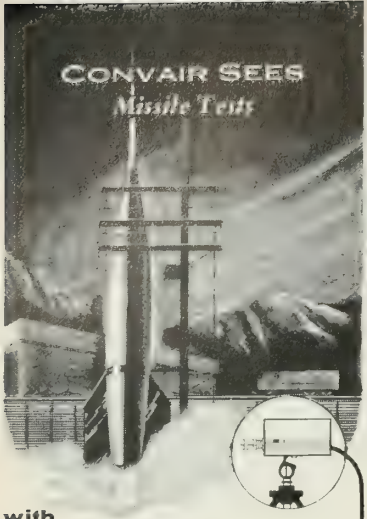
By Anthony Vandyk

None of the group of reporters, including this writer, who visited Russia last year saw any trace of Soviet missile activities. It was some consolation to learn that General Twining did no better. "We met a blank wall," he said. Nonetheless, Soviet aircraft production methods can give a clue to missile production techniques. Three things about Soviet aircraft production methods impressed the Twining group. First, the assembly jigs were light and simple; in contrast with the American practice of employing forgings or extrusions, welded sections were used for landing gear and similar structures. Second, curved sections were fabricated from sheet aluminum on simple hand-operated light hammers, while more difficult sections were formed by air-activated, hydraulic stretch processes managed by simple hand control. Third, the wing and fuselage sections in the plant visited by the Twining group were built up by the riveting together of smaller parts.

The two plants to which the Twining group was permitted were among the oldest in the Soviet aircraft industry and are not representative of the modern production facilities that exist elsewhere in Russia. Nonetheless, says Twining, there is good reason to believe, even on the basis of these two examples, that the Soviet Union possesses "in high degree the ability to apply mass production processes and techniques to the manufacture of airframes and jet engines." In research facilities the Russians seemed to Twining to be doing well. At the Zhukovski Air Engineering Academy the Twining group was given a demonstration of a Mach 3 wind tunnel. The aircraft model used was a true delta design. From the shock waves produced when it was subjected to the ultrasonic air stream, "it was clear that this tunnel was a bona fide Mach 3 testing device," Twining reports. There was another wind tunnel at the academy which the Russians said should produce Mach 5 conditions but this was not put into operation for the American group.

During a visit to the Air Force Academy at Monino the Twining group noticed several models of U.S. aircraft in a classroom devoted to the study of fighter tactics. Among the models represented were the B-52, F-100, F-101 and the B-66—but no missiles. This writer saw photographs of the Matador and the Regulus in the Air Museum in Moscow but there was no material whatsoever on Russian missiles. During the fairly extensive travels of the group of reporters accompanying General Twining no missiles or apparent launching sites were observed. The reporters were allowed to travel freely in the Moscow area and many numerous flights on commercial aircraft to and from the Soviet capital. It is probably that the aircraft use air corridors that avoid areas of special military interest. Nonetheless, it is amazing that not a single missile or launching sight has ever been detected by a Western reporter, particularly since many reporters and other observers have seen Russian radar installations.

The Russians' missile potential is of vital interest to the Western world at a time when Britain is planning to cut its defense expenditure and concentrate most defense production on a long-term missile program which is unlikely to show any results before the end of this decade. At this writing it seems that the U.S. will have to defend the western world with missiles for several years to come, either directly with missile-equipped units based in foreign nations or indirectly by supplying the armed forces of NATO allies with U.S.-built missiles. The possibility of extending the off-shore procurement to the missile field exists but it does not seem to offer a satisfactory solution to the problem of bolstering the overall missile defense of the western world in that many of Europe's present missiles are inferior to their U.S. counterparts.



New magnesium alloy holds properties for 100 hours up to 700°F.

Dow Magnesium HM21XA-T8 alloy extends further the range of conditions under which light metals can be used in aircraft design. Second in the series of sheet alloys designed specifically for elevated temperature applications, it supplements the excellent characteristics of HK31A alloy.

HM21XA-T8 retains its properties at temperature during long periods of time. Even one hundred hours at 700°F. results in relatively little change in tensile yield, creep and elastic modulus.

Magnesium lightness is combined with strength at elevated temperature in HM21XA-T8, offering new ways to save weight or gain increased rigidity in the design of missiles and aircraft. This alloy is supplied in the -T8 temper and can be formed in this temper without the need for further heat treatment after fabricating. Samples of HM21XA-T8 along with detailed information are available. Contact your nearest Dow Sales Office or write to THE DOW CHEMICAL COMPANY, Midland, Michigan, Department MA 1400G.

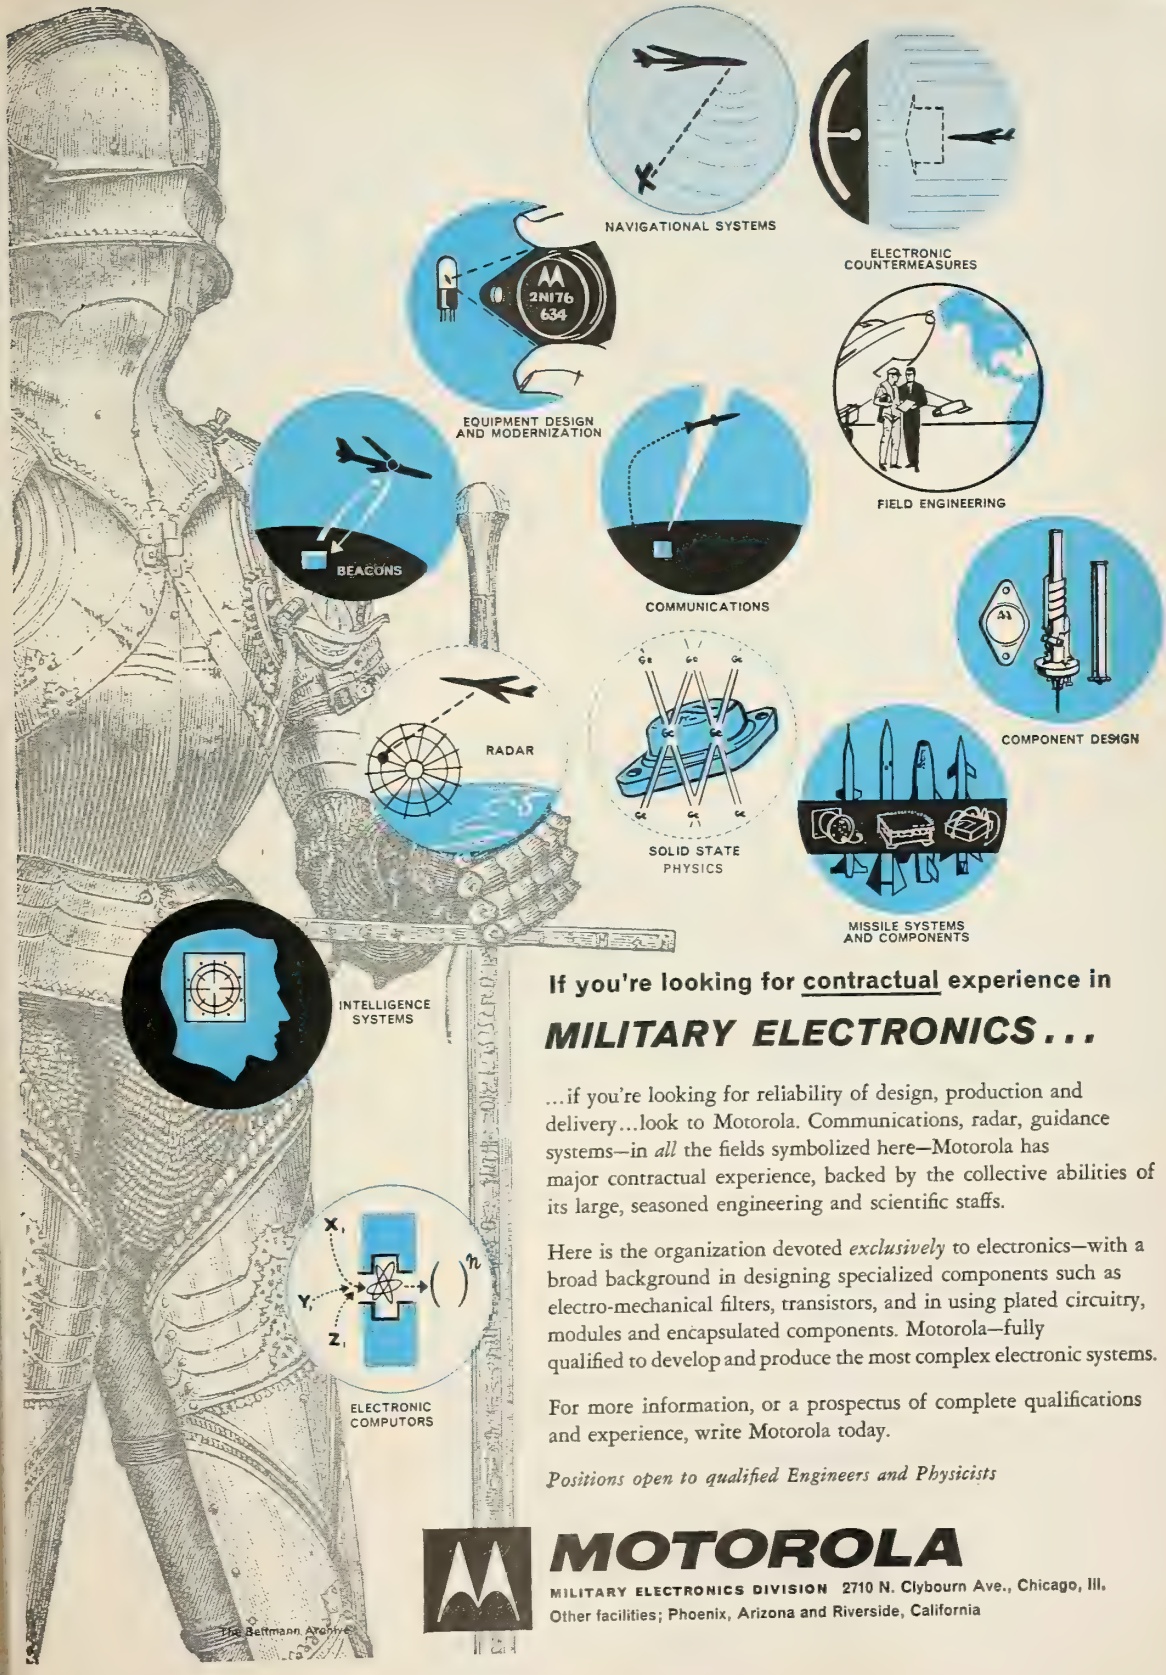
World Astronautics

By Frederick C. Durant III

During the past few years the press has reported the conflicting claims of the U.S. and the U.S.S.R. as to which nation fathered certain major inventions, e.g. the airplane and the electric light bulb. With respect to the science of astronautics, however, there appears to be no argument: Russian K. E. Tsiolkovski was the founder.

It was Konstantin Eduardovitch Tsiolkovski who, in retrospect, most completely realized the relationship between rocket propulsion, mass, and the distances from the earth to other heavenly bodies. Tsiolkovski, a school teacher, published in 1895 his first article on space flight. He was then 38 years old. Until his death 40 years later he dedicated his life to the careful study of the problems he prophetically realized would have to be solved before man could venture into space. Striving for the highest possible specific impulse he sketched in 1903 a rocket ship showing space for liquid oxygen and liquid hydrogen tanks and a sealed, pressurized crew compartment.



In 1929 Tsiolkovski's disciples Fortikov, Rynin and Perleman founded a competent scientific organization for investigating and systematically developing rocket devices. Called the "Group for the Study of Reactive Motion" (GIRD), chapters were formed in Moscow and Leningrad. In 1934 the Soviet Government organized a military rocket research program which paid off in World War II in rocket bombardment weapons, notably the Katyusha. Since the War there has been increasing reference to rockets and space flight in the official press.

The U.S.S.R. was the first major nation to give official scientific recognition to astronautics establishing in 1954 the Tsiolkovski Gold Medal Award for the "best papers by Soviet scientists working in the field of astronautics." A permanent Commission on Astronautics of The Academy of Sciences, Moscow, was announced in 1955. The Academy is the top scientific body of the U.S.S.R. The Commission on Astronautics was the first governmental organization to apply for membership to the International Astronautical Federation which has as members the rocket and space flight societies of twenty other nations.

The Commission on Astronautics is headed by well-known Academician L. I. Sedov and the membership includes the names of outstanding physicists such as Peter L. Kapitsa as well as engineers and astrophysicists. This public and professional recognition of the respectability of astronautics by the U.S.S.R. predated such recognition by the governments of all other major nations.

At the Barcelona meeting of the IGY national committees last September, Professor Bardin, speaking for The Academy of Sciences officially announced the existence of a Russian satellite vehicle project for the IGY and a desire for cooperation in the U.S. satellite program.

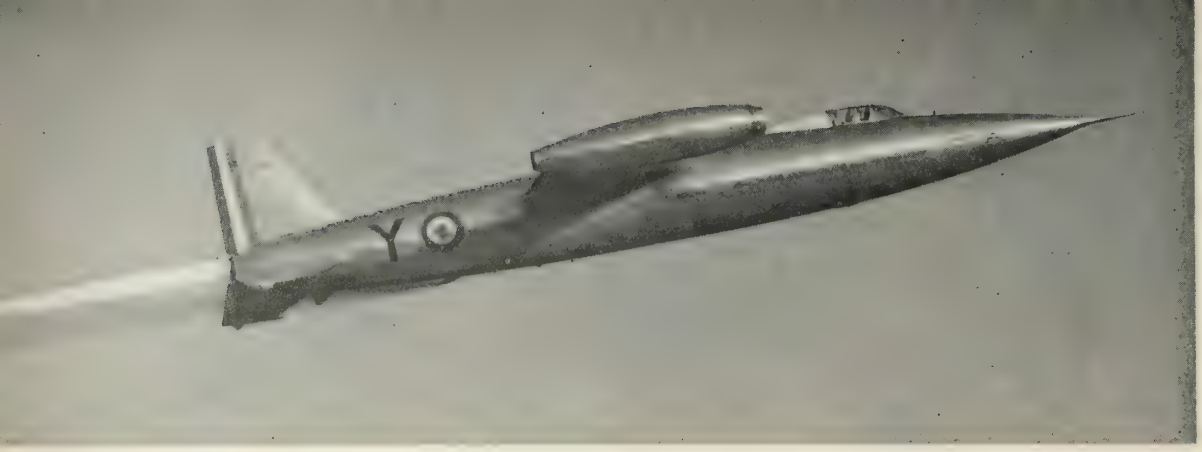
Many rocket engineers fired by the realization that manned space flight could occur in their lifetime even hope for a friendly rivalry and "space race" between the U.S. and the U.S.S.R. Based upon the technology of long range ballistic missiles such research in the upper atmosphere and beyond could result in major breakthroughs in science. Many kinds of data obtainable from rocket research in space can be obtained in no other way. The possibility of military-developed hardware of both countries being eventually used for such peaceful and productive endeavors is an exciting premise.

If you're looking for contractual experience in

MILITARY ELECTRONICS . . .

. . . if you're looking for reliability of design, production and delivery . . . look to Motorola. Communications, radar, guidance systems—in *all* the fields symbolized here—Motorola has major contractual experience, backed by the collective abilities of its large, seasoned engineering and scientific staffs.

Here is the organization devoted *exclusively* to electronics—with a broad background in designing specialized components such as electro-mechanical filters, transistors, and in using plated circuitry, modules and encapsulated components. Motorola—fully qualified to develop and produce the most complex electronic systems.



For more information, or a prospectus of complete qualifications and experience, write Motorola today.

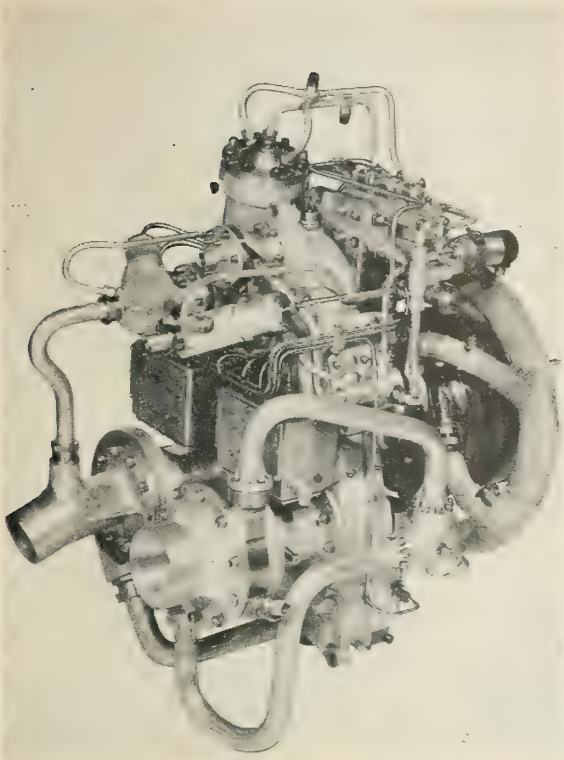
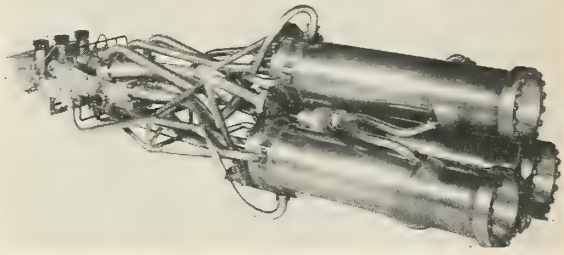
Ouest-Aviation's TRIDENT I is capable of Mach 1.6 at 53,000 ft. Its SEPR rocket motors provide a total thrust of 9,900 lbs. The wing-tip mounted turbojets are used principally for take-off. The rocket units are manufactured by Societe d'Etude pour la Propulsion a Reaction.

French Solid and Liquid Rockets

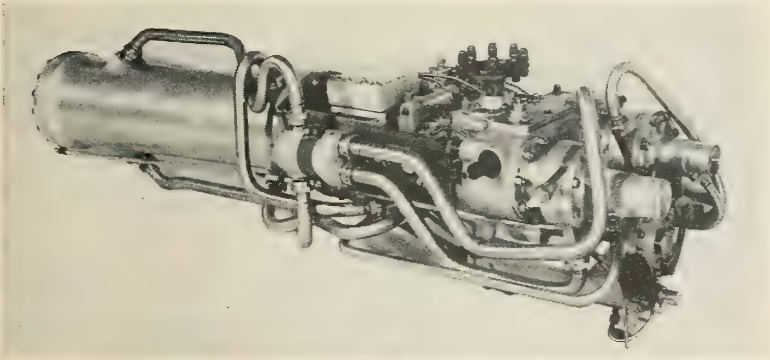


One of the TRIDENT I's three rocket motors is in operation as the aircraft taxies into position for take-off. Overall aircraft configuration is clean, fast.

Tail view of the TRIDENT II shows two rocket chambers. TRIDENT I had three chambers.



The SEPR-73 solid propellant booster rocket develops a thrust of 45,100 lbs. for four seconds. Loaded weight is 1,528 lbs. Combustion chamber pressure is 995 lbs. per sq. in.



This turbopump unit is used in the TRIDENT I's SEPR-481 rocket engine. Unit operates on rocket engine propellants (nitric acid and furaline). Turbine cooling is achieved by separate water supply.

The SEPR-505 solid propellant booster rocket has a thrust of 22,000 lbs. for 4.5 seconds. Weight loaded is 884 lbs. and overall length is 7.9 ft. Chamber pressure is 780 lbs. per sq. in.

This cluster of three SEPR-481 rocket motors is used in the TRIDENT I. Each chamber develops 3,300 lbs. thrust. The 9,900 lbs. total thrust is about 40% greater power than the 6,000-lb. thrust Reaction Motors engine used in the Bell X-1 and the D-588 research planes.

This is one of SEPR's early rocket engines, the SEPR-25 Guepe used for the Ouest Aviation 6025 Espadon experimental aircraft. Developing 3,300 lbs. thrust, the SEPR-25 uses nitric acid and furaline as propellants which are forced into the combustion chamber by a pumping system mechanically driven from the main powerplant of the Espadon, a Rolls-Royce Nene turbojet. Power take-off arbor is located on top (note attachment plate with eight bolts).

Ouest-Aviation's 6025 Espadon was the first French aircraft with rocket power. The SEPR-25 rocket engine of 3,300 lbs. thrust enabled the aircraft to achieve Mach 3 and an altitude of 50,000 ft. Slung under the fuselage is a Rolls-Royce Nene.

Case For Jelly-Propellants

A jellied propellant has the advantage over a liquid since, with proper pumping and feed design, it can be flow-regulated. At the same time, by this regulation of flow mixture-ratio can be changed and throttling rocket chambers can be built. How can a jellied propellant be obtained?

Various organic substances such as the butyl rubbers, various stearates and such gellatinous substances as the saturate amines which have the property of becoming a quasi-solid under the proper conditions of temperature and pressure may be considered. Various metallic additives, such as metallic soaps, have been added to gasoline and have resulted in the jellification of gasoline.

The cresyl and butyl and buna rubbers again have this property and if the rubber producing reaction is not carried to completion but allowed to stop before full polymerization occurs, a jelly rather than a liquid or solid results.

These jellies could be used as fuels but the problem is to produce an oxidizer which is also a jelly. This is much more difficult since ithe chemically active nature of oxidizers is an inherent block to jellification. One approach out of this dilemma is to combine the oxidizer and the jellied fuel in some way without reacting. This seems difficult since the oxidizer naturally wants to react with the jellied fuel.

The way out of this is to put a third additive into the system, i.e. make a three component system and the third additive will then insulate, so to speak, the fuel from the oxidizer, or as the globule of fuel is surrounded by a layer of liquid polyethylene or some saturate fluorinated liquid elastimer, which prevents the oxidization of the fuel. If this mixture is forced into the rocket thrust chamber, and ignition is applied by a spark or igniter, the insulating wall momentarily breaks down and allows the reaction to proceed. Since the jelly is very temperature sensitive and will readily become a liquid, the reaction proceeds in a liquid phase, and goes to completion. Once the proper temperature gradient is established, all the jellied "mono-propellants" continue to react as fast as the fuel can be injected.

The feed systems for jellies, perforce, are more complicated than for liquids since the "fluid" flow friction is so much higher. Many systems using jellies tend to have, therefore, a somewhat more powerful gas generator and thrust chamber machiners to pump an equivalent mass flow of propellant. Special chamber design would have to be employed and conventional valve pintles and seats would be necessary.

However, an interesting benefit of jellies is the greater unit volume density which is obtained, i.e., more propellant can be packed in a given space. Another advantage is that the absorption of a pressurized gas, such as nitrogen, is reduced again because of the greater density of this jelly. Also, as stated before, since it would be almost mandatory to include the oxidizer in the jelly suspensoid, a form of mono-propellant is obtained. This would more than overcome the extra pumping and piping complexity needed for the jellies since the flow system itself is naturally simpler for a mono-propellant. Boron or berrylium or aluminum as metallic additives would greatly increase the combustion volume temperature.

A drawback of the jelly propellant is its temperature sensitivity. If the temperature were raised beyond the critical point, the jelly might become liquid and create a serious hazard. Therefore, some means would have to be found either by chemical additive or temperature conditions to prevent this recurrence.

BIG NEWS ABOUT A LITTLE PRODUCT

New "PYGMY" Connectors for Miniaturized Electronic Equipment Installations

Although the newly developed "Pygmy" line of miniature electrical connectors is approximately one third smaller in size and weight than the standard Bendix* AN connector, they provide the same outstanding qualities of serviceability, ruggedness, reliability and resistance to vibration, moisture and corrosion for which all Bendix connectors have become world famous.

If you have an application for miniaturized electronic equipment requiring lighter and smaller connectors than standard AN types, you'll find Bendix "Pygmy" connectors the best possible solution. Write for complete detailed information. SCINTILLA DIVISION OF BENDIX AVIATION CORP., SIDNEY, N. Y.

Aeroballistic Forecasting at Redstone

for High-Punch Missiles

Predicting the influence of natural farces upon giant guided missiles is the difficult job performed by the Aeroballistics Laboratory of the Army Ballistic Missile Agency.

These 20th Century seers would put to shame the Merlins of the past. Instead of crystal ball or occult lore, they employ mathematical equations, meteorology, physics and other sciences to come up with estimates and not guesses.

Heading up this enterprise is Dr. Ernst D. Geissler, whose closely knit team of specialists at this Army Ordnance activity includes 110 civilians and 22 military personnel. Six of them have doctor's degrees in one of the sciences, 20 have master's degrees and 44 are bachelors of science.

Their unique assignment is to forecast the behavior of such missiles as the 60-foot *Redstone* as it roars through the earth's atmosphere and coasts through outer space, then falls upon the target.

"Our predications have so far been quite successful," Dr. Geissler admits. "No change was necessary in the configuration of the *Redstone* due to unexpected aerodynamic characteristics."

Having brought the medium range *Redstone* guided missile to the production stage, the Army Ballistic Missile Agency is now pursuing development of the intermediate range ballistic missile, or IRBM, dubbed the *Jupiter*. This will travel approximately 1,500 nautical miles and can be launched from land or sea.

The Laboratory's success has saved time, materials, and countless dollars. Because of the information developed by Dr. Geissler's group, the Army can hold down the production of test missiles and models to relatively modest numbers. It was for lack of dependable information that the Peenemüende group in Germany was able to launch successfully only 40 per cent of the V-2 rockets developed in the closing phase of World War II.

Dr. Geissler was a member of the Peenemüende group. He was engaged in missile activity since 1940. The year before that he received a master's degree from the University of Dresden and immediately became assistant professor of the Institute for Physics. At Peenemüende he studied the theory of control and stability of guided missiles. When the anti-aircraft missile *Wasserfall* was under development he directed the study of flight mechanics, theory of control and homing.

With his associates he worked out a new method of automatic, three-dimensional homing still in use in ground-to-air missiles. This project won him a doctorate in engineering in 1951.

Dr. Geissler came to the United States in 1945 with Dr. Wernher von Braun and others of the Peenemüende scientists. For the last six years he has concentrated on the *Redstone* missile. He recently became an American citizen.

It takes a well-seasoned mixture of theory and test data to produce reliable predictions of missile behavior. In Dr. Geissler's words, it involves:

"The prediction of aerodynamic lift, drag, stability, pressure distribution, controllability, and forces acting upon missile control vanes for new models is usually based upon a judicious mixture of direct theoretical calculations and extrapolation from existing test data for similar configurations when this information is available."

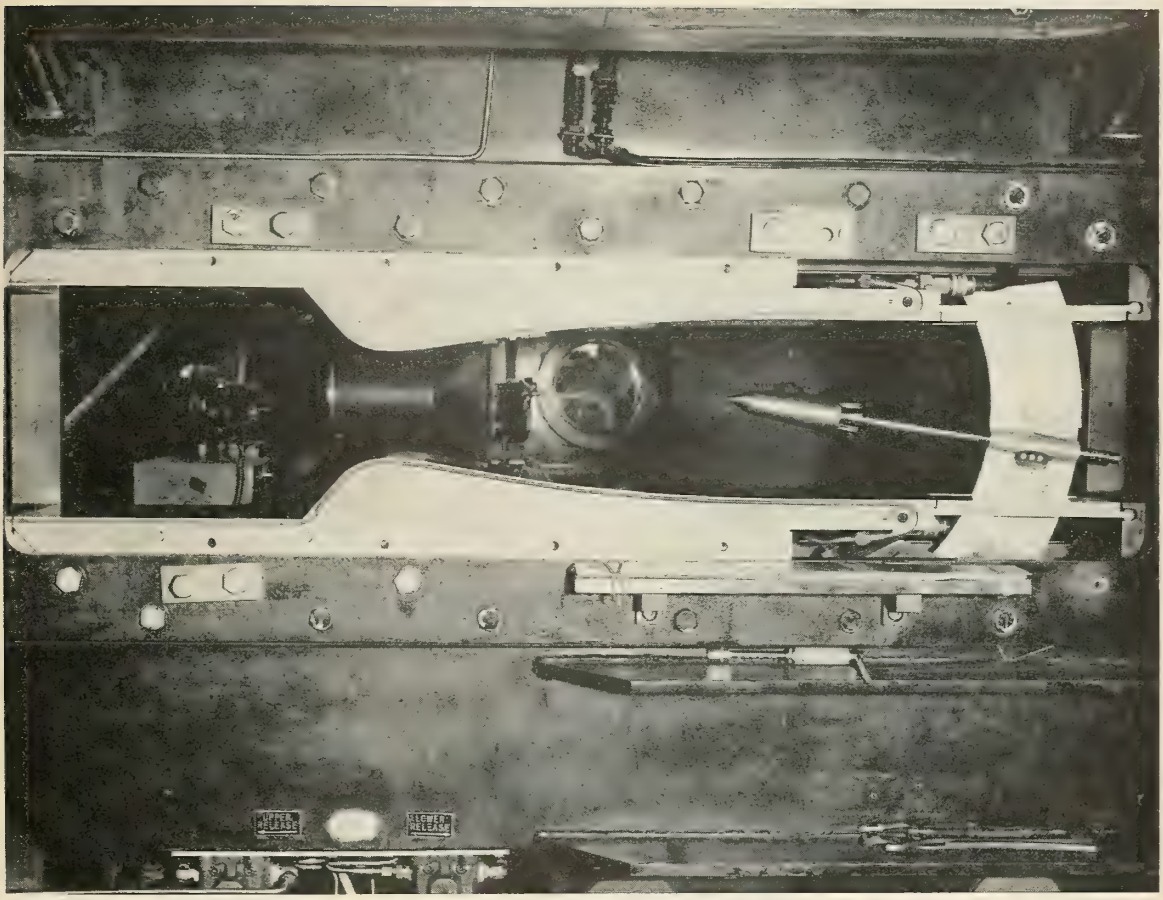
He added that so far, in the progress of the *Jupiter* program, there has been substantial agreement between the estimates of his Laboratory and results of actual test firings.

ABMA employs the services of many other mathematicians and physicists in the aeroballistic phase of its effort by contracting projects. Thus it derives data from wind and blowdown tunnels, and ballistic ranges, located at Aberdeen Proving Ground, Md., an Army Ordnance installation; the Naval Ordnance Laboratory at White Oak, Md., the Arnold Engineering Development Center at Tullahoma, Ala.; Langley and Wright Fields and Lewis Flight Laboratory of the Air Force; Cornell Aeronautical Laboratory, the University of Alabama and California Institute of Technology.

In many cases Dr. Geissler's personnel provide the models and model balances required for tests conducted elsewhere. Usually his representatives participate in the actual testing.

At the Army Ballistic Missile Agency Dr. Geissler has facilities available far superior to those used at Peenemüende. There is a supersonic wind tunnel, for example, and a high pressure jet facility with ranges from Mach 1.5 to Mach 4.5. He considers this wind tunnel a most efficient tool for obtaining aerodynamic data quickly. Installed in the tunnel are strain gage balances and pressure pickups which flash their information during testing through an analog-digital conversion device to an electric typewriter, or through other circuits which punch IBM cards for interpretation later by a massive computer.

Shortly the Laboratory will begin preliminary tests on a transonic and supersonic test section, double the size of the present tunnel, which will be capable of Mach numbers corresponding to speeds of more than 4,000 mph.



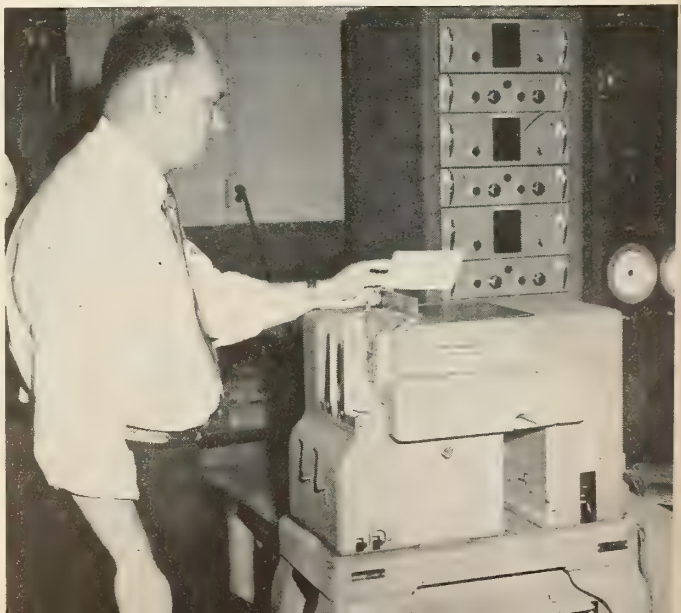
Some of the mathematical problems are so involved that Dr. Geissler pointed out the matter of programming the equations takes considerable time, although the electronic computers which deal with the programmed data can produce results quickly.

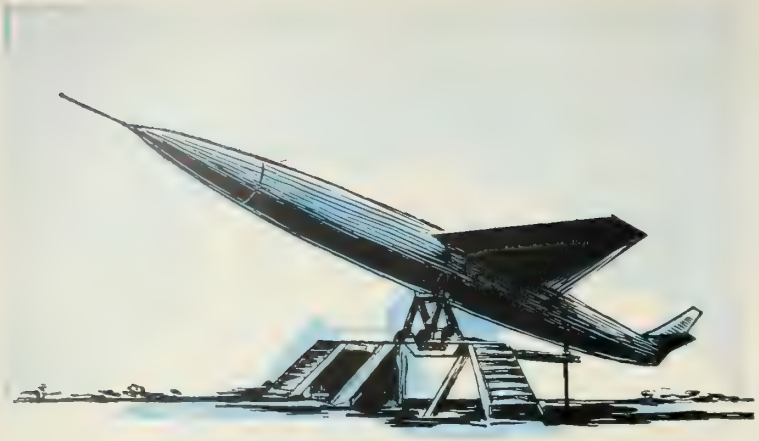
"One wonders," he observed, "if in the development of high speed computers there has been too much emphasis on speed rather than ease of programming. There are cases where much simpler procedures, even desk calculators, are competitive in view of their higher flexibility."

One of the current problems under investigation is the effect of wind upon large missiles. At the so-called "jet stream" level, 30,000 to 40,000 feet up, missiles encounter very high winds. Alabama's Polytechnic Institute is compiling a statistical evaluation of wind measurements for the Army Ordnance Agency as a part of this study.

One of the Laboratory's sections conducts studies of such factors as meteorological effects, wind, density, pressure, temperature variations, altitude, geographical locations, and the season of the year—which also has a bearing on missile performance.

Another section pre-calculates test flight trajectories with the assistance of the Navy's Dahlgren Computation Laboratory. Firing tables for the *Redstone* missile are being prepared by the Aberdeen Computation Lab. These tables will be employed by future Army missile men in the field such as the 217th Field Artillery Missile Battalion—the first unit organized to fire the *Redstone* —which is now in training at the Agency.





Missile model is pictured in position for aerodynamic testing in the Aeroballistics Laboratory wind tunnel chamber. High-pressure jet facilities are capable of testing within ranges from Mach 1.5 to Mach 4.5.

DR. ERNST GEISSLER, Director of the Army Ballistic Missile Agency's Aeroballistic Laboratory, is shown inspecting various models of missile warheads used in wind tunnel tests. This lab is assigned the mission of forcasting the behavior of Ballistic Missiles on the path of their flight from the firing base to the target.

Cards are automatically punched for later interpretation when information from wind tunnel tests is picked up by strain gage balances and pressure pickups and flashed to the electronic computing machines.

When it has to be heated rely on Safeway Woven Heat Elements

. . . and the "it" can be just about anything from a simple tray to the curing blankets for honeycomb structures.

Safeway Woven Heat Elements are custom tailored to fit specialized requirements of many applications. A single aircraft, for example, may need upwards of 80 different heating and de-icing elements, all of which are made by Safeway. Other applications are on helicopter rotors, rocket tubes, missile launchers, and on a wide variety of molds, dies, tanks, ovens and dryers in industry.

If you have a problem that requires heat, let Safeway engineers study your requirements and—without obligation to you—submit an appropriate recommendation.

Aerojet Expands Architect Engineer Services Division

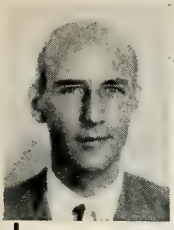
Aerojet-General Corp. keeps expanding scope of its Architect-Engineer Services division.

Located at Covina, next door to the company's headquarters at Azusa, this division now has more than 600 architects and engineers. It provides such specialized services as static test instrumentation, flight-test range instrumentation, high-speed test tracks, rocket test stands and launching facilities, and complete propellant-handling systems.

One of its present major projects is the construction of facilities at Fort Churchill, Canada, for the launching of upper-air research vehicles during the International Geophysical Year.

Zip Fuel Sources For Ramjets

A U.S. Geological team is conducting a study of Southern California's unique dry lakes, seeking new reservoirs of boron, lithium and other non-metallic minerals. These elements have many uses, but high-energy fuel developments now add greatly to their value.



The so-called zip fuels for which these materials are required are just on the verge of coming into their own. Any problems that existed as regards their use in ramjet engines have been surmounted. At the same time, progress has been made with respect to turbojets.

For many years, the dry lakes and desert areas of Southern California have produced 95% of the world supply of borates. More than $25,000,000 worth of chemical products were mined from one of these dry lakes, Searles, in 1956. Hundreds of these lake beds dot the Mojave desert, but probably less than a score have ever been worked commercially. Only about six are being mined now.

Marquardt Named In Nuclear Propulsion

Marquardt Aircraft Co., producer of the ramjet engines for the Boeing *Bomarc* missile, has been named a prime contractor in the Air Force aircraft nuclear propulsion program.

President Roy Marquardt said the company is now engaged in studies directed at development of advanced nuclear propulsion systems.

Propulsion Notes

By Alfred J. Zaehringer

According to Bulganin, Soviet chemical production is to be stepped up. Pravda claims the new 1960 capacity is to be 91% over the 1955 mark. Among others, this reflects the expanding missile propulsion demands. Also, all satellite chemical industry will be integrated to form a huge Soviet centered chemical cartel.

The big guns in Soviet ballistic missiles are all of the lox-hydrocarbon type. Most widely used fuels are heavy gasolines, kerosenes, or fuel-oil grades. Apparently the difficulties associating the hot and heavy fuels have been solved indicating solution of combustion instabilities, hot spots, burnouts in large motors. All the big Red rocket motors operate at high pressures (viz., 500-1,000 psi).

•

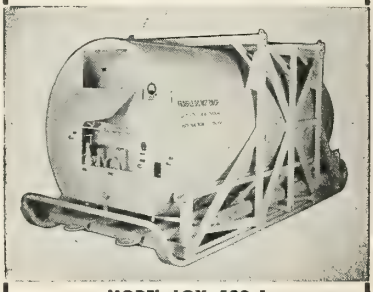
Russia is increasing its output of nitric acids and ammonia. However, nitric acid engines have only been used for smaller rockets (such as manned aircraft or AA). However, the USSR appears to be better sold on peroxide than the US in that they have at least one operational peroxide-propelled surface-to-air missile. Production of peroxide was recently doubled in Russia and also may be in for another increase under the new five-year plan.

•

Increased amounts of ammonia will be going into ammonium nitrate for solid propellants. The Reds invested heavily in basic ammonium nitrate research and the payoff is coming in the form of increased use of these low cost materials for RATO, boosters, and long duration sustainers. The 1960 production goal of about 1 million metric tons of rubber and related synthetic resins implies trends toward increased use of new composite propellants.

•

The M-100 guided aircraft rocket has been drastically redesigned along with a rough halving of package size. The powerplant thus may be using ammonium perchlorate or some other high-energy solid in place of the old potassium perchlorate type propellant. Scale-up of solid propellant powerplants has been successful and operational units are operating at the ½-1 million lb-sec level. Further increases are anticipated. Most of USSR solid propellant development seems to be riding on composite propellants. Double-base propellants, however, are still being used for boosters, unguided aircraft rockets, infantry and artillery weapons. Big blank is new solid monopropellant work.



•

Status of exotic fuel production is unknown. However, turbojets and ramjets are well trenched in the USSR aircraft and missile line. Most ramjet efforts are currently going into long-range, cruise-type, attack weapons. Work also appears to be in progress on nuclear propulsion (See m/r Oct., 1956). Present Russian thinking is quite conventional—the use of a working fluid (such as hydrogen or water) in conjunction with an atomic pile. Studies also have been reported on the direct utilization of high-speed nuclear particles, ion, and photon-type systems.

•

Rocket powerplant development and production centers are located at Leningrad, Kasan, Kuibyschev, and Irkutssk. The entire system has its headquarters at ZIAM Institute in Moscow. Important test stands and ranges are at peenemünde, Kalinin, Uralskaje, Tomsk, and Kara-Kum.

How to get reliability

Got the automation jitters?...worried about turning complex manufacturing operations over to an "electronic brain"?...worried about what can happen when one component in the control system fails?...

Reliability takes on a new and different meaning as American industry becomes more and more automated. Here are a few thoughts on the importance of reliability and how it can be controlled.

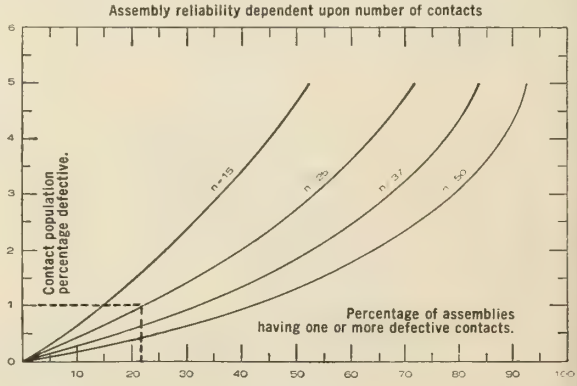
All of us are going to have to pay more attention to "reliability."

We'll have to pay more attention to individual "devices" within a system.

We'll have to guard ourselves carefully when we design the entire system.

The industrial pendulum is swinging more and more toward automatic controls, servo-mechanisms, computers, and automatic "watchers." As it does, the reliability factor becomes more and more important. Let's see why. For example, you probably have three radios at home. If one fails because a soldered joint comes apart, your home life is probably not disrupted to any alarming degree. But... consider the automatically controlled steel mill. One soldered joint failing, unless all controls are installed in duplicate (which is expensive) could tie up the entire production process for valuable minutes, if the maintenance crew has second sight. For hours, if automatic trouble-indicating and locating systems are not installed (and these are expensive, too). Last, but not least, lend a thought to the dependence of guided missiles and man-made satellites upon the reliability of electronic circuits and components. So... let's start to examine "reliability." Let's begin by looking at this definition which is currently popular in the technical field:

The reliability of a particular component or system of components is the probability that it will do what it is supposed to do under operating conditions for a specified operating time.



Now... this is a relatively well-accepted definition, and it offers the key to the problem of coping with failure control. Take the word "probability" in this definition. Let's discuss its implication.

Many of today's systems, simple or complex, are a chain of components. So picture a system as a chain with its successive links. In the field of statistics the over-all reliability of the chain is the mathematical product of the reliabilities of the individual links...

Overall Reliability, $R_o = r_1 \times r_2 \times r_3 \ldots r_n$

Now, let's consider a system made up of 100 different components, each of which has a reliability of 99%. In applying the formula, multiplication of .99 by itself 100 times gives an over-all reliability for the system of only 36.5%. Two out of three systems you have put together will probably fail!

Cannon becomes involved with this problem because our main business is making electric connectors. So, let's look at the following chart that covers contact reliabilities and reliability of the assembly in which they are mounted.

This chart illustrates the reliability of four connectors having 15, 25, 37 and 50 contacts respectively. As an example, assume that the contacts have a contact population of 1% defective (1 in 100 defective... this percentage is considered a fairly high standard in most fields). On the 15-contact assembly, we find from our chart that 14% of the connector assemblies would have one or more defective contacts! With 25 contacts, 22% would have one or more defective contacts. With 50 contacts, 41½%... is your hair starting to curl? Obviously, a 99% contact reliability standard for guided missile components is absolutely unacceptable. And, in between the simplest system and that of a guided missile, are hundreds of assemblies and systems whose reliability factors must be analyzed with utmost care.

But all is not lost! There's another side to the picture. With proper care, analysis, and control, our Cannon organization has actually achieved, in special "missile quality" contacts, a known level of only 2.85 x 10^{-3}% defective... only 1 part in 35,000! Naturally, we don't achieve that with all our contacts... but we do try to design and manufacture the utmost in reliability required for specific applications.

We have pictured this chart to show the direction we must all take, whether we're talking about connectors, other components, or systems. It boils down to two steps...

- The number (n) of components must be kept low ... *simplicity*.
- The level of component reliability must constantly be improved ... *hard work for all of us*.

Now... if we refer to our reliability definition on the previous page we note the phrase "do what it is supposed to do." So be sure *you* define these objectives for your component assembly, or system... failure to do so carefully can cause undue failure or the expenditure of unnecessary dollars for needless, excessively-reliable parts or design.

Further on in the same definition, we note the words "operating conditions." This brings up many new points for consideration. Here we are concerned with such things as temperature, pressure, humidity, corrosive atmosphere, stray electric and magnetic fields, low and high frequency noise, shock and vibration. Do your design standards need upgrading? Are your components designed and then tested to meet the operating conditions you specify... or are they designed to meet "average" conditions? Are you using adequate "safety factors"?

In a simple component, manufacturers have always looked for, recognized, and corrected faults when they occurred. We use component quality control to achieve and maintain Cannon's world famous product quality. But in complex systems such component quality control is not enough. Actually ...

Reliability control over the system is needed. It should be all-encompassing. When you get right down to it, *reliability* is the product of procedures, equipment, and people... in the design, manufacture, testing, control of quality, transportation, and use of products or systems.

Do you have a reliability control system?

Here are a few of the steps that are needed to get a reliability control system operating:

1. Determine Your Requirements. Specify the environment, operating time, performance limits, and the percent of reliability required. Allow an adequate safety factor keeping in mind the end use of the finished product.

2. Collect Reliability Data. Set up facilities for the continuous accumulation of data on component or system failures and their causes.

3. Establish quality control and test procedures which show high degree of correlation with end-use conditions.

4. Analyze. Determine if reliability requirements are being met. Establish the most important causes of failure by analyzing the data you collect.

5. Improve. Take action to eliminate the most important defects or causes of failure. Reduce the failure rate to the required level.

6. Maintain Continuous Vigilance. You have emphasized system design... you have used statistical analysis of failures... now exert continuous and critical control to be sure your "improvements" actually improve reliability. Examine new and unforeseen failure sources. Review and modify your requirements with changing conditions.

*

We at Cannon Electric are proud of our historical emphasis on quality and reliability. Since 1915 we have adhered to a design philosophy embracing the highest quality and reliability in each and every Cannon Plug for the specific application for which it is to be used. *If we can't design to that principle, we don't make it!* In manufacture, we are proud of our know-how in depth, proud of our fine quality control systems, proud of our personnel and proud of our reliability control group.

Whenever *you* have an electric connector reliability problem... in design, engineering, production, or prototype phases... we would appreciate the opportunity of discussing it with you.

Cordially,

Robert J. Cannon *President*

CANNON ELECTRIC COMPANY

Approach to Solid Propellants

The key to the future growth of solid systems may well lie in processing techniques. We already have seen that we may be nearing the limits of chemical energy release in working systems.

In developing solid propellant systems cognizance must be taken of the present state of the art and projected developments. Due to present exigencies, we cannot be too specific about current systems. However, there is enough available data to give us a view of orders of magnitude.

Although homogeneous solids (viz., single and double base and colloidal propellants) released us from the shackles of the once standard gunpowder, they have somewhat restrained growth. Certain innate properties as high cost, low stability, and high sensitivity previously had given us a false view of the entire solid field. However, because of such factors as high burning rates and a large technological background, they are likely to remain in the picture for some time.

The advent of modern composites has, to a certain extent, released us from many of the shortcomings of homogeneous propellants. However, although we have tremendous possibilities with composites, our limiting factors are likely to rest on choice of oxidant. With large number of available fuel-binders, the composite field probably will be the most flexible in offering custom propellants.

The composite solid system is likely to be a stopgap field until we can synthesize a true, ideal solid monopropellant. Unfortunately, our knowledge of progress in the solid monopropellant field will be obscure for some time to come.

The gap between solid and liquid systems has been bridged by recent work, in hybrid systems. Performances greater than existing pure systems have been revealed at only slightly greater complexity.

Competing with Liquids

Designers now will be interested in a comparison of solid and liquid systems. Despite the fact that data may be restricted, a comparison is very favorable. Other factors such as handling, storage, reliability, etc. should be considered also.

Two Avenues of Approach

For the present and future, solid propellants have two avenues of approach in competing with liquids. For one, we can limit the field (by such factors as cost, applications, etc.). Or, we can take the unconventional approach. One technique to lower costs, for example, would be to design a system which yields a valuable by-product. That is, we would wind up with a propellant which can sell for less than that of its raw ingredient costs.

The general field of solid propellants has experienced a tremendous growth in a short period of time. Solids now compare very favorably with liquids. Hybrid systems now offer the possibility of bridging the gap between solids and liquids and make wider use of existing technology. Motor designers thus will have an extremely wide choice of high performance propellant systems. Designers of both active and inert systems should strive to maintain and better the present high degree of reliability in solid propellant systems.

ORIGINAL DESIGNS FOR HIGHER RELIABILITY IN GLASS-HOUSED RESISTORS AND MINIATURE RELAYS FOR ALL PURPOSES

Astrionics

By Henry P. Steier

Russian and other IGY delegates meeting in Barcelona last fall agreed to the resolution that both U.S. and U.S.S.R. satellite programs operate on the U.S. chosen 108 megacycle radio tracking frequency. At that time, Russian delegates announced they would "provide further data when ready" on their planned instrumentation load and satellite diameter.

Nothing further on Soviet astrionics has been heard officially from U.S.S.R. Oddly, latest news indicates the Soviets are maintaining their previously disclosed line in satellite thinking. It has come from Russian broadcasts beamed to Far Eastern countries. Members of the U.S. IGY Committee have been studying transcripts of the intercepted broadcasts with great interest—particularly in the inconsistencies with our program. Broadcasts are quoted as saying the U.S.S.R. satellites "ought to be" the size of ours but with a higher payload. Despite this rocket motor figures given are copied after ours.

If and when our "competing" satellites get up there first, the competition should not be felt in Russian scientific circles. Full data on what we find was promised the Russians through the International Council of Scientific Unions in Brussels. This ought to allay the fears of those who fear "pirating" of data stored in the U.S. satellites during each revolution.

As things stand now it's the high school kids and other potentially over-zealous amateur experimenters that worry U.S. satellite scientists about pirating. Since the stored information must be "dumped" by a signal from the ground at the right time, both deliberate and unintentional signals could wreak havoc with experiments. Naval Research Laboratories' John T. Mengel, who is the brains behind the satellite transmitter design, informs us the satellites will have their own "security system" designed to foil unauthorized dumping. He says it's not the utmost in security but is the best we can do with payload available.

Secret is "a couple of audio tones," Mengel says. Satellite astrionics will respond only to an rf signal modulated by this particular combination of tones. This is a hard one to beat. It's been very successful in airline Selcal, selective calling, systems. Specific combinations of audio tones enables airlines to call specific aircraft. Each plane responds only to a particular combination of tones to which it is tuned.

•

It's the little things that count. Among these in the Vanguard program are the gyroscopes being built by Minneapolis-Honeywell to control the vehicle's orientation to within 2.9 degrees. Outside that limit anything can happen. Observers who have toured Free Europe's laboratories say work there on producing super-accurate gyros is nil. What the Russians have in the way of inertial guidance is not known. Despite importance of propulsion, these "little things" could make or break the success of a scientific or military rocket vehicle design.

•

Another "little thing" is transistor technology. The Russians are now beginning to talk about transistor developments. These will be of first importance in our satellite astrionics gear. Russian talk of transistors is mainly in the computer field. They appear to have built very fast and large capacity data processing machines which they are beginning to transistorize. As with our IGY program, Russian satellite experiments would depend heavily on rapid and powerful computing machinery.

To the ENGINEER of high ability

Through the efforts of engineers The Garrett Corporation has become a leader in many outstanding aircraft component and system fields.

Among them are:

air-conditioning

pressurization

heat transfer

pneumatic valves and controls

electronic computers and controls

turbomachinery

The Garrett Corporation is also applying this engineering skill to the vitally important missile system fields, and has made important advances in prime engine development and in design of turbochargers and other industrial products.

Our engineers work on the very frontiers of present day scientific knowledge. We need your creative talents and offer you the opportunity to progress by making full use of your scientific ability. Positions are now open for aerodynamicists ... mechanical engineers ... mathematicians ... specialists in engineering mechanics ... electrical engineers ... electronics engineers. For further information regarding opportunities in the Los Angeles, Phoenix and New York areas, write today, including a resumé of your education and experience. Address Mr. G. D. Bradley

AiResearch MISSILE AUXILIARY POWER UNIT

Compact, reliable system features high output with simplicity of design

This AiResearch auxiliary power package operates the vital electrical and hydraulic systems in a missile.

Gases from a solid propellant spin the unit's turbine wheel at 50,000 rpm. The turbine's shaft drives the following: a 650 watt generator which supplies electrical power to run the missile's guidance system; a 35 watt generator which runs the missile's gyros; a hydraulic pump which in turn powers the servos that control the movable flight surfaces of the missile's airframe.

The hydraulic system features drilled passages which eliminate the need for potentially troublesome plumbing. It includes reservoir, filters, temperature compensator, relief valve, check valve, and squib valve within a single housing.

This auxiliary power system is an example of AiResearch capability in the missile field. Inquiries are invited regarding missile components and sub-systems relating to air data, heat transfer, electro-mechanical, auxiliary power, valves, controls and instruments.

SPECIFICATIONS:

Output: 650 watts, 5000 cycles, 115 volts, single phase
35 watts, 400 cycles, 115 volts, single phase
0.6 gal. per min. at 2000 psi hydraulic pressure

Regulation: ± 5% voltage and frequency

Duration:	27 seconds
Weight:	9.5 pounds
Size:	6.14 in. diam., 6.74 in. long

Ground power: compressed air

Outstanding opportunities for qualified engineers

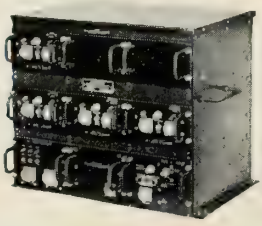
TDI MINIATURE TELEMETRIC RECEIVING SYSTEMS



Miniature and mobile, here's a telemetric receiving system designed for a host of military and civilian applications . . . airborne, ground or marine!

For missile checkout, flight tracking experimental aircraft and missiles, the TDI systems are highly effective, even under the most severe field service conditions. They operate ideally with tape recording, oscillographic, photographic and similar types of recording equipment . . . and this rugged equipment can be installed in jeeps, autos and trailers.

Design-wise, these systems achieve substantial reductions in weight, size and power consumption—yet a high degree of accuracy, exceptional stability and simplicity of operation are maintained.

TDI 12-Channel Receiver. Modular construction permits wide flexibility of arrangement and actual form factor of receiving equipment. Packages or combinations in any number from one to eighteen units can be arranged in various mounting styles.

TDI Type 2701A 4-Channel Receiver. Use as flexibly as 12-channel unit—split up in combinations to suit your particular receiving requirements. Ideal for flight line checkout.

← Telemetering on wheels! New portable test cart enables users to perform wide variety of telemetering functions in previously inaccessible locations, with greater efficiency and accuracy than ever before.

Technical bulletins on miniature receiving systems and other TDI products available on request.

TDI's newest office is now located at 305 Washington Avenue SE, Albuquerque, New Mexico

NEW

Rotary Actuator for Missiles by EEMCO

....has a gear reduction of 135 to 1 in a length of but 2.25 in., weighs only 6.75 pounds.

SPECIFICATIONS FOR TYPE D-925

Type: Rotary actuator for missile fin actuation
Output: 400 inch-pounds @ 64 RPM, 24 volts, 27 amps
Duty Cycle: 1 minute on, 10 minutes off
Gear reduction: 135 to 1 in 2.25″ length
Weight: 6.75 pounds

This new light-weight, compact rotary actuator by **EEMCO, Type D-925,** was designed for fin actuation in one of the nation's latest missiles. Here, as in all other applications of **EEMCO** actuators and motors, it must operate unfailingly under the extreme environmental conditions that are encountered at ultrasonic speeds in stratospheric altitudes.

Type D-925 rotary actuator has a self-contained 28 volt DC motor with clutch, and 400 inch-pounds of output at 64 RPM on 24 volts, 27 amperes. Duty cycle is 1 minute on, 10 minutes off.

✳ **EEMCO** is a specialist in the design and manufacture of precision actuators, both linear and rotary, and special motors. **EEMCO** products are on the majority of the latest supersonic military aircraft and missiles. Therefore **EEMCO**'s many years of experience in this field, exclusively, is aiding materially in the delivery of the latest aerial weapon systems for the national defense in which reliability of performance must be unerring.

Missile Miscellany

Where do you get your ideas? Try these: A rocket company with contracts and profits is making a missile in the shape of a sphere to operate in either air or outer space . . . At Hialeah last month, the Hibiscus Stakes, the favorite, Missile, lost to Honest Man . . . At a bar the other night, an AF officer declared that the Thor that goofed was "a production model" . . . same bar, same night this page heard odds quoted one-to-one the Vanguard would not be the first man-made vehicle to orbit the earth, or escape.

★ ★ ★

Has anyone ever used modern theory to explain why the silicate, Lintz basalt, spontaneously generates heat at a rate of 2.36×10^{-4} calories per hour per gram; why in free fall it won't accelerate at 980 centimeters per second^2? It's not radio-activity, for uranium is 1500 times as active as Lintz basalt, generates only 7.2×10^{-5} cal/hr/gm.

★ ★ ★

Lunch with this page's NACA structures engineer brought the observation that up to ICBM man had always been able to borrow from nature. Now reentry temperatures were known only at the sun's surface, the earth's center or in the stratosphere when meteors burn up. But what about meteors that make it down? What's the aero- or thermodynamics behind the myriads of spherical holes that pock their surface? And by mail, a missile valve and piping man wonders if anyone's tested the metal from Arizona's big meteor in missile applications.

★ ★ ★

A reporter member of ISAW, commenting on Pentagon policy of misleading the American public by letting them think the 3300-mile Jupiter-C missile is a Jupiter IRBM, suddenly asked: "Say, I wonder if Wilson's gone to Florida really to see the first full Jupiter fire?"

★ ★ ★

At home one night discussing the many and the varied with a working physicist, this page was asked: "Why not take the obsolescence out of education, start teaching the thinking of Field Relativity Theory in grade school when it's new and logical, instead of later when it's contradictory and disturbing; let it grow with the young, inquiring mind and perhaps, like that mind, expand?"

★ ★ ★

Then, in New York at the recent Institute of Aeronautical Sciences meeting, an Admiral unofficially insisted that the missile-equipped Navy of the future will have to go 100% underwater, and that once it does, its missile ability will top Army's and AF's.

★ ★ ★

With cracks like "Snark-infested waters" and the "Thor Myth" going about, it's no surprise a recent failure of another missile to make it farther than the adjacent launching pad leads to the AF quip: "Have you heard about Army's latest Inter-Pad Ballistic Missile?" . . . with the progress being made in jellied propellants, why can't later models of the Polaris be "liquid" after all . . . AF now forbids its civilian scientists to voice impressions of Soviet scientists on the grounds of military security "in the international political field" . . . from a manufacturer of high temperature materials like brake linings, an offer of a laminated reentry nose cone that will take 6000 degree boundary layer temperatures for 18-20 seconds . . . and just in case you thought the reaction motor was something new, Heron's steam driven Aeolipile amused the Greeks in 300 B.C. . . .

INDUSTRY SPOTLIGHT

By Joseph S. Murphy

Civil Application of Missile Know-how

Some missile principles and techniques are being applied to consumer industries with surprising success. The fact that missiles are of a highly technical nature and that the military have top priority in their research, are not valid reasons for holding up consumer industrial progress in any way. Rather, research men are "squeezing" every drop of helpful information possible from their pool of guided missile information and data.

Guided missile work has already proven useful in these consumer fields in the design of propulsion systems, airborne navigational aids, and machine tools. Research on upper air phenomena, miniaturized electronics and precise automatic computers are of more recent vintage.

Future aircraft fire control systems are in advanced stages and are of a classified nature. They include the design and development of systems to meet the tactical and strategic requirements of new bombers, fighter-bombers, and interceptor aircraft.

Other improvements for the future are new techniques in integrating flight control computer and radar functions of fire control systems that will make present-day computing gunsights obsolete.

Impact on Industry

Needless to say, fire control systems, missiles, and their components have had a tremendous impact on industry as a whole. They have undoubtedly had a great deal to do with the estimate of a leading firm that today one out of every eight workers in the company is a technical employe. In 1943 the ratio was one out of every one hundred.

One of the chief industries to be influenced by this surge in technical employment is the electronics field. This is especially true of military aircraft fire control systems where more tubes are being required.

Already the U.S. Air Force for 1957 has allotted 17.3% of its aircraft procurement budget for electronics. In 1952 less than 10% was spent. Airborne radar requirements, for example, have increased from $11.4 million in fiscal 1955 to $35.6 million in 1957. Electronic countermeasure equipment requirements call for $195.5 million in fiscal 1957.

Within these figures lie jobs—many jobs—technical as well as semi-technical and even non-technical. More jobs, of course, mean less unemployment, more buying power.

Right now the guided missile and weapons field is literally begging for engineers and technically trained personnel for careers in aerodynamics, electronics, propulsion, optics. Hundreds of ads appear in magazines and newspapers daily, seeking engineers and scientists with creative skills in aircraft and missile systems.

The job of developing missiles and weapons systems has been dropped in the lap of industry and, in come cases, almost abruptly. At no time in history, however, has there been closer cooperation between industry and the Armed Forces of our Government for the development of these defense weapons. Never has industry held such crucial and great responsibility. Industry's performance in utilizing its facilities and talents to the utmost is the key factor in the keen competition shown and is largely responsible for the progress we have made to date.

In the past there were grumblings about industry being shouldered with responsibility but hampered by (1) ignorance of long-range Armed Forces needs (2) by the state of the development art and (3) by inability to get a decision out of a "complex uniformed bureaucracy." In many instances these grumblings were justified. This should not be the case now. Industry must now "carry the ball"—all the way.

Fortunately, the discoveries coming from today and tomorrow's fire control and missile developments by American industry have not been for war alone. Many great possibilities exist for the future and a world of peace.

Today's automatic pilots and remote control devices in missiles can be put to work to control the flight of aircraft when human ability is not adequate because of high speeds or atmospheric conditions.

Automatic instruments inside a missile can steer an explosive warhead directly to a ground target. These systems can be geared to a compass for direction, to an altimeter for height of climb, to a propeller that acts as a odometer for distance, to a telescope that navigates by watching the stars, or even to a television set that looks for a spot on the ground.

Why can't similar systems be devised to land high-speed aircraft on the runway in any weather or visibility? In fact, why can't such a robot craft be used to deliver important documents or much-needed serums or drugs in emergencies to distant places in short time, regardless of weather—a sort of "missile-mail" service?

New and greatly improved automatic computers are beginning to run offices and factories.

Because of the need for sending technical information to the ground from a test missile, telemetering has appeared. This is nothing more than measuring conditions on a vehicle in flight and radioing the information back. The telemetering principle is already being followed in earthbound machines. Information is sent automatically from one part of a machine to another, used (again automatically) to direct the whole machine's operation. This, the feed-back mechanism, is leading us toward "automation."

Such a missile guidance system would have to be modified to land a plane. It could be redesigned to control the flaps at a certain time, level out, and stop engines. Information obtained by radar could be fed into a computer which could calculate exactly when and how much to begin braking.

It is not inconceivable that directional forward firing rockets, automatically controlled by instrumentation originally developed for missiles, could gradually bring a plane about to crash to almost zero velocity before impact.

These are but a few of the peacetime possibilities that exist for missiles and rockets in the future.

Industry Highlights

By Fred S. Hunter

A well-known household remedy, milk of magnesia, is being used successfully by North American Aviation as an inexpensive thread lube. Before milk of magnesia was tried, North American had been experiencing a high breakage rate on bolts and clamps on stress relieving and welding fixtures placed in ovens for post-forming operations. Application and removal of milk of magnesia is easy, says Ed Cane, conservation committeeman in the missile detail department at Downey. It is daubed on threads with a brush; after removal from the oven it is in powder form and is easily dusted off.

Lockheed's Missile System division has installed a new Baldwin 440,000-pound hydraulic universal testing machine in its engineering laboratory for its structures test group and it would, of course, be dubbed *Big Bertha*. It is able to test components up to 65 inches wide, 11 feet long (in tension) and 12 feet long (in compression) in its vice-like arms. The $36,000 machine's four load ranges read to an accuracy of plus or minus ½%.

At this writing, all Boeing has announced is that it has options on land in the San Ramon Valley in California for possible construction of a *Bomarc* production plant and on the Ford Motor Co. plant at Richmond, Calif. But word is being freely passed around that the joint plants of the Seattle manufacturer and the Air Forces will involve a total investment of $100,000,000 for plant, equipment, etc. Seems like a pretty large sum even though *Bomarc* is a pretty large program.

A U.S. Geological team is conducting a study of Southern California's unique dry lakes, seeking new reservoirs of boron, lithium and other non-metallic minerals. These elements have many uses, but high-energy fuel developments now add greatly to their value. For many years, the dry lakes and desert areas of Southern California have produced 95% of the world supply of borates. More than $25,000,000 worth of chemical products were mined from one of these dry lakes, Searles, in 1956. Hundreds of these lake beds dot the Mojave desert, but probably less than a score have ever been worked commercially. Only about six are being mined now.

Rocketdyne has installed a new emergency telephone system that makes good sense. Employes at the main plant in Canoga Park dial 333 and those at the Santa Susana test facility dial 555. This puts 'em through to the central control operator. A new-type of number disk is being placed on all Rocketdyne telephones. In addition to telephone and extension number usually found on these disks, the correct emergency number will be listed and the telephone location, such as Room 27 or Column 00.

Raytheon's new laboratory opposite the Santa Barbara airport for the design of electronic and infrared equipment for the government is scheduled to be ready for occupancy by mid-summer . . . More than 40 of Aerojet-General's Aerobee sounding rockets will be launched during the International Geophysical Year program at the launching facility installed at Fort Churchill, Manitoba . . . North American's transplanted Californians were treated (?) to a brand new type of weather at Rocketdyne's Neosho, Mo. plant when 1.48 inches of rain, snow and sleet broke power lines, knocked out telephones and completely stopped work at the plant . . . Art L. Hubbard, recently named to head the newly established systems test facility department of Lockheed's Missile Systems Division, was the first employe selected by the division to attend UCLA's two-year engineering executive program begun last year.

limitless...

Poly-Scientific's newly perfected manufacturing processes permit limitless variation in design . . . every part custom made to your individual requirements.

Poly-Scientific is synonymous with versatility, precision, and performance. Every slip ring, commutator and brush assembly made by Poly-Scientific is the ultimate in quality.

The use of epoxy resins allows greater miniaturization without sacrifice of strength. Our perfected techniques permit the use of any of the noble metals and alloys, making possible the selection of the optimum material with the proper hardness for each specific application.

Dependable, long-life performance . . . minimum generated noise . . . freedom from tarnish . . . dimensional accuracy and stability . . . all of these are **automatic** when you specify Poly-Scientific. And best of all, prices are competitive.

miniaturized slip ring assemblies
brush assemblies
commutators
to fit any requirement

A real achievement in sub-miniaturization: thirty-two 0.140" diameter rings in less than one inch of length, with no sacrifice of electrical or mechanical characteristics! Rugged and accurate stainless steel flange and center rod insure perfect alignment. Solid coin gold rings of 140 Brinnel hardness are finished to a high polish. Also note color coded teflon insulated leads.

This extremely accurate commutator, used to generate a critical impulsing sequence, is fabricated with coin gold segments common to the end contact and P-30 epoxy resin, the combination of which guarantees uniform wear and long life.

New Missile Contracts Announced

Commerce Department's synopsis of new Defense contracts at presstime listed four new awards to missile and rocket firms.

Douglas Aircraft Co.-Santa Monica received three contracts totaling $2,340,083 covering facilities for *Thor* WS-315A medium range ballistic missile production.

Thiokol Chemical Corp. of Elkton, Md. won a $1,520,527 award to produce M-58 rocket engines for *Falcon* missiles and Phillips Petroleum Co. of McGregor, Tex. a $442,000 contract for JATO development and production facilities.

Hycon Manufacturing Co. was awarded a $404,000 contract to produce missile test sets.

Interstate Gets $½ Million Order

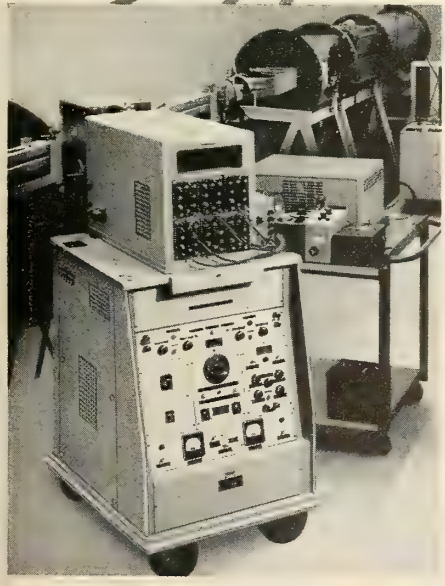
Interstate Engineering Corp. has received an order valued at approximately $500,000 from Consolidated Western Steel Corp. for production of rocket launcher cylinders for the *Nike-Hercules.*

The company also produced similar cylinders for the original *Nike.*

Sperry Sets Up Air, Surface Armament Divisions

Sperry Gyroscope Co., Div. of Sperry Rand Corp. has established two new divisions—an Air Armament Division and Surface Armament Division.

The Surface Armament Div., under Myron D. Lockwood, has been assigned responsibility for original development, design, manufacture and sales of ground, shipboard and submarine armament products.



The Air Armament Div. headed by Samuel Agabian, will have similar responsibilities in the fields of air armament, missile guidance systems and navigational equipment.

Cornell Developing New Test Facility

A new hypersonic test facility capable of testing aircraft and missile designs at simulated speeds of 10,000 mph and 9,000°F temperatures is being developed by Cornell Aeronautical Laboratory, Inc.

Feature of the new installation will be its test endurance. It is said to be capable of maintaining the high-velocity, high temperature airflows for peri-

tomorrow's hypersonic speeds are being measured TODAY...

with the HATHAWAY SC-16B CATHODE RAY RECORDING OSCILLOGRAPH

If your tests demand accurate, time-resolved records of realistic high-speed phenomena experienced during test runs of millisecond duration, the SC-16B is absolutely essential.

Problems beyond the galvanometer oscillograph range, such as Mach 20 conditions, 20,000°K temperatures, dissociation, thermal radiation and mass ablation, are being recorded with this mobile instrument.

The dependable, self-contained SC-16B is specifically designed to meet the many requirements of today's research. It records up to 6000 in/sec within 16 instantly selected chart speeds and has a frequency range from DC to 200,000 cps.

Detailed specifications will help show you how important the SC-16B can be in your application.

Farnsworth

HAS THE ANSWER

...before the button is pushed

Four... three... two... one... Fire! a tense finger pushes a button.

WHOOSH... and a fiery missile unerringly heads for its target. It worked!

Of course, it *had* to work. In atomic warfare there's no second chance. Farnsworth, a division of International Telephone and Telegraph Corporation, developed the uncanny electronic test equipment that knows—*before* the button is pushed. This not only avoids costly mis-fires or missed targets—it actually safeguards our very lives.

This is another answer supplied by Farnsworth Electronics Company, where scientists and engineers of many related skills are applying the vast experience and facilities of IT&T to solve many complex problems in the fields of electronics and communications for industry and the military.

Farnsworth

CAREER OPPORTUNITIES: There are important new openings on our professional staff for graduate engineers and scientists. Write for complete information. Confidential.

FARNSWORTH ELECTRONICS — A DIVISION OF IT&T

ods up to 15 seconds, far longer than before possible.

The $2 million facility is an Air Force funded project that uses a new wave superheater described as a unique arrangement of tubes capable of producing a continuous flow of high-speed hot air.

Lockheed Missile Division Forms Two New Units

Two new weapons system organizational units have been formed under Lockheed Aircraft Corp.'s Missile Systems Division in its new Palo Alto and Sunnyvale, Calif. facilities.

Heads of the new groups will be John H. Carter, MSD associate research director and Stanley W. Burriss, former division engineer in charge of flight test activities. New groups will have the responsibility of developing and interpreting MSD obligations under specific contracts as they are assigned.

NAA Consolidates Purchasing Office of Rocketdyne Division

Purchasing activities of North American Aviation's Rocketdyne Division have been consolidated under one roof with the recent shift of 600 employes into a new materials building in Canoga Park, Calif.

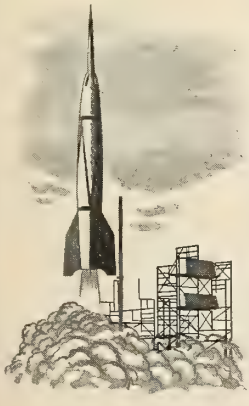
Division purchasing, which involves a $60 million annual volume, supports local production of the Rocketdyne Division and involves more than 3,000 suppliers in 34 states.

NAA Nets $9.8 Million For First Quarter

North American Aviation, Inc. reports a net income of $9,898,999 for its first quarter ended December 31, a $2.7 million increase over the same period in 1955. Sales and income for the period amounted to $330,526,940 compared to $195,935,978 a year ago.

NAA's net represented $1.23 as share against $0.89 in the first quarter of 1955. Federal income taxes were estimated at $10,722,000 for the three months based on preliminary figures.

Advances in Digital Telemetry Reported



A new system of handling information in direct digital form is opening a serious bottleneck in telemetry and said to be saving up to six months time

Being interviewed is Joseph Sullivan, Manager of the Silver Battery Division

"They're small in size, but they're for large missiles"

At the Exide Laboratories:—

Reporter: Do large missiles usually need a higher capacity battery?

Sullivan: Yes, because there are generally heavier loads to be energized.

Reporter: How do you get high capacity into such small sizes?

Sullivan: Well, we do it in this case with silver zinc rechargeable batteries.

Reporter: What are the advantages of silver zinc?

Sullivan: We find it combines the greatest reliability and output per unit of weight and volume of any type now in use.

Reporter: In what range of sizes do you make silver zinc missile batteries?

Sullivan: You're looking at four sizes rated at 5, 20, 40 and 60 ampere hours. We are also prepared to build batteries of any size from ½ to 150 ampere hours—or greater.

Reporter: You say these batteries are rechargeable. Do you also make so-called one-shot or primary batteries?

Sullivan: Yes. And the silver zinc primary batteries built by The Electric Storage Battery Company have hermetically sealed electrolyte systems that insure long shelf life.

Reporter: Then you offer a stock line of missile batteries?

Sullivan: We do. And in addition, we have the engineering staff and manufacturing facilities to design and build batteries to meet an unlimited variety of different requirements.

Note to missile manufacturers. When you buy batteries, be sure to get all the advantages available in Exide Batteries. For complete technical information, write Missiles Application Department of the Exide Industrial Division, The Electric Storage Battery Company, Phila. 2, Pa.

NEW

Trans-Sonics*

"TAPE-ON" SURFACE TEMPERATURE RESISTORS

for Temperature Telemetering

- NO THICKER THAN A PIECE OF TAPE
- OUTPUT UP TO 5 VOLTS WITHOUT AMPLIFICATION
- AVAILABLE IN VARIOUS RANGES FROM −300° to +400°F.
- RESISTANCE CHANGE OF 100 OHMS OVER SPECIFIED RANGE
- NO HOLES TO DRILL — QUICK AND EASY "TAPE-ON" INSTALLATION

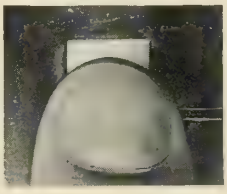
Trans-Sonics Type 1371 "Tape-on" Surface Temperature Resistors are precision resistance thermometers with a platinum resistance winding as the sensing element. These resistors which are no thicker than a piece of tape may be applied to *any surface* whose temperatures are to be measured. In a commutation circuit, they modulate standard telemetering transmitters without amplification. The new Type 1371 "Tape-on" Surface Temperature Resistors may be added to an installation using other Trans-Sonics temperature transducers without any further circuit modification. Each resistor is furnished with 6" long fibreglas-covered constantan leads. Write for Bulletin 1371 to Trans-Sonics, Inc., Dept. 9.

*Reg. Trademark

SPECIFICATIONS

SIZE: ¼" x 5/16"

Accuracy: ±2% of full scale range



Precision: ±0.5% of full scale range

Maximum Continuous Current: 20 ma rms (averaged over 1 second)

Environmental Operation Conditions
Vibration: 1" double amplitude, 0 to 22 cps ± 25g, 22 to 2000 cps

Shock: 100g in any direction, per paragraph 4.15.1 of MIL-E-5272A (10 milliseconds shock)

INSTANT INSTALLATION

As easy to apply as a thumb print.

For Transducers, See Trans-Sonics

Trans-Sonics, Inc.

P. O. BOX 328 LEXINGTON 73, MASSACHUSETTS

in the analysis of rocket and missile flight data.

A system developed by Radiation, Inc. for digital data computing receives information in direct digital form at a speed of 24,000 samples per second with an accuracy of one part in 256.

Two of the systems have been built and are in use by Wright Patterson AFB and Convair. Other systems are under development for AC Sparkplug, AVCO, Holloman ADC, Kirkland AFB and project *Vanguard*.

R-W Center Takes Shape

Ramo-Wooldridge Corp. has completed the first unit of a nine-building research and development center being built on a 41-acre site south of Los Angeles International Airport.

First building is assigned to the company's control system division, electronic instrumentation division, and two laboratories—one for aeronautical research and the other for electronics research.

Office and laboratory space in the first unit will accommodate about 500.

Douglas Investing $3 Million In New *Thor* Facilities

Douglas Aircraft Co. plans to spend up to $3 million over and above the $1,305,500 in funds supplied by the Air Force for construction of a guided missile facility in the Sacramento area this year.

F. W. Conant, senior vice president, said more than $2 million in contracts already have been let for land clearance at the 1,700 acre site, construction of roads, missile test stands, assembly and modification hangars.

Outstanding contracts also provide for a cafeteria, fire and plant protection building and control building.

The new Douglas facility will be used initially for development and test work on the Air Force's *Thor* IRBM.

Lockheed Talks Terms On Four New Missile Deals

Lockheed Missile Systems Division is negotiating four additional contracts, according to general manager L. Eugene Root. In a year-end review, Root said the division started 1956 with a dozen major contracts and a number of minor ones and added two very important new jobs and eight minor ones during the year.

Lockheed recently was named major contractor in the Navy's new *Polaris* fleet ballistic missile program;

missile division sales are running at about $60 million annually compared to $24 million a year ago and backlog has doubled in the last six months.

Missile Spending Reaches $1.5 Billion Annual Rate

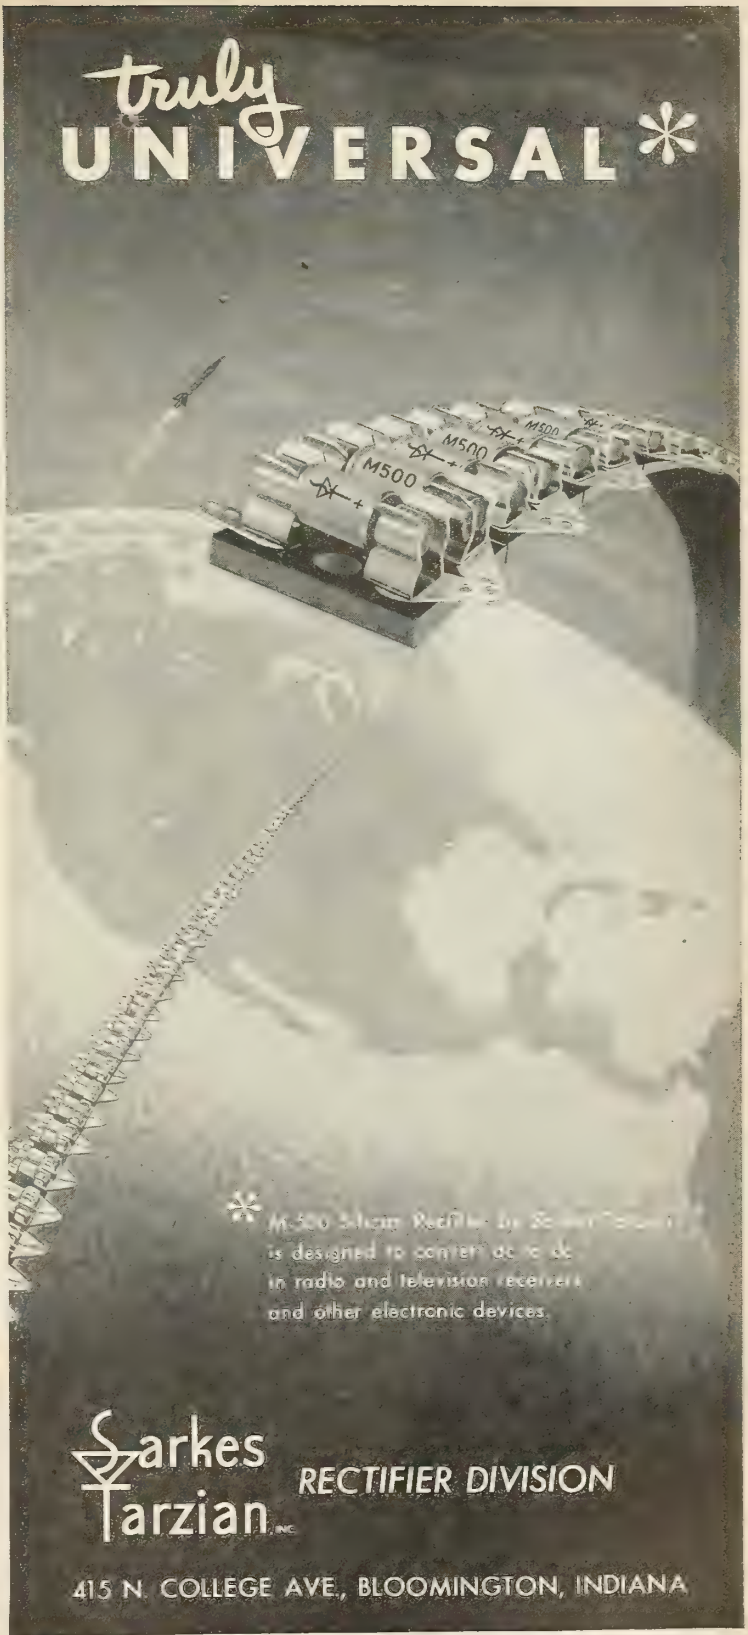
Total Defense spending by Army, Navy and Air Force for the first four months of fiscal 1957 reached $506,249,000 for an annual rate exceeding $1.5 billion. The unexpended balance as of October 30 stood at $3,828,245,000 with individual services reporting these accumulated spending figures for the four months:

Army	$116,977,000
Navy	67,851,000
USAF	321,421,000

New missile obligations for the period totaled $699,217,000 with this breakdown by service: Army—$86,289,000; Navy $134,029,000; and USAF—$478,899,000. Unobligated balance on October 30 for the three services was $1.98 billion.

RMI Income, Backlog Increase Sharply in '56

Preliminary 1956 year-end figures for Reaction Motors, Inc. show sales in excess of $15,500,000, an increase of nearly 50% over 1955. Company officials expect the final 1956 report to show a substantially higher net profit after taxes of at least $330,000.



RMI backlog on December 31 stood at $22 million, up about 150% over the same time in 1955. Employment was 1,350 compared to 669 at the beginning of 1956.

AF Awards 3 Contracts For Ballistic Missiles

Air Force has negotiated cost-plus fixed fee contracts totaling nearly $600 million with Douglas, Convair and Martin—prime contractors in the *Thor, Atlas* and *Titan* ballistic missile programs respectively.

Largest of the three, amounting to $358,000,000 went to Martin for design, fabrication and testing of the *Titan*. Award to Convair for similar activity on the *Atlas* was valued at $145,000,000. Douglas' contract for the *Thor* totaled $67,500,000.

Dollar values of the contracts, however, were labeled "rough estimates," not to be used as an index of the size of the three projects. The Martin contract, for example, covers a substantially longer period than that awarded Convair or Douglas.

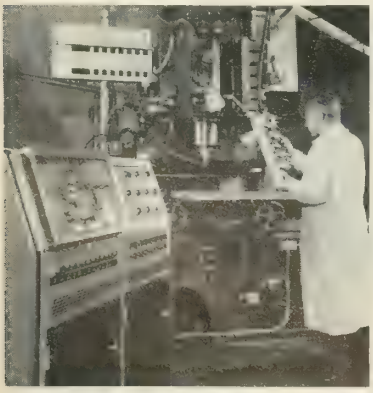
NEW MISSILE PRODUCTS

ROCKET FLIGHT SIMULATOR

A simulator for acceleration-sensitive devices used in rockets and missiles permits testing for acceleration and deceleration effects. A vector seeking specimen mount is used which eliminates nearly all undesirable side accelerations. An acoustic specimen cavity and special microphone permits audio data sensing of hermetically sealed units.



Two energy storing flywheels are used which can accelerate a device from 2 to 125 g in 200 milliseconds. Minimum braking time is 100 milliseconds. Maximum flight time is 55 seconds. A program unit controls acceleration-deceleration cycling through adjustable cam operated switches which control magnetic clutches and brakes. The Magnavox Co.

Circle No. 205 on Subscriber Service Card.

MACHINE CONTROL SYSTEM

North American Aviation's Autonetics Division has developed Numill, a tape control system designed big-machine automation to small lot and single part production of aircraft and missile tools and parts.

The system is adaptable to lathes, boring mills, contour mills and grinders

and permits finished tools or parts to be produced without use of blueprints. Sole guidance for machine operation is provided by instructions recorded by a standard electronic brain on magnetic tape and continuously monitored by automatic electronic gauges.

Basically, its operation hinges on the transfer of recorded instructions from the tape into electrical signals to direct the movement of the machine. An instruction panel specifies the materials and tools to be used.

Within a few years, North American officials predict, control systems like Numill will be in widescale use in by firms engaged in small lot production. Further, their use will provide the competitive advantages of improved parts uniformity, reduced costs and greatly shortened lead times.

North American Aviation, Inc., Autonetics Div., International Airport, Los Angeles 45, Calif.

Circle No. 207 on Subscriber Service Card

TEMPERATURE PROBE

A temperature probe for missiles and aircraft features very high recovery and negligible radiation and conduction errors for operation to temperatures of 1000° and 2800°F. For either boom or strut mounting, the T-1305 aircraft total temperature probe can be obtained with a choice of resistance or thermocouple elements. Resistance elements of wire wound type go to 1000°F and thermocouple types to 2800°F.

The units use the double stagnation principle and are said to have rapid response to temperature changes and complete insensitivity to 20 degree angle of attack. Aero Research Co.

Circle No. 204 on Subscriber Service Card.

PRESSURE TRANSMITTER

New Synchrotel pressure transmitters designed for use in high performance aircraft and guided missiles weigh about one pound, about one-third that of previous models, according to the manufacturer.

The Synchrotel transmitter are used for transducing pressure values as electrical signals. They are used with air and navigation data computers as well as flight and engine control systems where accurate measurement of pressure functions is a must and where space and weight are at a premium. Kollsman Instrument Corp.

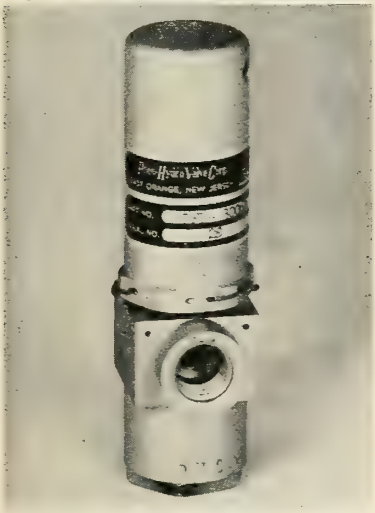
GYRO ROTOR ALLOY

New high-strength, high density alloy introduced by P. R. Mallory & Co. for use in gyro rotors is said to withstand rotor speeds about 25% higher than allowable with other materials.



A sintered alloy of tungsten, nickel, copper and other elements, Mallory 1000 Gyromet has a density of 16.70-17.05 grams per cubic centimeter. Proportional elastic limit is 62,000 psi and endurance limit 55,000 psi.

According to its producer, the new alloy has considerably higher stability and strength than previously obtainable, an indication of its potential use in inertial guidance systems where exceptional precision and uniformity are in demand. P. R. Mallory & Co.

Circle No. 212 on Subscriber Service Card

PRESSURE REDUCER

New series of lightweight pressure reducers designed to meet Spec. MIL-R-8572 range in weight from 0.4 to 0.6 lbs. and are intended for 3,000 psi aircraft and missile pneumatic systems. Units are available for ¼-in. and ⅜-in. tube sizes with larger models supplied on request.

Valve design includes built-in relief provisions, but reducer is available without this feature for special pneumatic or hydraulic system installations. Unit is balanced for straight-line regulation, leak-tight shut-off and small initial pressure drop. Operating temperature range is from —65°F to 225°F. Pneu-Hydro Valve Corp.

Circle No. 210 on Subscriber Service Card

TEMPERATURE SENSING RESISTORS

A new line of "Tape-On" surface temperature resistors that can be applied to any surface with a small piece of Mylar tape have been announced. Designed for temperature telemetering, the sensing elements have an output up to 5 volts and can be used directly in a commutation circuit to modulate standard telemetering transmitters.

Resistance change over the temperature range is 100 ohms. The resistors are available in various ranges from —300°F to +400°F. They have two 6" long fibreglass covered constantan leads.

Size is ¼" x 5/16". Accuracy is rated at ±2% of full scale range. Precision is ±0.5% of full scale range. Maximum continuous current is 20 ma rms (averaged over 1 second). Trans-Sonics, Inc.

Circle No. 216 on Subscriber Service Card

SEALED SWITCHES

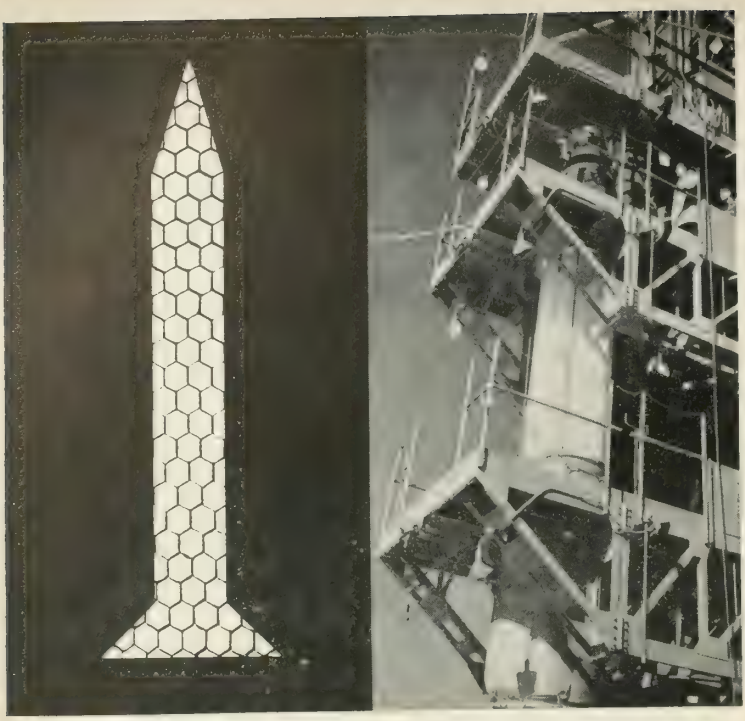
New hermetically-sealed, potted switches for aircraft and missile use feature a threaded actuator plunger guide for versatility of mounting. This arrangement permits location of switch actuator button flush with mounting board or at any extended distance up to ⅞ in.

Model No. 9129, when mounted on actuator, has ⅛ in. overtravel with equal pretravel along the plunger. Tests by manufacturer indicate units conform to MIL Spec. 50-g shock limits.

Actuator button is compounded from special elastomers said to flex satisfactorily at —90°F and at 285°F. Switch is bonded to switchover and is rated to withstand 100 psi pressure differential inside to outside without rupture or leakage. Literature available. Haydon Switch, Inc.

Circle No. 211 on Subscriber Service Card

METAL LAMINATES



A new series of metal laminates employing a true metallurgical bond in combinations of two or three metals have been unveiled by Bridgeport Brass Co. Combinations include stainless and mild steels, Monel, copper, brass and titanium plus some precious metals bonded to form laminates or sandwich structure of varying thicknesses.

Advanced research is being continued on the use of the laminates in nuclear power and missile applications. Bridgeport Brass Co.

THE HIGH LEVEL OUTLOOK

FOR STRUCTURES ENGINEERING

Martin is *now at work* on the structural problems of flight vehicles ranging upward in speed from Mach 2 to 25,000 feet per second!

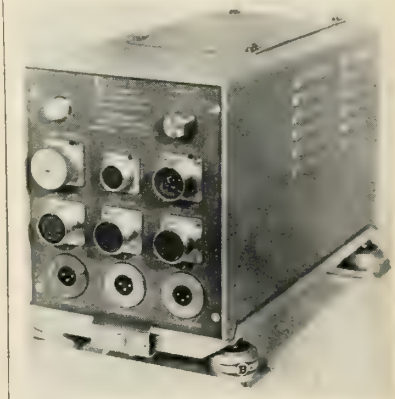
These are the speed factors of two actual projects now being developed at Martin. If you are interested in tomorrow's problems of structural layout ...stress analysis...vibration and flutter...multi-Mach heat resistance... and the most advanced work in structures testing, with the finest testing facilities in the world:

Contact J. M. Hollyday, Dept. MR-2, The Glenn L. Martin Company, Baltimore 3, Maryland.

MARTIN
BALTIMORE

PRESSURE SWITCH

High temperature pressure switch rated for operation at 650°F in airframe, missile and rocket systems weighs only 11 oz. Unit uses all-welded stainless steel



construction, an advanced type of snap-action switch element and a precision stacked-capsule sensing element, according to its producer.

The pressure switch is usable in standard aircraft fluid systems, air and hydraulic systems. Absolute-pressure version provides an adjustment range of 20 to 75 psia with a reset value, or difference between make and break, of 2 psi.

The Type 6576 switch adjustment is externally accessible through the inlet port. Rated proof pressure is 100 psi and burst pressure 150 psi. Contacts are SPST or SPDT rated at 1 amp. inductive. Overall dimensions are 1 1/ in. diameter by 3¼ in. long. Manning, Maxwell & Moore, Inc.

⅔ actual size

Honeywell Aero's MIG (Miniature Integrating Gyro) represents a scientific breakthrough in floated gyro design. Only 1.75 inches in diameter, and weighing less than 0.5 lb., its performance compares to hermetic integrating gyros three times larger. Primarily used in stable platforms, the MIG excels in short-time inertial and aided-inertial applications. Such miniaturized components typify Honeywell Aero's anticipation of advanced flight control system needs.

AERONAUTICAL DIVISION, MINNEAPOLIS-HONEYWELL

Firm footing for tomorrow's airborne instruments...

Not just another new plant for the aircraft or electronics field, but the *planned result* of a pioneer in the field of instrumentation and aircraft accessories.

Adding new engineering design and development facilities to long experience and top personnel, Pacific will continue to originate products which are a significant step ahead of the field.

Whether you rely on Pacific for such proved designs as the rugged rate gyros and accelerometers shown below, or for undreamed of instruments to solve future problems, Pacific is always ready and anxious to serve you.

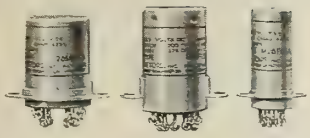
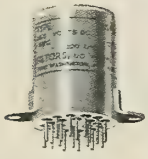
POTENTIOMETER

A high performance potentiometer for severe environmental applications has a resistance of 30,000 ohms ±10% and withstands temperatures from —65°F to —275°F, 10g vibration from 10 to 1500 cps, and shock to 60g.

Model RP04-0101 weighs 2.5 oz. Distance travel is 4.13 in. Service life is 1,000,000 cycles. For mechanical positioning, the case and actuator have a vernier scale reading to 0.010 inch increments. Humphrey, Inc.



Circle No. 202 on Subscriber Service Card.



FREQUENCY DETECTOR

Narrow band frequency detector for telemetry and instrumentation applications provides an output current linearly proportional to frequency within a band width of 375 to 425 cycles. Units can also be provided to cover 10% bandwidth at any center frequency from 30 cps to 5 kc.

Output is suitable for operating a d'Arsonval instrument, servo-type recorder or a control curcuit. Linearity is within ¼% of midband frequency. Detector is hermetically sealed; operates from —55°C to 72°C; withstands 10g vibrations to 2000 cps and shocks of 30g in any direc-

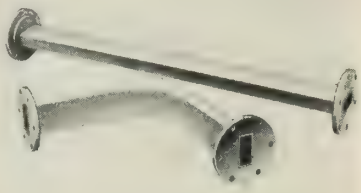
INPUT-OUTPUT TYPEWRITER

A new electric IBM typewriter designed for use as an input and output unit for the data processing field has been announced. It can be used in conjunction with measuring and recording instruments, scales and meters for engine resting, liquid flow measurement and wind tunnel research to provide a visual record.

Electro magnets and solenoids act as receivers of signals from a controlling device or computer to actuate the keyboard. Typing is done at the rate of 120 words per minute. Actuated functions include carriage return, spacing, tabulation, ribbon color control and others.



As an input device electrical impulses are transmitted by depressing the typewriter keys. International Business Machines Corp.

HIGH-CONDUCTIVITY WAVEGUIDE

Oxygen-free high/conductivity copper is used in Airtron's waveguide components to minimize losses in long transmission lines. Now available are components such as straight sections, circular bends and adapters in the new material for WR-137 waveguide size.

For microwave relay systems operating in the 6000 mc region, the waveguide components of the new material have general application in indoor and outdoor cabinet applications since the high conductivity gives a lower insertion transmission loss for extended waveguide runs in these applications. Attenuation is between 2.0 and 2.4 db/100 ft. Airtron, Inc.

Circle No. 203 on Subscriber Service Card.

HIGH OUTPUT TRANSDUCERS

Resistance-type temperature transducers that give outputs up to 5 volts in telemetering and other applications are available in a variety of configurations for measurement of surface, fluid, and air temperatures.

Units cover temperature ranges of —320°F to 500°F with linearity rated at ±2%. Special units are available that cover up to 1600°F. Resistance values are 100 to 20,000 ohms. Either ac or dc bridge circuits may be used.

Each probe is supplied with a serialized calibration curve. Units are stated to meet MIL-5272 specification. Arnoux Corp.

Circle No. 214 on Subscriber Service Card

AMPLIFIER KLYSTRON

An amplifier klystron for use as the final amplifier of a high power microwave transmitter permits amplification of frequency, amplitude or phase modulated signals at power gains of about 50db. Featuring all-ceramic and metal construction, the VA-806 provides 2000 watts of continuous power in the 7125 to 8500 mc range.

The tube is water cooled and has a four cavity amplifier section tunable ±25 mc from specified center frequency. It features matched waveguide input and output, and low FM and AM noise. Varian Associates.

Circle No. 201 on Subscriber Service Card.

MISSILE MATERIAL

The Russell Manufacturing Co. has developed a new high temperature resistant Rusco woven material for rocket and missile parts insulation that is said to have stable performance characteristics under temperatures ranging up to 2,000°F.

Company reports it has developed techniques for weaving a ceramic fibre into tapes, sleeves, tubes and almost any other shape that might be required to meet particular applications.

HOLSCHUH

Carl G. Holschuh has been appointed president and gen. mgr. of Sperry Gyroscope Div., Sperry Rand Corp., succeeding **Charles M. Green,** retiring. **Mr. Holschuh** steps up from exec. vice president and gen. mgr.

Elmore P. Pillsbury, formerly chief of aeromechanical engineering for Fairchild Guided Missiles Division, Fairchild Engine and Airplane Corp., has been appointed chief engineer for the division.

Raymond J. Condon, mgr. of military sales for Minneapolis-Honeywell Regulator Co.'s Aeronautical Div., has been appointed vice president-government projects for the division.

Charles H. Godschall, manager of tooling and tooling engineering for the Government and Industrial Division of Philco Corp., was presented the Distinguished Service Award, the Navy's highest civilian award, "for outstanding work in the development of a new underwater weapon."

Capt. F. D. Pfotenhauer (USN, ret.) was appointed vice president of production and **D. C. Eaton** was promoted to vice president of program management for Reaction Motors, Inc.

James D. McLean succeeds **John B. Moss** as president of Hoffman Laboratories, Inc. **Moss** becomes chairman of the executive committee and remains a director of Hoffman Electronics Corp.

Glenn D. Maxwell was appointed asst. director of Consolidated Electrodynamics Corp.'s advanced electronic data laboratory, and **Lenard Johnson** was named supervisor, laboratory services.

William R. Whittaker, president of Wm. R. Whittaker Co., Ltd., has been elected chairman of the board of Telecomputing Corp.

Max M. Tall was appointed head of the reliability program for missile control projects at Radio Corporation of America's Missile and Surface Radar Dept.

PEARSON

John E. Lowe, formerly personnel manager for American Machine & Foundry Co.'s electronics division, has been appointed director of personnel and public relations of the new guided missile launching system plant in Rochester. **Robert W. Pearson,** manager of reliability control in the Missile and Surface Radar Dept., Moorestown, N.J., has been appointed deputy general manager for operations of the electronics div. in Boston.

Dr. Clarence Zener has been named director of Westinghouse Research Laboratories, after five years as associate director and a year as acting director.

Henry M. Haase was elected president and chief executive officer of the York Division of Borg-Warner Corp. at York, Pa. **Stewart E. Lauer** became chairman of the Board.

Bell Aircraft Corporation's Research Division announced the following appointments: **John F. Hawkins,** administrative mgr.; **Robert E. Hannel,** services mgr.; **William Shultz,** sales mgr.; and **Ronald E. Shainin,** contract administration mgr. The Avionics Division made these appointments: **Frank H. Andrix,** director of engineering; **Joseph D. Schantz,** assistant to division mgr.; **Robert C. Sellers,** sales mgr.; **Howard H. Herod,** contract administrator.

Maj. Gen. Francis H. Lanahan (USA, ret.) has been elected president of the Federal Electric Corp., subsidiary of International Telephone and Telegraph Corp.

Dr. C. B. Jolliffe, vice president and technical director of Radio Corp. of America, will head the new Special Systems and Development Dept. Other appointees are: **A. W. Vance,** chief systems engineer; **G. L. Dimmick,** chief development engineer; **A. C. Gay,** mgr., projects engineering; and **Dr. E. W. Pritchard,** administrative engineer.

Lewis F. Millett has been named to head radar development department of Bendix Aviation Corp.'s Research Laboratories division.

E. L. Rucks, principal engineer for Aerojet-General Corp., will head the new structural plastics group of its Solid Engine Division, whose principal activities are in the field of pressure vessels, thermal insulation and components for rockets and missiles.

LOWE

RESEARCH ENGINEERS

Challenging positions are available in research and development for men with B.S. to Ph.D. degrees in Physics or Mechanical Engineering and experience or interest in the fields of rocket propulsion, ballistics, and ordnance.

We offer you an opportunity to use your initiative and creative ability in an atmosphere conducive to accomplishment. These positions afford association with some of the leading engineers in this field.

Excellent employee benefits including tuition free graduate study. Please send resume to:

Two hundred reporters, many from Europe and Latin America will learn about IGY and the Vanguard satellite program. Top left to right: Paddy Kavanagh, CANADIAN AIR REVIEW; Ed Kirschner, free lance, U.S.; Erik Bergaust, MISSILES & ROCKETS; James Cunningham, United Press. Bottom, left to right: Sydney Cooper, International Civil Aviation Organization, Montreal; Anthony Vandyk, AMERICAN AVIATION and MISSILES & ROCKETS; Ross Willmot, Executive Secretary, ISAW, Toronto. International aviation writers will set up headquarters at the Roosevelt Hotel in Washington. They will attend the American Rocket Society sessions to take place April 3-6. President of ISAW is Arthur Riley, Aviation Editor of the BOSTON GLOBE. ISAW was formed in San Francisco last year. It now has more than 300 members; more than 100 accredited US aviation reporters have joined.

•

Wanted!

Engineers to sign on for one of the most exciting scientific expeditions of our time:

The SM-64 Navaho Missile

The men behind this invitation are pioneers in missile development. Ten years ago they started from scratch. There were no texts to consult, no rules to follow. Today their technological achievements are so great ... their jobs so broad ... there is room at every level of engineering for additional mindpower.

Accept this challenge and you can travel faster and farther than you ever thought possible on one of the most important programs in the free world today—North American's complete weapons system responsibility for the Air Force SM-64 Navaho Intercontinental Strategic Guided Missile.

DOUGLAS K. BAILEY received his BS degree from the University of California. He joined North American ten years ago as a senior design engineer. Today he is chief, Missile Design Section—responsible for missile design engineering and analysis. Doug and his family live in Long Beach where he participates in golf, bowling and sports car activities. He is currently organizing road races in Southern California for the Long Beach MG Club.

Unprecedented programs have been completed and more are to come. Others are being developed, modified and perfected as we enter another exciting phase following a successful flight test program at Patrick Air Force Base using a test vehicle known as the X-10.

The fascinating nature of this work has already attracted the world's best informed missile men. Top-tier men have opportunities in almost every field of engineering—including some of the most advanced work being done today in aerodynamics, thermodynamics, high temperature materials and aero-elasticity.

Solving these problems is bringing forth new formulae and new production techniques. One example is Chem Mill, the process of shaping metals—including titanium and newest alloys—to previously unattainable designs by chemical etching. This method reduces weight ... increases strength. The idea came from a North American Missile engineer.

Navy vet **GEORGE W. JEFFS** earned both his BSAE and MSAE from the University of Washington. About 9 years ago he started his professional career with North American as a junior aerodynamics engineer. Now, 5 promotions later, this 30-year old veteran of missile work is chief, Advanced Design Section. He lives in Downey, California with his wife and 3 children. His hobbies include fresh-water fishing and hunting for quail and pheasant.

This is the kind of opportunity open to you. You can share our knowledge and add to it.

Recent graduate engineers can step into established groups. Experienced men will find even greater opportunities in the new groups that are being formed. And you'll do this in a management climate that stimulates personal growth and rewards it with responsibility, professional recognition and material benefits. Further, you can continue your studies with the aid of North American's Educational Refund Plan ... live and work in Southern California ... in near-ideal climate.

Let us know what kind of creative engineering interests you. (Please include highlights of your education and experience.)

Write today to: Mr. R. L. Cunningham, Engineering Personnel Manager, Dept. 91-2-MAR
Missile Development Division, 12214 Lakewood Blvd., Downey, California.

NORTH AMERICAN AVIATION, INC.

High-speed control for high-speed missiles

Nowadays, target, aircraft, and missile speeds are too fast for human reactions. Automatic equipment makes ready, radar eyes take aim and a computer pulls the trigger.

Replacing men with machines on the firing line gives us a better chance for an interceptor kill or successful missile shot. And, today, we can't afford to miss. That's why reliability of every component is so important in modern fire control gear. And reliability is the main reason engineers—like those designing Northrop Aircraft's Snark missile (above)—so often pick Bristol's® Syncroverter® High-Speed relays (or the very similar Syncroverter chopper).

These high-speed relays have a normal life of billions of operations in dry circuit applications. They're available in SPDT and DPDT models with the typical characteristics listed below and in many variations.

And, of course, many critical applications other than fire control—such as air-to-ground telemetering, analog and digital computers, aircraft or missile navigation equipment, carrier current switching—can benefit from the outstanding reliability of Bristol's Syncroverter line. Write for complete technical data today. The Bristol Company, 173 Bristol Road, Waterbury 20, Conn. 6.61

TYPICAL CHARACTERISTICS

Temperature range: —55°C to 100°C
Operating shock: 30G; 11 milliseconds duration
Vibration: 10-55 cps (see below, Mounting); 10 G
Contact ratings: up to 35v, 45 microamperes
Stray contact capacitance: less than 15 mmfd
Pull-in time (including bounce): as low as 200 microseconds
Drop-out time: 300 microseconds
Life: Billions of operations
Mounting: Octal tube socket; others available, including types for vibration to 2000 cps.

BRISTOL FINE PRECISION INSTRUMENTS FOR OVER 67 YEARS

Circle No. 26 on Subscriber Service Card.

missile literature

ACID RESISTANT COATINGS. The Development of a Protective Coating Resistant to Nitric Acid and Hydrocarbons; by D. F. Siddall, E. Hillier, R. Garling and M. Gunther of U. S. Stoneware Co. for WADC; 116 pages; $3.00. Order Ref. No. PB 121217S. Review of research program to prove out X-200 resin or Kel-F 800 as a fluorinated material resistant to white fuming nitric acid encountered in acid tanks and assisted takeoff compartments of jet aircraft.

EXPLOSIVE VAPOR DETECTION. Study of Explosive Vapor Detection; by T. M. Shaw, F. K. Truby and W. R. Wood, Southwest Research Institute for WADC; 277 pages; $6.00. Order Ref. No. PB 121517. Report reviews results of survey of vapor detection methods and instrumentation with conclusion that no completely satisfactory principle of operation or sufficiently compact instrumentation exists for vapor detection in rocket-propelled aircraft. Recommendations are offered on possible methods of detecting fuel and oxidizer vapors, optimum detection methods and use of tracers.

HIGH TEMPERATURE MATERIALS. Cemented Borides; by American Electro Metal Corp. for Office of Naval Research; 140 pages; $3.50. Order Ref. No. PB 121346. A summary of experiments with Barolite IV, a promising high temperature material comprising several compositions of a chromium boride, Cr_2B and a Cr-Mo alloy. It is said to possess outstanding heat shock resistance, oxidation resistance and stress-to-rupture strength through 2,000°F.

TITANIUM CARBIDE. Iron Bonded Titanium Carbide, by R. E. Wilson, New York State College of Ceramics; for WADC; 39 pages; $1.00. Order Ref. No. PB 121323. Report describes techniques developed for hot pressing iron bonded titanium carbide into various shapes to enable determination of its physical properties. Although material was found inferior to nickel-bonded titanium carbide for use in aircraft power plants, extensive work with hot pressing is reported to have advanced that art. Iron-titanium carbide was effectively hot pressed with either the carbide or the metal as the continuous phase, depending on temperature used in the process. Also, molybdenum disulfide suspended in ethylene was found effective as a parting medium in hot pressing.

TITAIUM CLADDING. Roll cladding of base metals with Titanium, by P. T. Mataich and F. C. Wagner, Horizons, Inc.; for WADC; 36 pages; $1.00. Order Ref. No. PB 121479. Describes experiments with roll cladding of titanium to steel using a number of different metals as bonding agents. Best bond was obtained with a chromium plated layer on steel which was pressure-welded to titanium, but good bonds were also obtained by plating successive layers of silver and nickel on the titanium before cladding. Elements such as cobalt or nickel formed strong bonds to titanium—but in a very limited temperature range—a restriction which would make commercial work difficult, the report states. Although study indicated roll cladding is possible on a laboratory basis, the use of alloys as bonding agents is believed a possible means of producing higher strength bonds and further research is recommended.

DATA REDUCTION. Automatic Data Reduction—Part II, by R. S. Hollitch and A. K. Hawkes, Armour Research Foundation; for WADC; 80 pages; $2.00. Order Ref. No. PB 111928. A catalog of devices useful in automatic data reduction listing five categories of such devices commercially available or under development. Scope of listing is limited to equipment that is digital in nature. Categories include analog voltage to digital converters; shaft position to digital converters; digital plotters and digital to analog converters; miscellaneous digital devices; and, special tape recorders. An appendix lists producers of the devices.

DATA STORAGE: Superimposed Coding for Data Storage; by M. Taube, Documentation, Inc. for Office of Naval Research; 27 pages; $0.75. Order Ref. No. PB 121345. Report discusses methods of superimposing coding, or the recording of two or more codes in the same field, to facilitate information searching on machine sorted index cards.

ENVIRONMENTAL TESTING. Correlation of Natural Weathering and Sheltered Storage Exposure Tests with Simulated Environmental Laboratory Tests, by W. E. Laesch and W. W. Smith, South Florida Test Service; for WADC; 60 pages; $1.50. Order Ref. No. PB 121321. Report of investigation of the possible correlation between natural and laboratory-simulated weathering and storage tests on degradation of metals and plastics. Results showed no significant correlation between the simulated environmental tests and data obtained from natural weathering tests of the metals, or of lucite and laminated phenolics.

The Defense that Research Built

Working closely with various government agencies and aviation companies*, The M. W. Kellogg Company has participated in many important research and development phases of the rocket program. This has covered a wide range of missiles and rocket propulsion systems for Terrier, Talos, Snark, Sparrow, and Nike. Kellogg has also produced booster rocket cases and other components.

M. W. Kellogg's long rocket experience, supplemented by this organization's 50-year background of engineering and fabricating high temperature-high pressure industrial products, continues to provide valuable assistance to National Defense.

*Including the Navy, Army, Air Force, Allegany Ballistics Laboratory, The Johns Hopkins University Applied Physics Laboratory, and such well-known aviation names as Bell, Boeing, Convair, Douglas, Grumman, Lockheed, McDonnell, Northrop, Republic.

industry briefs

THIOKOL CHEMICAL CORP. has received six new rocket engine development contracts from Army's Redstone Arsenal. Largest is valued at $442,743 for continued development of propulsion system for Raytheon *Hawk* I. Others involve XM19, XM19E1 and XM20 rocket engines ($329,180); *Lacrosse* rocket engine ($325,328); M58-E4 engine for Hughes *Falcon* ($41,-482); and continued R&D on large propellant type engines ($386,935).

BELL AIRCRAFT CORP. has been awarded two additional Air Force contracts totaling $22,040,047 for further R&D work on *Rascal* air-to-ground missiles.

BOEING AIRPLANE CO. has abandoned plans for a separate, fully-integrated guided missile division it hoped to establish near Richmond, Calif. Option on Ford Motor Co. plant there has been allowed to lapse and two additional options on local acreage will not be exercised. Reason: Air Force refused to support Boeing's plan for new division, hence *Bomarc* missile production will revert to company's Seattle plant with support from Wichita division and subcontracting firms.

McDONNELL AIRCRAFT CORP. reports earnings of $3,862,453 for first half of its fiscal year ended December

31 compared to $2,663,902 a year ago. December 31 backlog stood at $831,171,849 compared with $607,468,294 last year. Company is a key producer in *Talos* and *Green Quail* missile programs.

THREAT OF PROLONGED WORK STOPPAGE at Patrick AFB Missile Test Center ended abruptly February 1 when some 600 of 900 non-union workers striking against Pan American World Airways returned to work after one-day walkout. Their demand for vote on union affiliation remained unsettled at presstime.

AEROPHYSICS DEVELOPMENT CORP., Curtiss-Wright Corp. subsidiary which developed the *Dart* missile and HTV (hpersonic test vehicle), expects to occupy the first two of five proposed new buildings on February 15.

HUGHES AIRCRAFT CO. plans construction of a new $6-million plant for production of ground radar system components on a 475-acre plot near Fullerton, Calif. Hughes expects to employ about 2,000 workers there by 1958.

HALLAMORE ELECTRONICS division of Siegler Corp. has received an addition to an earlier contract with Convair's Astronautics division for system design, fabrication and assembly of equipment used in Convair's missile program.

AN UNUSUAL BUY!

SATELLITE TELESCOPE

Edmund Scientific Co. was consulted by the coordinator of Visual Satellite Observations of the Smithsonian Astro-Physical Observatory regarding development of an optical instrument to meet the unique requirements of MOONWATCH. Needed was a low-cost instrument of greatest possible field—with the ability to observe faint objects with only slight magnification. Result—our Edscorp Satellite Telescope! Features: Wide (51mm) diameter, low reflection coated objective lens. 6 elements, extremely wide field, coated Erfle Eyepiece which, in combination with the objective, gives 5.5 power with a big 12 degree field and over 7mm exit pupil.

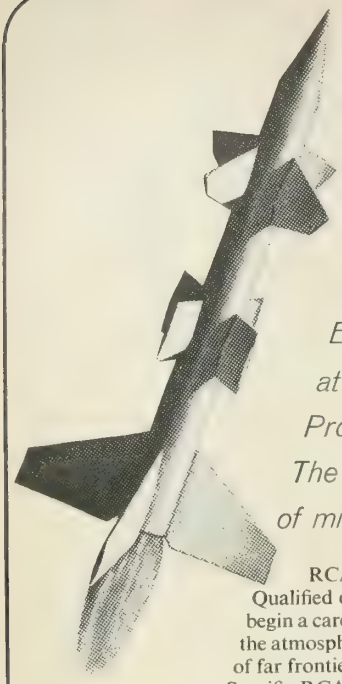
Flight Test Operations

for ICBM and IRBM

Technical Staff and Project Engineering opportunities are open on the R-W Staff at the Air Force Missile Test Center, Florida.



Ballistic missile test operations for ICBM and IRBM will explore new frontiers of missile flight. Providing technical direction in connection with these test programs is a significant aspect of R-W's systems engineering responsibility for these Air Force missiles.

The scope of R-W's assignment requires a Flight Test Staff of unusual breadth. Applicable technical fields include: geophysics . . . missile aerodynamics . . . propulsion . . . electronic and optical tracking systems . . . radio and inertial guidance . . . test data reduction and analysis . . . instrumentation systems . . . and ground support systems.

Please address inquiries to: Mr. W. J. Coster

The Ramo-Wooldridge Corporation

ELECTRONIC ENGINEERS...

become one of the first staff members of RCA's new ENGINEERING OPERATION at WHITE SANDS Proving Ground. The very nerve center of missile electronics!

RCA is new to White Sands! Qualified electronic engineers can now begin a career in a responsible position where the atmosphere crackles with the stimulation of far frontiers in missile electronics. Specific RCA assignments are in missile electronics, ground support systems, missile guidance and complex launching systems. You must, of course, have your EE, ME or physics degree, several years' electronic design experience . . . and must be familiar with one of these fields:

System and sub-system analysis
Reliability data control
Evaluation of new components
Internal instrumentation
Equipment control
Data analysis

Projects will relate to sub-systems such as:

PRECISION RADARS
DIGITAL DEVICES
ANALOG DEVICES
DATA PROCESSING EQUIPMENT
FIRE CONTROL
DATA SIMULATION

Start at an excellent salary . . . A full program of liberal benefits gives your income added security. RCA's Tuition Refund Plan will provide for advanced studies. RCA pays relocation expenses.

Bomarc Test Personnel Get Pay Increase

Boeing Airplane Co. and International Association of Machinists-Local 2061 have agreed on hourly wage increases from 14½¢ to 20¢ for employes assigned to *Bomarc* missile test facilities at Cocoa, Fla.

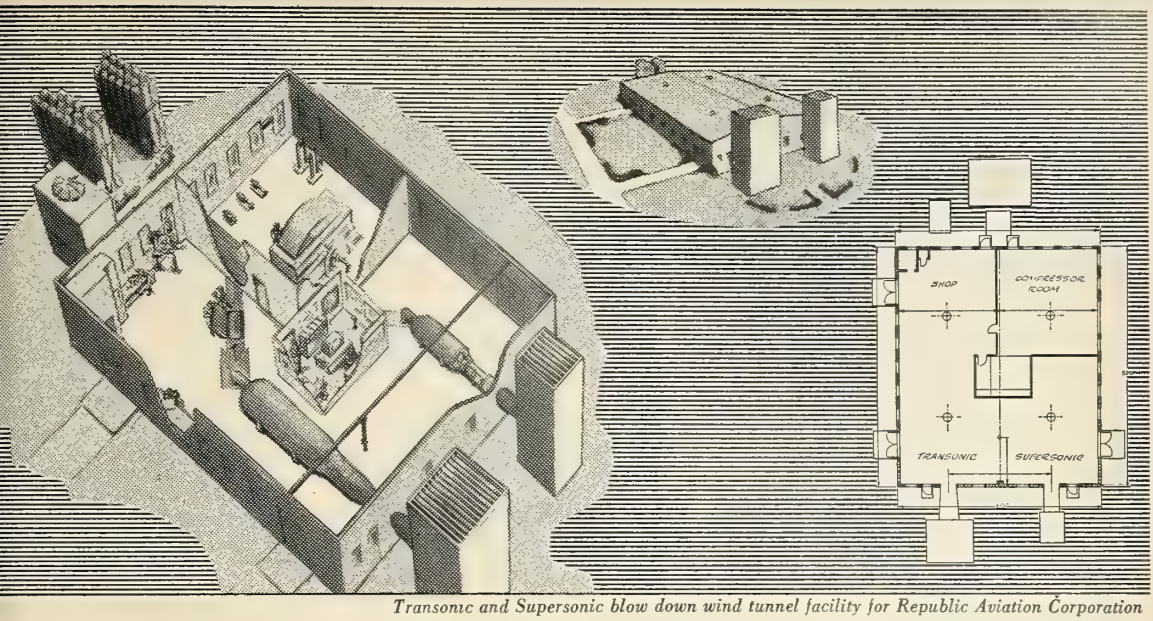
The agreement covers workers who service and test missiles built in Seattle. The increases raise the rates of employes in Labor Grade A to $2.80 an hour.

NAA Missile Workers Get New Recreation Center

A new 6700-sq. ft. recreation center at North American Aviation's Downey, Calif. plant was opened recently for use by personnel of company's Autonetics and Missile Development divisions.

New Center includes a 375-person capacity auditorium, two club meeting rooms, office, kitchen, lobby and rest rooms.

Douglas Plans Conferences To Aid Engineering Force



Douglas Aircraft Co. has held the first of a series of periodic inter-division conferences of design engineers —a meeting of chief aerodynamicists from five Douglas divisions.

The sessions, spearheaded by v.-p. engineering Arthur E. Raymond, are intended to take full advantage, throughout the Douglas engineering organization, of the diversified experiences at each of its divisions. In this way, Raymond feels, the overall Douglas engineering organization will be strengthened and improved.

On hand for the first session held recently in Tulsa, Okla. were O. E. Bottorff, asst. to Raymond, and these head aerodynamicists from Douglas divisions: W. B. Oswald—Santa Monica; K. E. Van Every—El Segundo; A. S. Church—Long Beach; H. F. Klecker—Tulsa and H. J. Gunkel—Missiles division.

GE Forms New Lab For Missile Research

General Electric Co. has formed a new Aerosciences Laboratory within its Missile and Ordnance Systems Department in Philadelphia. Its purpose: to conduct or direct applied research in specific fields of technology so that major improvements in missile weapons systems may be developed.

Transonic and Supersonic blow down wind tunnel facility for Republic Aviation Corporation

a special message to wind tunnel engineers and scientists

ANNOUNCING UNUSUAL OPPORTUNITIES WITH REPUBLIC'S NEW WIND TUNNELS SECTION OF THE R & D DIVISION

A new wind tunnel installation doesn't open every day!

Yet, that's exactly what's happening at Republic Aviation. A brand-new installation is being planned for Farmingdale, Long Island, dedicated to the study of all the complex, interrelated aspects of passage through the upper atmosphere.

What can this mean to you?

If you're presently a Director or Assistant Director of a wind tunnel installation, it means an opportunity to change pace —to express your ideas—and then implement them—in brand new facilities. And at the same time, to broaden your professional horizons.

Or perhaps you're a member of the operating staff at a wind tunnel. You've got experience, ability, intelligence. But you'd like a chance to get in on the ground floor of a new operation, with the most modern facilities at your command... and increase your opportunities from the very start.

If you're in any of these categories, you owe it to yourself—and your family—to check the following requirements and then contact us.

DIRECTOR: Should have 10 to 15 years' experience in the design, construction and operation of wind tunnels and related facilities, as well as complete staff administration.

STAFF: Preference will be given to people with direct or related experience, at all levels, in wind tunnel

PLANNING • PROGRAMMING • TEST OPERATION
ANALYSIS • INSTRUMENTATION

Republic engineers and scientists enjoy top-of-industry pay scales plus added financial and professional recognition for individual contributions. Benefits include our famous 2-Fold Retirement Income Plan. Educational Aid, and broad Life, Accident and Health Insurance Program. Unequalled Long Island Living, with all the cultural, educational and entertainment facilities of New York just minutes away.

Please send complete resume, in strictest confidence, to:
Mr. George Hickman, Engineering Employment Manager

Today it's rockets for the big in-at-the-crucial growth period opportunities ... don't let YOUR big chance get away ... get in touch with RMI now.

1957 YEAR OF OPPORTUNITY IN ROCKETS

The BIG careers in America's next BIG industry now being launched at Reaction Motors

The *time* to get into rockets is now. This young industry is becoming a giant overnight, thanks to developments that are pushing the field ahead faster than any other open to engineers and scientists today. 1957 will see significant advances that will bring the conquest of outer space closer to reality. Scientists and engineers who get into rockets this year with Reaction Motors will be strategically placed to rise to prominence in the industry ... for RMI is the oldest company in the field, a leader for 15 years, now embarking on a new, major expansion program involving every area of activity.

Whether or not you have worked in the rocket field before, there are high-calibre openings for you with Reaction Motors. Practically all basic professional knowledge and training is employed in rocket engine development and RMI's experts will help you acquire the specific know-how you need for an accelerating career in this burgeoning field.

Engineers and Scientists From 16 Fields Qualify for High-Calibre Positions in Reaction Motors' Expanding Program

Experience in any of these areas...

- Rotating machinery
- Instrumentation recorders
- Braking systems
- Stress analysis
- Air conditioning
- Numerical analysis
- Heat transfer equipment
- Fuel injection systems
- Metallurgy (high alloys, temp.)
- Jet or reciprocating engine design, test
- Pressure equipment, vessels, high vacuum
- Controls (hydraulic, pneumatic, electrical)
- Regulators (valves, hydraulic, pneumatic)
- Physics — solid state, atomic, etc.
- Chemistry — fuel, rubber
- Ignition systems

... is your passport to important assignments in one or more of these areas

- Engine design
- Chemical kinetics
- Combustion phenomena
- Servo mechanisms
- Project engineering
- Controls (hydraulic, pneumatic, electrical)
- Instrumentation
- Applications engineering
- Analog simulation
- Proposals
- Test
- Aerodynamics
- Fluid Flow
- Nuclear applications
- Data reduction
- High temperature
- Alloys
- Thermostress and vibration
- Technical planning (advanced design)
- Tool design

You will be working in the forefront of one or more of our 6 main Project Areas: Missiles • Piloted Aircraft • Launching Devices • Ground Support Equipment • Liquid and Solid Propellant Chemistry • Nuclear Rockets.

For further details drop a line or send complete resume — including address and phone number — in strict confidence to: Supervisor of Technical Placement, Reaction Motors, Inc., 50 Ford Road, Denville, N. J.

BENDIX OFFERS THE FINEST GUIDED MISSILE OPPORTUNITIES IN THE MIDDLE WEST

It isn't often that you can combine ideal living conditions with outstanding advancement opportunities. At Bendix Guided Missiles we sincerely believe we can offer you both.

We are sure that you would enjoy living in an attractive community convenient to metropolitan centers and recreational areas.

And, we are equally confident that as prime contractor for the important and successful Talos Missile, no one can offer a greater variety of interesting and challenging job opportunities in the guided missile field.

If you would like proof of these strong statements, why not fill out the coupon and send for a copy of our thirty-six-page booklet "Your Future in Guided Missiles". It not only gives a detailed story of guided missile operations, but it also presents interesting facts about living conditions in the area, the many special employee benefits, and the wide range of specific job opportunities we have to offer.

Send for your copy of "Your Future in Guided Missiles" today.

Bendix — prime contractor for the TALOS MISSILE

More C/L Wage Hikes Paid Aircraft/Missile Workers

Cost of living wage increases totaling 6¢ an hour are being paid to aircraft and missile production workers in two west coast plants as the result of the BLS 118.0 index for December 15.

At Douglas, hourly workers will get a 2¢ increase added to the 4¢ received in past C/L allowances. Northrop Aircraft, Inc., producer of the *Snark*, reinstituted the cost-of-living allowance in December and is paying 6¢ in a single raise.

North American Aviation paid an additional 2¢ C/L adjustment late last month based on the November 15 index bringing its total C/L allowance to 5¢ an hour.

In addition to these immediate changes, deferred wage hikes negotiated in a number of two-year labor contracts will soon go into effect. At Lockheed, which recently received the Navy's *Polaris* missile prime contract, a 7¢ increase starts February 18. A 6¢ jump goes into effect at Chance Vought (*Regulus*) on March 12 and a 7¢ hike begins at Convair Pomona and San Diego (*Atlas, Terrier* and *Tartar*) on April 1.

Douglas will pay 7¢ effective March 18 at plants represented by United Auto Workers and on April 1 at those involving International Assn. of Machinists. Rohr Aircraft also pays 7¢ starting April 15 and Boeing a similar amount on May 22 at its Seattle plants. Ryan Aeronautical will pay a 7¢ increase on July 8.

Computers—and the Engineer Shortage

Electronic computers, properly used, could produce a "new look" engineer and may be the answer to the current shortage of scientists and engineers, a computer symposium jointly sponsored by New York University and International Business Machines was told recently.

Daniel O. Dommasch, president of Dodco, Inc., predicted that the mechanical brains could achieve this end via their creative power of more than 30 present-day engineers.

The Dodco executive said computers would free engineers and scientists from making the physical and mathematical approximations that are necessary and would replace today's educated guesses with accurate numerical solutions. This abandonment of approximation would bring industry into the age of true science, he added.

Are You Looking For A Job... Or A Career?

For A Real Career Position... Read About These 12 Outstanding Openings At

WESTINGHOUSE-BALTIMORE

The 12 positions listed below are not just job opportunities — they are permanent career positions with an established leader in the electronics field. Westinghouse-Baltimore is an engineer's company — one that respects the engineer and rewards him for his contributions. The company's two new plants offer the very finest modern facilities and equipment for advanced work on vital projects that challenge the imagination and assure steady professional growth. These 12 opportunities may be the chance for which you've been waiting. Investigate them—and get in on the ground floor of tomorrow's electronic developments — at the rapidly expanding Baltimore Divisions of Westinghouse.

CURRENT OPENINGS EXIST FOR:

AIRBORNE RADAR SYSTEMS ENGINEERS

Overseas assignments on a research and development type project. An E.E. degree from an accredited college or university with additional training or experience on airborne radar systems is desirable. Applicants should be single, or willing to spend periods of six months to one year away from their families.

TROPOSPHERIC SCATTER SURVEY ENGINEERS

To work with the Air Force. Those selected would travel considerably here and overseas. The company would provide living allowances and salary bonuses for overseas service. Applicants should have an E.E. degree from an accredited university and two to four years experience with microwave communications systems. Additional experience in surveying and laying out microwave systems would be helpful.

ELECTRIC WAVE FILTERS ENGINEERS

To assist in the design and development of audio, i-f and r-f filters, to meet the increasingly difficult requirements of modern SSB receivers and transmitters, both high and low power, at frequencies up to and including UHF.

MISSILE RADAR SYSTEMS ENGINEERS

To do analysis of over-all systems requirements. Must be able to translate to block diagram requirements.

MATHEMATICIANS

Some radar systems experience is desired, or experience in the following related fields: Noise analysis, Anti-jamming or Electrical Counter Measures, Communications systems.

MICROWAVE DEVELOPMENT ENGINEERS

To do development for the functional block diagram state to a complete bread board model. Theoretical and practical knowledge in the field is desired.

MECHANICAL DESIGN ENGINEERS

For the mechanical design of X-ray equipment, and for the designing of equipment to permit use of isotopes for medical treatment while protecting hospital personnel. An M.E. degree is required.

SALES ENGINEERS

To work with regional sales force on preparation of diagrams of the customers' organization, knowledge of the functions of the various elements, definition of procurement cycles, indication of important people and recommendations on over-all relations; detailed planning and coordination of sales strategy and proposal preparation; direction of contact efforts; liaison with Product Planner; and dissemination of product information.

DIGITAL COMPUTER ENGINEERS

For the extensive application of present and future digital techniques to military problems. Applicants with background and interest in digital coding, digital programming, and in the necessary hardware to implement such systems would find immediate application in our present digital work and would be expected to originate future digital programs.

ELECTRONIC TRANSFORMER ENGINEERS

To assist in the design and development of audio, i-f and r-f coils, flea-power to 600 x 10^6 v-a, frequencies up to 1000 MC, both linear and saturable, involving problems of balance, shielding, bandwidth, insulation, heat transfer, wave shape, efficiency and regulation.

COMPONENTS ENGINEERS

For testing, evaluation and developing reliability programs for Electrical Components such as: switches, diodes, triodes, tubes, meters, resistors, capacitors, chokes, etc. Applicants must be qualified for standardization of components and interpretation of military specs.

MISSILES RADAR TEST ENGINEERS

To design intricate test equipment and assist in the testing and evaluation of developmental missiles target seeker systems.

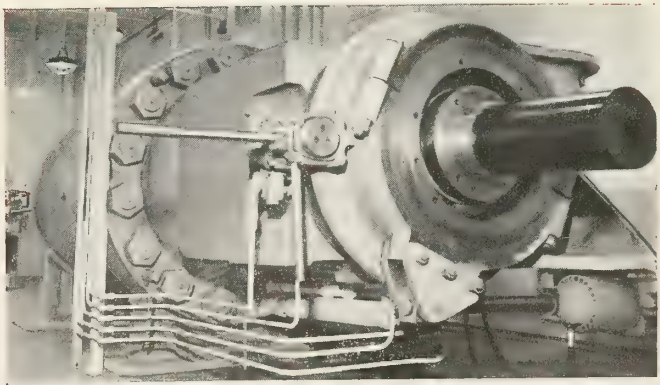
Phillips Cuts the Cost of

OCKET PROPULSION



with low cost PETROCHEMICAL INGREDIENTS

Phillips Petroleum Company has made an important contribution to the economics of rocketry by developing a series of powerful, *low cost propellants* from readily available materials. The Phillips operated Air Force Plant 66, near McGregor, Texas, provides complete facilities for designing, developing, and testing solid rockets and propellants. You are invited to discuss your problems in propulsion systems, primary rockets, booster rockets, and related matters with our staff of skilled scientists and engineers.

PHILLIPS PETROLEUM COMPANY
Bartlesville, Oklahoma

Address all inquiries to:
Rocket Fuels Division, Bartlesville, Okla.

Phillips 66

Giant extruders form solid propellants that are easily handled and can be stored for long periods.

tuned to the tempo of tomorrow

Open ears lead to the open thinking that made possible today's rocket powerplants. They are alert ears—ears acutely sensitive to the unsolved problems that must be conquered in designing powerplants for the vehicles of the future.

RMI puts a premium on just such thinking. Its engineers and scientists form a talented, alert team, efficiently and effectively meeting the rocket power needs of tomorrow.

Engineers, Scientists—Perhaps you, too, can work with America's *first* rocket family. You'll find the problems challenging, the rewards great.

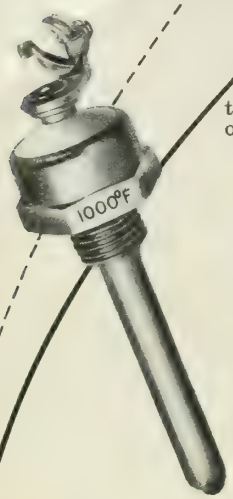
ARTWORK BASED ON OFFICIAL U. S. NAVY PHOTOGRAPH

GLOBAL GUARDIAN

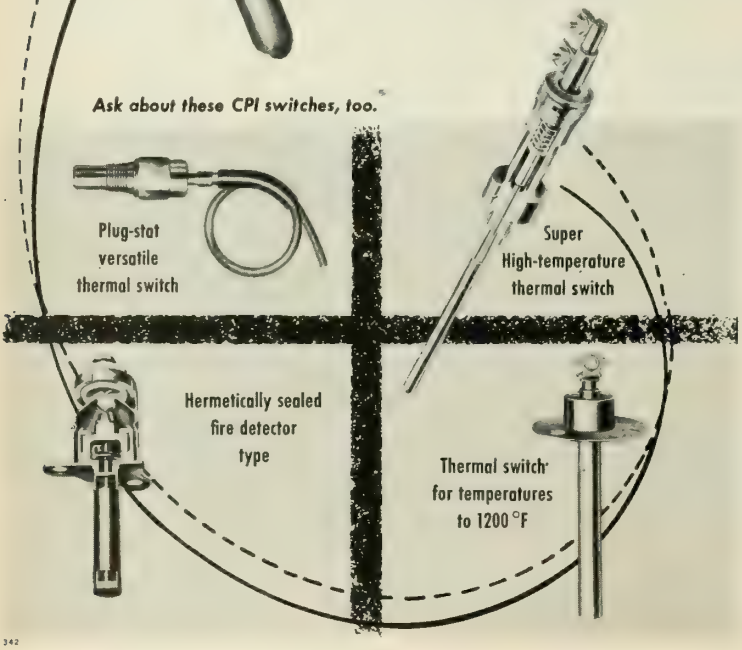


The Air Force's NAVAHO intercontinental strategic missile is near reality. How near is veiled in security. But we can tell you that it checks out as one of America's mightiest weapons in the struggle for peace. A major missile project executed in partnership with the U. S. Air Force, North American Aviation's NAVAHO development has accomplished the technical advances necessary to the production of an aerodynamic, supersonic, long-range guided missile. Bull's-eye accurate, and well nigh invulnerable to interception, the NAVAHO will extend this country's defense around the globe... at several times the speed of sound.

Engineers: write for details regarding challenging positions now open.

NORTH AMERICAN AVIATION, INC.

Los Angeles, Downey, Canoga Park, Fresno, California; Columbus, Ohio; Neosho, Missouri.



New CPI thermal switch is *Light and Lively*

This new lightweight (weighs less than one ounce) thermal switch features an operating differential of plus or minus only one degree with extremely fast response.

With an effective calibration temperature rating from —20°F +1000°F, it will even operate accurately when subjected to momentary undershoots to —80°F and overshoots to as high as 2000°F.

Wherever fast-acting, sensitive, thermally responsive regulation is required for control of dangerously high or low temperatures, this "LIGHT and LIVELY" switch will do the job accurately, dependably.

342

Ask our representative to tell you how CPI can help you solve your temperature control problem—and remember—when temperatures are high (or low) you can depend on CPI. Write for complete engineering data. Ask for catalog CA.

Gnat Rate Gyro
Shown actual size

GOLDEN GNAT

Miniature Rate Gyros for Missiles and Aircraft

Here is a precision, minature rate gyro. It's tiny . . . measures only 1 inch in diameter and 2¼ inches in length. It's rugged . . . withstands 100G shock and 10G vibration to 2,000 cps. It has a record of proven performance.

Even under the most severe environmental conditions the Golden Gnat will perform as required. To make this possible many unique design details have been incorporated. One such detail is the Gnat's *gold plated* steel housing for improved corrosion resistance and positive hermetic sealing.

Wherever the need exists for high performance miniature rate gyros such as for autopilot stabilization in missiles and aircraft, antenna stabilization and fire control applications, the Golden Gnat is ideally suited. Write for Bulletin GN . . . Minneapolis-Honeywell, Boston Division, Dept 00, 1400 Soldiers Field Road, Boston 35, Mass.

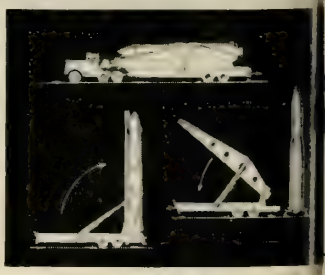
HERE'S HOW
SOLVE YOUR

WALLACE HAMILTON'S job is designing equipment for storing and transporting a missile and positioning it for flight. Mr. Hamilton is Chief Engineer of the Special Products Division and under his control over 100,000 annual man-hours of engineering talent are available for developing transtainers and launchers that use Cleveland Pneumatic's years of experience in designing and making heavy-duty equipment, shock absorbers and special mechanisms.



FOR ANY MISSILE, ANYWHERE.

Mobile heavy-devices lift built by Cleveland Pneumatic to raise a heavy weapon 150" from ground and position it within 1/32".

Servicing segment of missile work stand and tower as conceived by the project engineer of the Special Products Division.

Transporting vehicle with self-contai erector designed by the Spec Products Division, and capable of be built wholly in our shops.

OUR SPECIAL PRODUCTS DIVISION CAN MISSILE GROUND-SUPPORT PROBLEMS

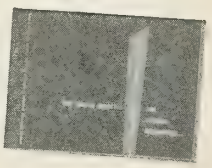
Now, every sub-project connected with the ground-support phase of your missile program can be combined into a single contract.

Save man-power. Save time. Concentrate your available engineering and manufacturing facilities on your missile project. Cleveland Pneumatic will handle the complete ground-support project for you and will provide single responsibility for the entire project from the time the site is cleared to finished launcher ready to fire.

LAUNCHING TOWERS AND TEST STANDS—Years of experience in the design and fabrication of heavy-duty structures and highly precise mechanisms and controls that can delicately adjust and position massive missile and structural components enable Cleveland Pneumatic to design all types of launching and test stands for any size missile including ICBM.

PORTABLE LAUNCHERS—Portable units make fullest use of our experience as a leading manufacturer of handling devices, hydraulic movers, mechanical actuators, and the required systems of interlocking controls and safety devices.

SHIPBOARD LAUNCHERS—Pitch and roll can be compensated by combinations of Cleveland Pneumatic hydraulic cylinders and National Water Lift Division zero-positioning actuators, working under the control of NWL hydraulic valves and controls.



GROUND TRANSPORT EQUIPMENT—Vehicles for transporting the missile to the launching site can incorporate impact-absorbing devices perfected by Cleveland Pneumatic.

ON-SITE SERVICES—Architectural and engineering services for on-site construction are available from Cleveland Pneumatic under our one-responsibility contract with missile builders.

The Special Products Division is ready to start today on your missile ground-support project. The result will be equipment that will provide maximum ease of handling and smooth operation, reducing the manpower and time required for your ground-support operations.

Your missile project... and creative engineering

This new booklet outlines in detail the abilities and facilities of the Special Products Division. For your copy write on your company letterhead to Cleveland Pneumatic Tool Company, Special Products Division, Cleveland 5, Ohio.

Rockets Have Peaceful Uses

Military developments have so far obscured all other present and potential uses of rockets that it almost seems anachronistic to discuss their peacetime uses.

This issue of Missiles & Rockets, however, states the "Rockets for Peace" case very clearly.

Much of the valuable data obtained by scientists in recent years about the upper atmosphere—data affecting our everyday lives in such fields as geodesy, meteorology, navigation, medicine, and others—would not have been available without high-altitude rocket research.

From the bits of information obtained from instruments in upper-air rockets, research groups throughout the country are gradually amassing a complete analysis of phenomena which have determining affects on such things as magnetic storms, radio black-outs and various other aspects of air navigation and weather forecasting.

Most of this work is being done under auspices of universities and is handicapped by insufficiency of funds. Even the work on upper-air research by the Office of Naval Research and by the Army and the Air Force is relatively insignificant in scope because of lack of funds.

True enough, an extensive program is scheduled for the International Geophysical Year, but it is still limited in view of what *could* be done.

A well-organized large-scale program is called for. Based on rockets now available and the number of scientists who have expressed interest in upper-air rocket research, the results could have a genuine impact on our civilization and incipient conquest of space.

The possibilities are so extensive that only the government, in the final analysis, can organize, sponsor and finance a large-scale program.

All that exists today in the way of centralized activity is an informal group that calls itself the Upper Air Rocket Research Panel. The members get together now and then to discuss informally their experiments and experiences. It could well be that this informal panel is the proper nucleus for an expanded national program.

WAYNE W. PARRISH

letters

What Is Lintz Basalt? Why Does It Defy Gravity?

To the editor:

The column "Missile Miscellany" of the February 1957 of MISSILES & ROCKETS contains a statement concerning the properties of a material referred to as "the silicate, Lintz basalt." According to this, Lintz basalt generates heat spontaneously at 2.36×10^4 calories per hour per gram, and in free fall won't accelerate at 980 centimeters per second^2. I am sure you will agree the latter in particular is an amazing quality.

I would like to obtain more information concerning Lintz basalt.

I enjoy reading MISSILES & ROCKETS and find it contains a great deal of interesting and valuable information.

Dr. Paul W. Kruse
Senior Research Physicist
Minneapolis-Honeywell Regulator Co.
Hopkins, Minn.

To the editor:

If you have further information on item 2, Missile Miscellany department, page 99, February 1957 issue, it will be greatly appreciated.

G. M. Greene
Asst. to Vice President-Engineering
Hughes Aircraft Company,
Culver City,
California

To the editor:

In reading MISSILES AND ROCKETS, Feb. 1957, a short paragraph in the Editor's Column, page 99, stated among other things, *"The silicate, Lintz basalt . . . in free fall condition does not accelerate at 980 cm/sec^2"*

. . . Any further information that you have on this matter would be appreciated.

Mr. Charles Summes.
2186 47th St.,
Los Alamos, N. Mex.

To the editor:

In the February issue of m/r in the "Missile Miscellany" column on page 99, you made the statement, "why in free fall (the silicate, Lintz basalt) won't accelerate at 980 cm/sec^2." . . . I would like to see your source.

Incidentally, I enjoy your magazine very much. This latest issue on Russian missiles is excellent.

Leslie M. Bagnall
5840 Coleman Street
Fort Worth, Texas

To the editor:

In answer to your questions in your "Missile Miscellany" column in the February issue of m/r: Has anyone ever used modern theory to explain why the silicate, Lintz basalt . . . may I suggest that there may be a correlation between these phenomena and those observed in the so-called Biefeld-Brown Effect . . . and that the answers to your questions might properly be found in the current research that is now going on with regard to "anti-gravity" . . .

I think it would be very interesting if you would report on current progress in "anti-gravity" research.

Clifford B. Haughton, Jr.
Senior Development Engineer
Gas Turbine Department
Lycoming Division
Avco Manufacturing Corporation
Williamsport, Pennsylvania

The work with Lintz Basalt was performed by Charles Francis Brush and was later checked out by the National Bureau of Standards. The reference for the item in "Missile Miscellany" is as follows: The Proceedings of the American Philosophical Society; Vol. 65, April 23, 1926, a paper by Brush—Ed.

Glad Missiles May End War

To the editor:

. . . I am a civilian instructor in electronics fundamentals at Lowry AFB in the guided missile school and I felt quite encouraged by your optimism that missiles and rockets may be the means of ending wars . . . The senior instructor in our branch subscribes to your magazine MISSILES & ROCKETS and we find that it enables us to gain a much broader view of the whole industry than we could otherwise . . .

George James Pritchette
850 Oliver St.,
Denver, Colo.

Builds Solid Fuel Ramjet

To the editor:

. . . We at Experiment Incorporated were very pleased to see the mention of solid fuel ramjets by Alfred Zaehringer in "Propulsion Notes" (December m/r), since this is a subject close to our hearts.

The initial investigation of this engine type in the United States was made by Experiment Incorporated and Continental Aviation and Engineering Corporation. Later, Experiment Incorporated conducted a research and development program for the Navy Bureau of Ordnance which included flight tests, in January 1952, at NOTS China Lake.

These tests represented the first successful supersonic flights of a solid fuel ramjet (contrary to m/r's information that ". . . SF ramjets have been 'flown' only in test stands . . ."). Incidentally, both the PTV—N—4e flight vehicle and the solid fuel ramjet engine which powered it were designed and fabricated by Experiment Incorporated. Attached is a photograph of the vehicle ready for launching.

Other pioneers in this field were NACA and the Bureau of Mines . . .

V. W. McMahill, Jr.
Contracts Manager
Experiment Incorporated
Richmond 2, Virginia

Would See Satellite Launch

To the editor:

I am a sophomore in North Platte Senior High School and am very much interested in Missiles and Rockets. I would like to be present at the launching of the Satellite in Florida. Would you please give me the address of whom to write for further information regarding whether I could secure permission to be present at the launching.

Thanking you very much in advance. I enjoy your magazine MISSILES & ROCKETS very much and have increased my knowledge greatly through your magazine

Robert D. Stensvad
811 E. Third St.,
North Platte, Neb.

The Department of Defense is horrified at the thought, but maybe if enough people write requesting permission to see Vanguard take off, something will be done to make it possible. Write to: Cmdr. V. C. Thomas, Navy Press Desk, Office of Public Information, Department of Defense, Washington 25, D.C.—Ed.

Why No TV in *Vanguard?*

To the editor:

What with all the talk of establishing tracking systems for the satellite program, I'm a little surprised to read that nothing has been mentioned about installing a TV or movie camera within one of the satellites to provide us earth-bound creatures with a view of our earths' area as the satellite goes whizzing by. Has this been thought of and found impractical, or what? TV cameras are available which are small and powerful; and movie cameras, also small and able to operate by remote control, could be jettisoned automatically and parachuted to earth before the satellite burns itself out. Just curious.

R. Paulson
332 Prospect
La Jolla, Calif.

It would take a satellite weighing 100 lbs. to carry a TV camera and power supply. The current launching system is designed for only 21 lbs. USAF is working on camera equipped satellite. —Ed.

Would Banish LOZ, LOX

To the editor:

. . . Your recent "Propulsion Notes" by Alfred J. Zaehringer (m/r, December 1956) contained a reference to liquid ozone that stirred the cobwebs of my memory and recalled a shattering experience that occurred back in the early days (some ten months ago) of ozone research.

I refer to Mr. Zaehringer's coinage of the word "LOZ" as a contraction of "Liquid Ozone." One of our research engineers, brought up in the LOX school of rocket technology, boldly prepared a report that not only pushed back the frontiers of science, but also tried to

expand the confines of lexicography by mating the initial letters of "liquid" and "ozone" and giving birth to "LOZ."

The blessed event was viewed with disdain by an Ivy league chemistry professor who reviewed the report and commented as follow:

"——Now, turning from the sublime to the ridiculous, we have the question of lox and loz. I understand the derivation of the word lox as you use it, but I do feel that the salmon should have a voice in this matter. This business of loz is louzy. In your recent communication there is difficulty in separating 1 oz. and loz. It would also seem much better English if this word would be loze, but that makes it even more ridiculous, because people will think we are a theater chain of the same name.

Yours for Fowler's Modern English Usage."

LOZ thereupon died a painless death. The rebirth was inevitable, but we write in hope (but hardly expectation) that we can kill off the little offender once and for all . . .

Stephan Kidd

Solar Is Big Missile Supplier

To the editor:

. . . Congratulations on MISSILES & ROCKETS. I have just had the pleasure of seeing your December issue and wish to congratulate you on the material it contains as well as the interesting way in which it is presented. The chart "Subcontractors', Guide to Missile Production and typical Contractors," appearing on page 130, was of particular interest. We were somewhat surprised to note that the Solar Aircraft Company's name was omitted from this chart.

Solar's interest and activity in the missile field extends back for some years. We participated in the original development and manufacture of the *Hermes* missile and the *Corporal* rocket engine. Our activities in the missile field have continued to grow. Not only do we manufacture missile components for Aerojet-General Corporation, Jet Propulsion Laboratory and Rocketdyne, a division of North American Aviation, Inc., but we also manufacture the fuselage for the Falcon missile on a subcontract for Hughes Aircraft Company.

Fred S. Hage, Jr.
Director of Public Relations
Solar Aircraft Company
San Diego, Calif.

Would Reproduce m/r Article

To the editor:

. . . I thought it an excellent job and you may be sure that it has received favorable comment from many of our people.

May we trouble you once more for written permission to reproduce? I'd like to distribute copies of the General Medaris article and the one on the Aeroballistics Lab to interested personnel . . .

Gordon L. Harris
Public Information Officer
Army Ballistic Missile Agency,
Huntsville, Alabama.

High School Rocket Engineers

To the editor:

After reading the article on "Education . . . for the Missile Age" by Kurt R. Stehling, I felt that another phase of missile education which has been in most cases sadly neglected, should be mentioned. This is the phase including amateur study and experimentation which is presently being carried on at the high school level by many individuals.

Among these is the Seattle Astronautical Research Society, a group of high school students interested and presently majoring in science with a slant toward rocketry. This group, of which I am a member, has been studying astronautics for over 2½ years, and has carried on experimentation for the past 1½ years in static testing of rocket motors.

With the help of the Northwest Section of the American Rocket Society, and companies in various parts of the nation, we have been able to gain a wealth of knowledge and practical information on the science of rocket motors.

However, the attitude of complete indifference shown by some large corporations to our endeavors has made us question the extent of demand for scientists and engineers in the field of missiles and rockets.

I believe a well-supervised, nationwide program for potential missile engineers should be organized to catch interest where it counts most: At the point in high school at which students decide on vocations and colleges.

Leon Leonard, Research Director
The Seattle Astronautical Research Society
17347 Densmore Ave.,
Seattle, Wash.

Keep up the good work, Leon—Ed.

Solid Rockets Not So Safe

To the editor:

With reference to your article, "Break-up in Army-Navy Jupiter Program," I fear you are guilty of some unnecessary over-simplification in describing the advantages of solid propellants. In particular, I refer to the following:

> "The solid rocket doesn't require the outer shell or container. It doesn't require the propellant insulation gear nor any additional booster or torpedo powerplant. Pressurization requirement is insignificant.
>
> "Furthermore, because of the water resistance, a missile moves rather slowly underwater. It burns only a small amount of propellants before popping out of the sea; the water back pressure on the combustion holds the burning back."

Published data on solid propellants, both composite and double base types, indicate an increase in burning rate, rather than a decrease, with an increase in pressure. Of course the "mesa" type discontinuity exhibited by double-base propellants tends to minimize this dependence of burning rate on pressure. The effect of initial propellant temperature on its performance has been one of the primary disadvantages of its use. Some . . . of the propellants in use are extremely hygroscopic and require extreme care in handling and packaging . . .

Matthew J. Pastell
2210 W. 169th Pl.,
Torrance, Calif.

Missile Reliability Road Show

To the editor:

I read with great interest your Industry Highlights Section of MISSILES & ROCKETS issued in December, 1956, in particular about the Reliability Road Show that the Hughes Aircraft Company has provided for their subcontractors.

We of the Bendix Missile Section are completing a second Reliability Road Show . . . featuring a new movie producted by Bendix entitled *"Talos*—Flight 440." This movie deals with workmanship problems and their effect on the overall reliability of the *Talos* Missile... this show explained in the layman's language the meaning of reliability to the *Talos* workers . . .

Questionnaires were submitted to workers . . . soliciting comments. These comments . . . pointed out that normal aircraft standards that have been widely accepted by the industry are not adequate for the missile industry.

The information supplied by these questionnaires indicated that many intangible benefits have been brought about and we are certain that over-all missile reliability will benefit from the fact that each worker in the *Talos* program now has a better understanding of the importance of top workmanship and the necessity for personal responsibility on his part.

R. R. Wendt
Project Engineer
Reliability Department
Bendix Aviation Corp.,
South Bend, Ind.

Who's On Top?

To the editor:

One of our subscribers to THE ENCYCLOPEDIA AMERICANA has requested information which you may be able to supply.

The subscriber would like to know "What is the record height attained, in miles, by a man-made rocket or missile. I'm interested in distance straight up, rather than horizontal distance traveled."

We would appreciate any help you can give us with this matter. Thank you.

Margaret M. LaSala,
The Americana Institute.
2 W. 45th St.
New York 36, N.Y.

The official record is held by a two stage vehicle consisting of a V-2 and a WAC-Corporal fired from White Sands, New Mexico, in December of 1949. It went 250 miles up. However, the actual record—unofficial because it hasn't been publicly announced by the Pentagon—is held by a Jupiter-C missile fired by the Army Ballistic Missile Agency from Patrick Air Force Base on September 20, 1956—680 miles which would seem to be more out than up.—Ed.

Where do you belong in

Computer Circuit Design Engineers plan electronic circuitry for advanced airborne analog and digital computers . . . design linear and pulse circuits employing transistors, tubes, magnetic devices. Opportunities also exist in airborne power supply design, or to develop new techniques for marginally checking computer performance. *Do you belong on this team?*

Computer Logical Design Engineers determine the systems outline of a computer and its inter-connection with external equipment. Close liaison is maintained with mathematical support, circuit design, packaging and test engineers. Computer speed, memory size, configuration and arithmetic structure are tailored to requirements of weapons systems. *Do you belong on this team?*

Systems Evaluation Engineers test and evaluate electronic analog and transistorized digital computer systems design for aircraft; evaluate new systems and improvements to insure compliance with specifications and Air Force requirements. Other assignments: tie-in testing of peripheral equipment, liaison with design, development and field engineering. *Do you belong on this team?*

Harry Branning (center): B.S.E.E. 1950, Syracuse. Design Engineer in circuit design, 1951; October, 1954, promoted to Associate Engineer; April, 1956, promoted to Staff Engineer, Systems Planning. In June, 1956, appointed Project Engineer and Manager of the 110 Computer Circuit Design Department; discussing the performance and packaging details of a transistorized read amplifier.

William Dunn (standing): M.E. 1950, M.S.E.E. 1952, Stevens Institute. Technical Engineer, 1955; April, 1956, promoted to Associate Engineer; August, 1956, transferred to Development Engineering in charge of Logical Design for digital computers in advanced weapons systems; here discussing Boolean Algebra method of optimizing the logical design of an airborne digital computer.

Eli Wood (left): B.S.E.E. 1950, Connecticut. IBM Customer Engineer, July, 1950; September, 1952, transferred to ACL Field Engineering. February, 1954, in charge of Field Engineering at Hunter AFB; May, 1955, Associate Engineer; appointed Project Engineer, Manager of Systems Evaluation in August, 1956; here investigating a problem in radar data presentation set evaluation testing.

The brief records of the men cited above indicate only a few of the exciting activities right now in IBM Military Products. This division, organized 18 months ago, has grown enormously. A small-company atmosphere prevails. Men work in small teams . . . individual contributions are instantly recognized. Promotions occur frequently.

As a member of IBM Military Products, you'll enjoy physical surroundings and equipment second to none. Educational programs at IBM expense lead to advanced degrees. Salaries and benefits are excellent. Stability is guaranteed by IBM's history of consistent achievement—underlined by the fact that the rate of turnover at IBM is only one-sixth the national average.

Throughout the length and breadth of the United States IBM has built modern plants and laboratories. This map points out the various locations where you might live as an IBM em-

IBM Military Products?

Systems Engineers oversee the engineering support provided by the Systems Coordination and Specification Group to the factory on the AN/ASB-4 Bombing-Navigational System. Air Force requirements are analyzed and the resulting engineering changes evaluated to determine effect on system performance and accuracy. Mathematical error analyses are run. *Do you belong on this team?*

Systems Analysts anticipate performance and recommend design criteria before and during development of equipment. Later, they compare dynamic performance accuracy and reliability characteristics with what has been anticipated. Other assignments include Digital Computer Systems Engineering, Input-Output and Analog-Digital Conversion Engineering. *Do you belong on this team?*

Quentin Marble (left): B.S.M.E. 1951, Syracuse. Joined IBM in 1951; promoted to Design Engineer in 1952; May, 1955, promoted to Associate Engineer, and then to Project Engineer, Manager of the Systems Coordination and Specification Group, Production Engineering Department, in February, 1956; shown here describing a unique cooling design to a new employee in his group.

Monroe Dickinson (left): B.S.E.E. 1952, W.P.I.; M.S.E.E. 1954, M.I.T. Technical Engineer in analog and alternate computer techniques for weapons systems, 1952; Associate Engineer responsible for systems design and analysis, 1954; December, 1955, Staff Engineer, responsible for research planning; here reviewing set-up on laboratory analog computer of a sampled data control problem.

Exceptional career opportunities are now open in IBM Military Products for E.E.'s, M.E.'s, physicists, and mathematicians, in the following fields:

SYSTEMS PLANNING AND ANALYSIS
DIGITAL AND ANALOG SYSTEMS
INERTIAL GUIDANCE
SERVO-MECHANISMS
ELECTRONICS
MECHANICAL DESIGN
ELECTRONIC PACKAGING
PROGRAMMING
FIELD ENGINEERING
RELIABILITY
COMPONENTS
PHYSICS
MATHEMATICS
HUMAN ENGINEERING

ployee. IBM Military Products include the Airborne Computer Laboratories located in Owego, N. Y., and the Project SAGE installations directed from Kingston, New York.

Here is a real ground-floor opportunity that you can't afford to overlook. Without exaggeration, your potential in this dynamic young field of electronic computers is virtually unlimited. Get all the facts. Write, outlining your background and interests to:

R. A. Whitehorne
Manager of Engineering Recruitment, Dept. 6903
International Business Machines Corp.
590 Madison Ave., New York 22, N. Y.

Can you use the talent that built 1,500 Y-4 bombsights on schedule?

These General Mills technicians are representative of the production talent that built more than 1,500 Y-4 bombsights, 1,500 coordinate converters, 1,400 azimuth and sighting angle indicators and 1,400 amplifier and power supply units—and, delivered them to the Air Force *on time*. Here the men inspect a bombsight before it progresses to the next stage of production.

Because we have the highly skilled men—and the men have the specialized tools and machines—we produce precision piece parts or complete, complex assemblies to meet the most exacting requirements.

While building the Y-4 bombsight, we improved original design, exceeded USAF specifications. In addition, our thorough testing facilities assured delivery of only perfect instruments.

Such performance has come to be expected of us and has benefited many other customers. We'd like to help with your production problems too.

Booklet Tells More, explains mechanical and electro-mechanical production facilities. Send to Dept. MR-3, Mechanical Division, General Mills, 1620 Central Ave. N.E., Minneapolis, Minn.

No slow-downs for the B-47— Bombsights ready in advance! During production of the B-47 Stratojet, not a one was kept from the ready-line for lack of a bombsight. The same developmental, engineering and production skills that gave the Air Force on-time delivery are available to speed production of your products

IS YOUR JET ENGINE RPM MEASUREMENT ACCURATE AND SAFE?

TAKCAL®

READS JET ENGINE SPEED to GUARANTEED ACCURACY of 10 RPM in 10,000 RPM (±0.1%)

The inter-relation of RPM to efficiency and thrust in jet engines is fundamental. Proper adjustments for maximum thrust, maximum engine life and maximum safety of operation can be made only upon accuracy of instrumentation. The TAKCAL tests to guarantee that accuracy.

The new B & H TAKCAL incorporates a refinement of the frequency meter principle. It operates in the low (0 to 1000 cps) range, reading the frequency of the tachometer generator on a scale calibrated in percent RPM corresponding to the engine's RPM. It reads engine speed while the engine is running with a guaranteed accuracy of ±0.1% in the range of 0 to 110% RPM. Additionally, the TAKCAL circuit can be used to trouble-shoot and isolate errors in the aircraft tachometer system, with the circuit and tachometer paralleled to obtain simultaneous reading.

The TAKCAL's component parts are identical with those used in the J-Model JETCAL Analyzer. They are here assembled as a separate unit tester and for use with all earlier models of the JETCAL Tester.

The TAKCAL operates accurately in all ambient temperatures from −40°F. to 140°F. Low in cost for an instrument of such extreme accuracy, it is adaptable to application in many other fields.

For full information write or wire . . .

CHECKS TACHOMETER "SYSTEM" ACCURACY.
ADAPTS TO ANY FREQUENCY PROBLEM!

Explosion-proof TAKCAL for special applications. Measures 200 to 7500 RPM, direct reading, with ±0.1% accuracy.

MISSILES ENGINEERS...

Let's exchange resumes

NAME:
Douglas Aircraft Company, Inc.

POSITION:
World's largest manufacturer of aircraft and missile systems.

LOCATIONS:
Santa Monica, California
Naval Air Missiles Test Center
Point Mugu, California
Edwards Air Force Base, California
White Sands Proving Grounds
Las Cruces, New Mexico
Air Force Missiles Testing Center
Patrick Air Force Base
Cocoa, Florida
Holloman Air Development Center
Alamogordo, New Mexico

AGE:
15 years in missiles; 37 in aircraft.

EDUCATION:
An engineering company managed by engineers — such as Donald W. Douglas, B.S., Aeronautical Engineering (M.I.T.); F.W. Conant, B.S., Civil Engineering (Cornell); and A. E. Raymond, B.S., Mechanical Engineering (Harvard), M.S., Aeronautical Engineering (M.I.T.), and Ph.D. (Hon.) (Polytechnic Institute of Brooklyn) — and with key staff positions held by graduate engineers, physicists and mathematicians, many with advanced degrees.

EXPERIENCE:
Pioneers in missile research development and production since 1941.

Major contractors for air-to-surface, surface-to-surface, air-to-air and surface-to-air missile systems.

Designers of auxiliary equipment to transport and launch guided missiles.

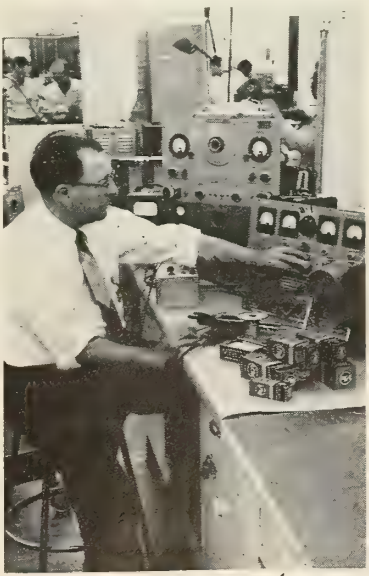
Establishment of a completely separate missiles division in 1956.

Now responsibile for nine separate missile projects — including such "veterans" as Nike I (1945 to present) and Sparrow (1947 to present).

Extensive flight test experience at proving grounds across the country where Douglas engineers are assigned.

Missiles experience supplemented by 37 years in airframe design, development and manufacture.

REFERENCES:
The U.S. Army, Navy and Air Force.



Thousands of manufacturers of components for missile systems.

Some 1600 Douglas employees now engaged in missile work.

SPARROW I, the Navy's supersonic air-to-air guided missile, intercepts targets even under evasive action.

SERVO AMPLIFIERS used with a four-way electrohydraulic valve being tested by Douglas electronic engineer.

New magnesium alloy holds properties for 100 hours up to 700°F.

Dow Magnesium HM21XA-T8 alloy extends further the range of conditions under which light metals can be used in aircraft design. Second in the series of sheet alloys designed specifically for elevated temperature applications, it supplements the excellent characteristics of HK31A alloy.

HM21XA-T8 retains its properties at temperature during long periods of time. Even one hundred hours at 700°F. results in relatively little change in tensile yield, creep and elastic modulus.

Magnesium lightness is combined with strength at elevated temperature in HM21XA-T8, offering new ways to save weight or gain increased rigidity in the design of missiles and aircraft. This alloy is supplied in the -T8 temper and can be formed in this temper without the need for further heat treatment after fabricating. Samples of HM21XA-T8 along with detailed information are available. Contact your nearest Dow Sales Office or write to THE DOW CHEMICAL COMPANY, Midland, Michigan, Department MA 1400G.

YOU CAN DEPEND ON DOW

spoon at work...

A principle is at work, too! The same one by which a spoon creates a "silent cycle" of conduction, radiation and convection that cools the coffee—now, effectively applied, increases electronic equipment reliability.

Electronic reliability engineers are learning how to beat *heat* (the most frequent cause of electron tube failures and resultant equipment unreliability) with the "silent cycle" effectiveness of IERC Heat-dissipating tube shields. IERC's extensive research has resulted in the *only* Heat-dissipating tube shield that gives you maximum effectiveness in *all* three phases of the "silent cycle"—conduction, radiation and convection! Service in severe environmental conditions in many military and industrial equipments proves IERC shields reduce tube operating temperatures as much as 150° C—extend tube life up to *12 times longer! Excellent retention and shock and vibration protection is also provided.

IERC tube shields are available for miniature, sub-miniature, octal and power electron tubes.

book reviews

The Zeppelin in the Atomic Age. *By Edwin J. Kirschner, 100 pp. $3.50, The University of Illinois Press, Urbana, Ill.*

The rigid airship (or zeppelin) may be with us again, this time with nuclear-powered engines. Certain obvious uses for the atomic-powered rigid airship are pointed out—as a missile launching platform and anti-missile defense weapon.

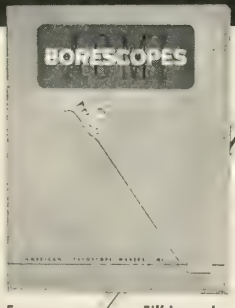
The author makes a strong case for the redevelopment and use of the rigid lighter-than-air aircraft. He cites facts and figures showing that there is a place in the commercial transportation picture for aircraft that is faster than the steamship and can carry more than the airplane. Since national policy greatly influences the total transportation system, he proposes an overall national transportation agency that would also encourage the development and operation of the extra long-range zeppelin.

The military rigid airship would be versatile and capable of performing many jobs where speed is not the sole criterion. Other important factors are also taken into account: cost, capability, utilization, safety, and dependability. Radar-equipped rigid airships could provide a relatively permanent electronic-detection umbrella as early-warning outposts to the Western Hemisphere and around the world. Present airborne and ground-radar equipment have their operational limitations, while an early-warning rigid airship, powered by nuclear engines, would be capable of carrying powerful radar equipment, and of extending the range of our early warning system a reported 500 miles.

To make the early-warning airship "combat ready," it could be designed to house, send off, and hook on to parasite jet fighters, and operate platforms for firing rockets and missiles in defensive and offensive military operations. Such a weapon Kirschner predicts would be capable of radar surveillance and to interdict an attack before it could reach the Western Hemisphere, at the same time dealing an immediate counteroffensive. The existence of such a force as this encircling the American continent would aid in making an attack unprofitable to the enemy anywhere within the range of these aerial 'minute men' platforms.

The author particularly sees the atomic-powered airship as an aerial reconnaissance ideally suited for the kind of patrolling suggested by President Eisenhower's "open-sky" plan. It would be used as a platform in conjunction with jet-photo aircraft or satellite platforms for special inspection assignments requiring close examination of critical areas for indefinite periods of time.

The first part of the book is devoted to an illustrated history of lighter-than-air aircraft. Our airship history has shown that the United States has lacked experience and interest in the development of the rigid airship. Until now, the United States has built only three rigid airships and flown four. The fourth was the *Los Angeles* which was built in Germany and successfully operated by the U.S. until its retirement before the Second World War. Germany has built more successful rigids than all the rest of the world combined—approximately 150—and is commonly accepted as the foremost airship nation in history.



The spectacular death of the German hydrogen-filled *Hindenburg* at Lakehurst, New Jersey, in 1937 sparked a staggering blow to zeppelins in the U.S. Thirteen persons were killed. At the time, the U.S. National Advisory Committee for Aeronautics reported that airships had helped aviation development tremendously and could contribute much more of value to the future of aeronautics. They emphasized that the airship should not be allowed to stand idle while other branches of aeronautics are developed.

An economical and safe aircraft is pictured by Kirschner for the atomic-powered, helium filled, rigid airship. The book is highly interesting, and merits consideration for vocational purposes.

A Technical Dictionary of Rockets and Astronautics. *By Glauco Partel (A.I.R.), 107 pp. $1.61, Published by Istituto Poligrafico Dello Stato G. C., Rome, Italy.*

This paper-bound dictionary lists over 1300 rockets and astronautics terms in Italian, German, English and French in four side-by-side columns. Included also are word finder lists in all four languages as well as extension conversion tables from the metric to the English system and back. It is a complete presentation in all four languages and should be a very valuable addition not only to technical libraries but to the collection of handbooks and the like scientists and engineers keep on their desks.

INSPECTION PROBLEMS?
This booklet is for you!

This comprehensive, elaborately illustrated booklet provides practical information on the use of the famous A. C. M. I. Borescope in various industries, for the inspection of interior areas or surfaces not otherwise visible—together with full data on the types of Borescope available, and on their care and maintenance. Have you received your copy?

Free on request *Fill in and mail today*

To *American Cystoscope Makers, Inc.*
1241 LAFAYETTE AVENUE NEW YORK 59, N. Y.

Gentlemen: Please send me without obligation a copy of your booklet on Borescopes.

MOLYKOTE® LUBRICANTS . . .
ALREADY SOLVING PROBLEMS IN THE AGE OF ASTRONAUTICS

Born in the "fringe area" of industrial lubrication, MOLYKOTE Lubricants have grown under the pressure of the toughest problems industry has to offer. Extreme pressures and temperatures: unusual environments, high starting friction, resistance to centrifugal force, obstinate fretting . . . MOLYKOTE has solved many. Truly, MOLYKOTE has been called "Industry's Most Versatile Lubricant".

To the Age of Astronautics MOLYKOTE brings ● THERMAL STABILITY, retaining its lubricity from -300°F to 700°F in air. 2000°F in vacuum ● CHEMICAL STABILITY, resists all but a few strong acids ● A NATURAL AFFINITY for adherence to metal, rubber, plastics, etc. ● A FAVORABLE LUBRICANT structure. Low friction sliding surfaces are an integral part of the molecule ● RESISTS PRESSURES beyond the yield point of any metal.

Send today for complete data on the entire line of MOLYKOTE Lubricants.

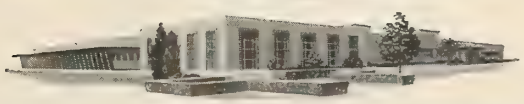
U. S. TIME GYROS IN CONTROL



The development and production of sub-miniature precision gyroscopic type instruments are exacting problems. These problems can only be solved by combining the skills of creative, seasoned research development and production engineers within the framework of an organization long experienced in the problems of precision instrumentation.

Important example of U. S. Time's present role in the gyroscopic field has been the volume production of sub-miniature precision rate gyros. More than seven thousand of these precision-built rate gyros are currently being used in guided missiles, antenna stabilization systems, autopilots, damper systems and stable platforms. The performance characteristics of these rate gyros can be modified to suit your specific requirements.

U. S. Time's new enlarged research staff and facilities are engaged in research, design and development of miniature precision instruments—instruments to withstand and perform under the severe environment of supersonic aircraft and missile flight.

We invite inquiries in the following fields of precision instrumentation:

STABLE PLATFORMS • FLOATED INTEGRATING GYROS • ACCELEROMETERS • RATE GYROS • TWO AXIS GYROS • DAMPER SYSTEMS • INERTIAL INSTRUMENTATION • GUIDANCE SUB-SYSTEMS

PHILLIPS OFFERS

SCIENTISTS AND ENGINEERS EXCEPTIONAL OPPORTUNITIES IN ROCKET DEVELOPMENT

Challenging positions are now open at Phillips Petroleum Company for scientists and engineers interested in the rapidly expanding field of rocket propulsion. The Phillips operated Air Force Plant 66 near McGregor, Texas, provides complete facilities for designing, testing, and manufacturing propellants and rockets. Phillips Petroleum Company has developed a whole new series of low cost, petroleum-derived propellants which are helping to revolutionize the rocket industry. *There's a future with Phillips.* Confidential interviews will be arranged for qualified applicants. Write for complete information

Giant PUSHER rocket made from low cost, petroleum-derived materials gives tremendous thrust for short durations.

USAF to Start Moon Rocket Program

Vehicle Circling The Moon Will Be Ready In Less Than Five Years; Companies Rush Proposals; Convair Heads List Of Hardware Bidders

By Erik Bergaust

SAN DIEGO—What might turn out to become the most significant event of our century has been confirmed to m/r during the Convair/AFOSR space flight symposium here: the Air Force is getting ready to start a moon rocket program.

In an exclusive interview Brig. Gen. Hollingsworth F. Gregory, Head of the Air Force Office of Scientific Research, told this reporter the Air Force "probably will have a rocket circling around the moon in less than five years."

"Several moon rocket study contracts are in the works," the general said, "and it is imperative that we carry out these scientific research projects to stay ahead of the Russians. When I say that we will have a moon rocket in less than five years, it is a conservative estimate."

The general also confirmed that ICBM power-plants are likely to be used for the Air Force moon rocket, and that it might be considered a "logical step" to launch "modified" ICBMs toward the moon as part of the Air Force training program for ICBM launching crews.

During the three-day symposium m/r also learned reliably that Convair is heading the list of companies about to submit proposals for actual hardware contracts for Air Force moon rockets. Other companies include Lockheed, Marquardt, Boeing, Douglas, Martin, Grand Central Rocket and Systems Laboratories. Most of these companies are involved in moon rocket study work. Convair's proposal is said to involve a circumlunar vehicle with a 200-pound payload consisting of camera and "television" equipment.

The Rand Corporation, meanwhile, has been conducting a moon rocket *study* for the Air Force for some time, and other study contracts for the various phases involved in launching lunar vehicles have been let but not disclosed, although it is known that Systems Laboratories has an AFOSR contract.

In a banquet speech here Western Development Division Commander General Bernard A. Schriever indirectly confirmed the possible availability of ICBM engines, components and hardware for the forthcoming lunar rockets. He said that out of the tremendous IRBM/ICBM effort will come a wealth of design information and hardware that will be useful for other things beyond that for which they were designed. These airframe, propulsion, and guidance subsystems developments and the data which will become available as ballistic missile test flights are made, will make possible a whole series of follow-on projects.

"The same propulsive unit that boosts a heavy nose cone-warhead to 25,000 feet per second, could boost a somewhat lighter body to the escape velocity of 35,000 feet per second or to an orbital path around the earth, General Schriever said.

"Using the same number of stages, the ratio of thrust to weight would be greater by using a lighter payload, and higher accelerations and velocities could be reached before burnout. Or with our present state of knowledge, it would be relatively easy to add another stage. We have already done that successfully on our re-entry test vehicle, the X-17. The same guidance system that enables the warhead of a ballistic missile to reach its target within a permissible accuracy would also be sufficiently accurate to hit a target much smaller than the size of the moon, even at that increased range," General Schriever said.

Brigadier General Hollingsworth F. Gregory tells m/r how Air Force hopes to send rocket to the moon.

Two Inevitable Moon Rockets

According to some of the nation's top missile and rocket engineers here two different moon rocket projects will be attempted within the next few years. A relatively small rocket—such as has been studied by the Rand Corporation (see line drawings)—will be built to land on the moon's surface. A second type, the circumlunar vehicle, will be brought into an orbit that takes it around the moon and back to earth, although it will not be attempted to retrieve the rocket. "I think this is the kind of lunar rocket that we will attempt first," General Gregory told m/r. This vehicle might carry up to 200 pounds of electronic video tape recorder equipment. Pictures will be taken of the moon's unseen side while it is illuminated by the sun, and as the rocket "returns" to earth the stored information will be transmitted back to earth.

Tribute to Air Force Office of Scientific Research

General Hollingsworth F. Gregory, outspoken scientific-minded Air Force brigadier general, told m/r AFOSR's mission is one of fundamen-

tal, theoretical or experimental investigation to increase man's knowledge and understanding of the natural world and to "recognize the implications of new scientific knowledge upon weapon systems concepts." Its capability to carry out this mission is represented by scientists throughout the free world working in universities, in industry, in foundations, and in government agencies under approximately 650 research contracts totaling about $30 million awarded by his organization, he said.

Exploratory Research Provides Capabilities For New Concepts

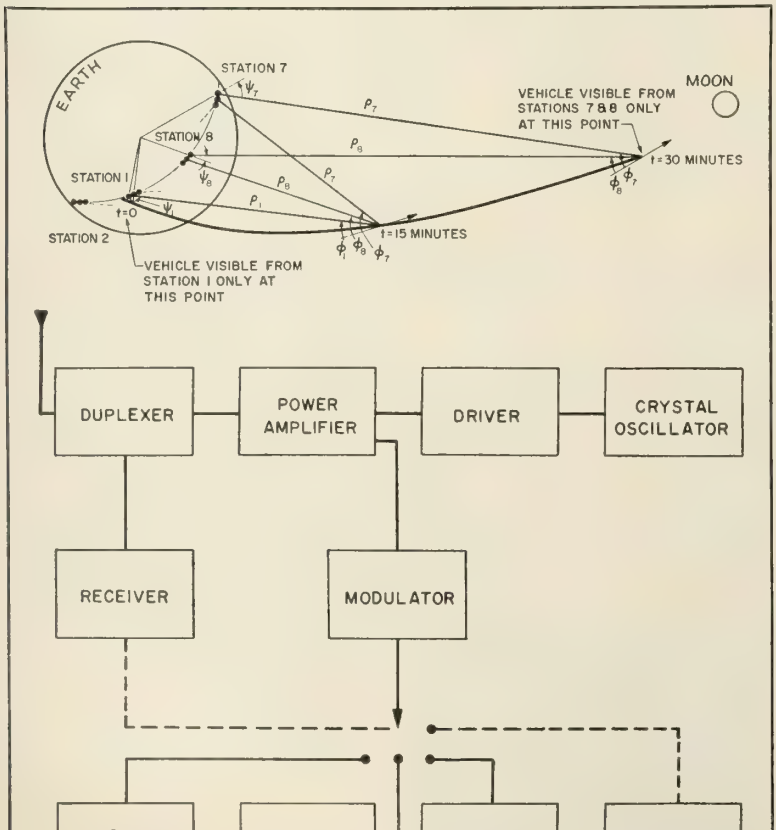
"We define our program as one of exploratory research. This is research with a view toward adding to man's total knowledge, in our case in areas of Air Force interest. Exploratory research provides 'capabilities'—capabilities for developing new concepts of weapon systems that may revolutionize the art and science of aerial warfare. In the Air Force Office of Scientific Research, these capabilities are represented by some 250 laboratories spread throughout the worldwide scientific community.

"We are concerned with three Air Forces," General Gregory said. "First, the Air Force of today, next the Air Force of tomorrow or the next five to ten years, and, finally, 'the Air Force of after tomorrow,' which might well be operating space vehicles rather than B-52s. AFOSR is particularly concerned with this Air Force. It is quite conceivable that the nation which controls the space around our globe will control the peace on the globe."

"So, consequently," General Gregory continued, "information about space, that is, a scientific understanding of cosmic rays, ionization, temperatures, densities in space, is of the utmost importance to us. We must understand the natural laws that will dictate tomorrow's defense. Man is climbing higher and higher, and it seems probable that a system of man-made satellites—coupled with the moon—could well become the necessary weapons system needed to tell the other fellow to keep peace, or else . . .

Air Force To Stay Ahead Of Requirements At All Times

"This thing of sending rockets to the moon is a natural result of current research in the field of advanced studies of weaponry as well as investigation of the natural laws and challenges that we must pursue and understand . . . and don't forget: we have to stay ahead of requirements at all times, and our Air Force must have the very best at all times . . . instead of trying to catch up when we learn that the other fellow already has achieved something big," the general said.



"There are several moon rocket study contracts in the works," General Gregory disclosed, "and it is quite possible that we may make some headway here when the first ICBMs become 'operational,' that is, when components such as the engines are tested and are ready to go. After all, it seems logical that the Air Force, when the ICBMs become operational, will want to train their launching crews and test their vehicles under realistic conditions—and a good way to do it might well be to send modified versions of these vehicles into orbits around the moon."

Asked whether Air Force lunar rockets will be designed to land on the moon General Gregory said it is possible the first lunar rocket will be designed to go into a semi-circular orbit around the moon to obtain scientific data.

Imperative for Air Force To Keep Up With The Russians

"This feat might well be accomplished within the next five years," he predicted. "And when I say five years I probably am quite conservative. Furthermore, several moon rocket study contracts have been in the works for some time now, and we visualize that it won't take too long before we can activate a lunar rocket program. It certainly is imperative that we keep up with the Russians in this respect since we know that they understand fully the concept of space operations and are extremely interested in space flight."

Says one rocket engineer: "The Air Force Office of Scientific Research certainly should be commended for its foresight and its interest in what may turn out to become man's greatest scientific adventure." *(See follow-up article on the moon rockets on page 82).*

Rand Corporation—a non-profit organization established to conduct research work for the Air Force—has released some information from its moon rocket studies. Top drawing shows flight path of small instrument-carrying rocket and location of tracking stations on Earth. Diagram illustrates proposed instrumentation for small moon rocket.

Huntsville Won't Give Up Fight for Jupiter

HUNTSVILLE, Ala.—News of the successful firing of the Jupiter IRBM ushered in the month of March in this old Southern city that finds itself the center of the Air Force-Army controversy—and the calendar found most of the inhabitants acting like lions.

The whole argument between the services as to the merits of the *Jupiter* and the *Thor* has been simmering throughout the community since Secretary Wilson issued his now-famous memorandum of Nov. 26th assigning responsibility to the Air Force for all missiles with a range of more than 200 miles. But little has been said publicly about it until now. Now, the lid is off.

"Charlie Wilson has put his foot in his mouth again—and this time I hope he chokes on it," declared the usually amiable editor of the *Huntsville Times*, the city's only daily. He was reacting to the statements of the Secretary earlier in the week regarding the "cancellation" of the *Jupiter* project. The "misinterpretations" and "clarifications" of his statements about the *Jupiter* and the *Thor* served only to raise the community's boiling point even higher.

There were reports that talent scouts from unnamed industries were seeking to lure away various members of the famous von Braun team of some 125 missile and rocket research scientists. Dr. von Braun himself, who is already under contract to Walt Disney in addition to other duties, was reported in a restive mood—but a check with him and with several of his associates brought the response that they were happy in Huntsville, that they had spurned many outside offers and that, income tax considerations being what they are, they would prefer to stay. However, as one put it: "We'd really like to go to the moon instead of aiming at puny targets 200 miles away."

The surging anxiety of the community was somewhat calmed by the assurances of Maj. Gen. John B. Medaris, commander of the Army Ballistic Missile Agency, that there would be no appreciable slackening of activity at the ABMA in the foreseeable future. Hiring at the Arsenal and ABMA continues unabated, and applications average 1,200 a month.

Meantime, the case of Col. John C. Nickerson became entangled in the hot discussions of Secretary Wilson's various remarks.

The community has stared with wide-eyed awe at the spectacle of the Colonel being escorted through town by armed guards when he comes in from the Arsenal to visit his attorneys.

As Secretary Wilson's latest press conference remarks were published here, there arrived on the desks of various community leaders registered letters from Army Secretary Brucker. The gist of these communications was that the Army's intelligence service had reported that these individuals had received copies of the noted brochure, "Considerations on the Wilson Memorandum" which was circulated to civic leaders and Senators and Congressman shortly after Wilson's memorandum of Nov. 26. Mr. Brucker asked that such copies as remained in circulation be returned to him or that he be given assurances that they had been destroyed. He referred to the brochure that Col. Nickerson is supposed to have released to "unauthorized persons."

Then on Feb. 28th arrived the vanguard of what bids fair to be one of the largest gatherings of nationally known newsmen to assemble in the South in some time. Their purpose was to find out when and where the court-martial of Col. Nickerson would be held and what the defense might be.

The next day, a Friday, two *Jupiters* were launched from Patrick AFB and on the Monday following, Third Army Headquarters announced its decision to go ahead with Col. Nickerson's court martial, probably in early April. In Huntsville there is widespread speculation that the case may not only develop into something like the Billy Mitchell case but provide as great a journalistic circus for the South as the Scopes monkey trial in nearby Dayton, Tenn.

The Colonel's civilian counsel will be Robert K. (Buster) Bell, of the Huntsville law firm of Bell, Morring & Richardson. Mr. Bell during World War II was top assistant to the late Brig. Gen. Edward Betts, also of Huntsville, who was chief legal officer to Lt. Gen. J. C. H. Lee of the Army Service Corps in the European Theatre of Operations. Mr. Bell in 1950 conducted a spirited campaign for Governor of Alabama and is noted throughout the state for his sharp legal acumen, biting wit and verbal resourcefulness.

With its phenomenal growth of the past six years threatened—from 16,000 to 60,000 population under the impact of the Arsenal and ABMA—the town has reacted in a manner understandable only to students of Southern psychology. A cotton mill with five modern steel and concrete buildings and an area of 800,000 square feet, plus a huge parking lot, became vacant when the Northern absentee landlord decided to sell off the machinery. Some 700 textile workers were laid off. Within the space of a week, 30 Huntsville citizens raised enough cash to purchase the property which is insured for $3,500,000. They are now offering this space to industries interested in the climatic, labor, water, TVA power and other advantages of the area.

The Army Guided Missile School, often overlooked here and elsewhere, will continue to train all the thousands upon thousands of officers and enlisted technicians who will be required as the nation takes the giant step from manned to unmanned defense. That may be ten years in the making, but 153 year-old Huntsville, the first capital of Alabama, can wait. It's betting most alert firms now engaged in aeronautics and astronautics will find it advantageous in terms of enlightened self-interest to arise and come to Huntsville.

A local wag consulting his almanac the day *Jupiter* flew read under March: "*Jupiter* will rise . . . in opposition."

NIKE HERCULES, Army's atom-loaded ground-to-air missile now undergoing final tests. Within the year NIKE HERCULES will begin to be integrated into the NIKE AJAX bases that now ring many major American cities. Note NIKE HERCULES' larger warhead and heavier boosters. It is claimed to be faster and higher than its predecessor.

Link Simulators — rehearsal for reality

The Martin TM-61 Matador, deadly ground-to-ground tactical missile of the USAF, already is standing guard over Free Europe's Eastern frontiers. And with the help of a Link radar signal simulator for the Matador, the potent weapon soon will be controlled by the world's best-trained missile guidance crews.

The Link simulator, which the Air Force recently incorporated into its state-side training programs, serves as a "stand-in" for the expensive Matador during simulated training missions. Using their own operational missile control equipment, guidance crews can direct the make-believe Matador from launching to a direct hit on an "enemy" installation . . . and the simulated mission is just as realistic as an actual one.

Link simulators furnish American defense teams with today's practice that becomes tomorrow's reality — with greater economy and efficiency than ever before.

Plasma Jets Give Minutes of ICBM Reentry Heat

In Los Angeles Giannini Research Laboratories reports development of a plasma jet with temperatures of 10,000°K. Simultaneously, the University of Chicago and General Electric's Missiles and Ordnance System Department at Philadelphia jointly announce a water stabilized arc plasma flow with temperatures exceeding 14,000°K (nearly 26,000°F) and velocities up to 4,000 ft. per second. The surface temperature of the sun is 6,000°K.

Top picture shows Giannini Research Laboratories' 10,000°K plasma jet in operation. In the middle is General Electric's water stabilized arc plasma flow producer, prior to test. Bottom: A nose cone model under test in GE unit glows white hot as it is bathed with atomic vapor at temperatures over 14,000°K.

Working with an input power of 3,000 kilowatts the stabilized arc has developed a heat transfer rate of 2,000 BTU per square foot per second about four diameters from the nozzle. This compares to 800 BTU obtained from rocket engine nozzles.

Both the GE and Giannini devices can be run continuously for minutes at a time.

Developed under the direction of Dr. T. R. Hogness, Director of the Chicago Midway Laboratories and Dr. L. Steg, Manager, MOSD Aerosciences Laboratory, the first water stabilized arc—a one-quarter inch model—was built in Chicago last July. Recently a one-and-a-quarter inch model went into operation. Present plans are to build a three-inch model which will require 8,000 KW of power. MOSD has built an evacuated test chamber for its arc in order to better control environment.

This arc is not new. Stabilized arcs go back as far as 1904 when Sweden used gas-stabilized arcs to make nitrous oxide. In 1922 H. Gerdien and A. Lotz of Siemens-Schuckertwerke, an electrical firm in Berlin, were the first to use the water-stabilized arc. Dr. Lochte-Holtgreven of the University of Kiel is a recent pioneer in the field.

The geometry used and the manner of extracting the plasma from the arc follows the experimental set-up of R. Weiss, Institute for Experimental Physics, of the University of Kiel.

Using air instead of water stabilization, plasma flow velocities in excess of Mach 10, heat transfer rates of over 6,000 BTU and still higher temperatures are anticipated.

Researchers consider that plasma jets are to heat transfer research what the shock tube is to hypersonic aerodynamic study.

Quotable Quotes from Clark, Wilson, Rickover

Every winter when Congress gets back to work and the main concern of Government Departments is once again money, the tempo of things done and said quickens. Last month Navy missile chief Rear Admiral John E. Clark set forth the Navy's missile position; Defense Secretary Wilson defined the role of scientists in his Department; and Navy nuclear propulsion head Rear Admiral H. G. Rickover demonstrated that missile engineers aren't the only ones with "that" trouble. Here, in direct quotes, are some of their words:

JOHN E. CLARK: "We can't set up launchers in great numbers . . . our launchers must be capable of rapid reloading with a minimum of readiness time . . . Missiles must be capable of stowage in large numbers in confined magazines . . . Aerodynamic engineers . . . must get the absolute maximum out of small and folding wings and the aerodynamic body of the missile . . .

"The special problems faced by the Navy in developing guided missiles for the fleet has resulted in many cases of apparent duplication in programs between the Navy and the other services. I believe that in many of these cases the charges are unfair to all concerned. It doesn't make much sense for the Army, for instance, to have imposed special Navy problems on their contractors and in the case of the Air Force to have imposed our special aircraft requirements on their contractors. As a matter of fact, while the development costs were large, each missile, apparent duplication though it might be, contributed tremendously to the art in general and each produced much that the others were able to use . . .

"Mr. Wilson's 'Roles and Missions' memorandum of November last . . . simply restated for the Navy the policy that development and operational employment of ship-based intermediate range ballistic missiles would be the sole responsibility of the United States Navy . . ."

CHARLES E. WILSON: "The difference between an engineer and a scientist is perhaps not as great as some people try to make out. There is a question of invention comes into it, also. Most scientists are a little more theoretical; perhaps have delved a little deeper into higher mathematics and written papers on various kinds of advanced things, but most engineers understand the language of scientists, whether they are scientists themselves or not. The important thing here in the Defense Department is to have somebody in this assignment who has administrative and executive ability; understands how to cooperate with other people and coordinate work. The real majority of our research work and our engineering work is done in contractors' plants; a smaller amount of it in laboratories and arsenals and places like that; plants that are operated by the services. The Defense Department, itself, has practically no activities. So that to some degree, I sense that this assignment is a misunderstood job. The responsibility of the staff in the research and engineering and of the Assistant Secretary in charge of it and his deputy is to review and audit activities, to make reports to me, when we get into controversy between the services to attempt certain standardizations to be worked out with the services to eliminate duplication and overlapping of activities; to help establish an order of importance of some of our activities and advice on troubles and difficulties that we get into. And the Assistant Secretary of Research and Engineering has no authority to operate, as such. He simply advises the Secretary what he thought up after the staff makes a study, which should be done in a particular case, and whether it is done or not is up to the Secretary, and the services and the people that do it . . ."

H. G. RICKOVER: ". . . But one factor which today most severely limits our exploitation of nuclear power is neither legal nor governmental. It is not a lack of new ideas, nor even a lack of understanding of recently developed ones . . .

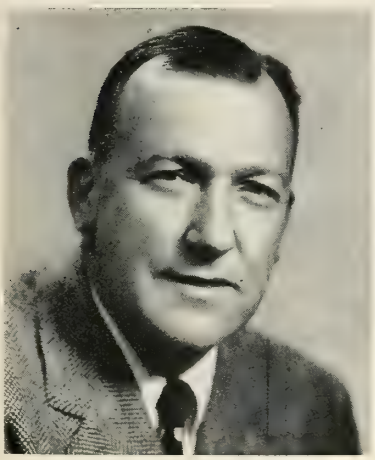
". . . New problems are being reasonably well solved . . . It has been very difficult to get sufficient effort directed toward the more conventional aspects of nuclear plants—the heat exchangers, the pumps, the valves, the instrumentation. Here normal engineering and manufacturing techniques have proved to be inadequate when applied to nuclear plants . . .

". . . Our invariable experience has been that industry cannot deliver this equipment as quickly as it is needed . . . We had expected that industry's technological know-how was sufficient to take care of these modest departures from conventional practice. We found this not to be so . . ."

RESEARCH ENGINEERS

Challenging positions are available in research and development for men with B.S. to Ph.D. degrees in Physics or Mechanical Engineering and experience or interest in the fields of rocket propulsion, ballistics, and ordnance.

We offer you an opportunity to use your initiative and creative ability in an atmosphere conducive to accomplishment. These positions afford association with some of the leading engineers in this field.



Excellent employee benefits including tuition free graduate study. Please send resume to:

U.S. Senators Due At ARS Meeting

The program for the American Rocket Society's Spring Meeting in Washington, D.C. is firmed up. Guest speaker at the banquet Saturday, April 6, will be Dr. Athelstan F. Spilhaus, Dean, Institute of Technology, University of Minnesota, and Member of the Executive Board of UNESCO. Several members of the Senate Armed Services Committee have been invited to attend.

ARS is introducing a series of sponsored breakfasts and luncheons with brief speeches and panel discussions. Among the sponsors are North American Aviation Inc., Grand Central Rocket Co., Harvey Aluminum Co., Chance-Vought Aircraft Co. and Reaction Motors, Inc. Speakers include Maj. Gen. David H. Tully, Ft. Belvoir Commanding General, discussing rocket pro-

ATHELSTAN F. SPILHAUS

pulsion and guided missiles in the atomic age, Dr. Theodore von Karman and a special panel provided by NAA.

The ARS program will include 16 papers on high-speed rocket sleds and rocket tracks. There will also be a session on Space Sociology with Dr. Wernher von Braun, Andrew G. Haley and Dr. S. Fred Singer among the speakers.

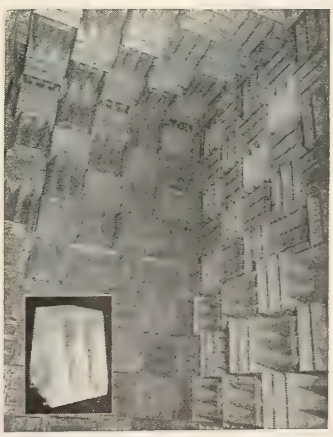
This is the first time the ARS meets in Washington, and, since it coincides with Cherry Blossom Week, many wives are expected to attend. The International Society of Aviation Writers meets simultaneously in the nation's capital.

Most significant feature of the Spring Meeting will be the Rockets and Satellite Exposition. Over 50 industry booths have already been signed in addition to exhibits by NACA, Army, Navy and Air Force.

ARS Spring Meeting Chairman, Andrew G. Haley told m/r: "We expect a record turn-out . . ." The meeting will be held at Washington's Sheraton Park Hotel April 3-6.

Russian Dogs Probe Upper Air

The Moscow newspaper Trud, February 16, described a series of rocket flights carrying dogs to an altitude of 110 kilometers. In the February 23 issue of Pomfomolfkaya Pravda more details were released wherein Professor Anatoly Bladolravo claims the Russians now know how to send men aloft in rockets. Bladolravo is Chief of the Technical Sciences Branch, Soviet Academy of Sciences.



In the first group of dog-carrying rocket flights, which reached an altitude of 100 kilometers (62.1 miles), the dogs were put in an air-tight compartment in the rocket head, containing a system of "air regeneration." Equipment carried by the rocket automatically registered the temperature and air pressure in the compartment; also took the skin temperature, respiration rate and pulse of the dogs. A camera recorded the animals' reactions. Results showed that the dogs' physical condition during the flights did not change substantially, according to Pokrovsky. There was only a small deviation from normal in the pulse rate and character of respiration. Body temperature remained almost constant, and reflexes after flight were normal.

The second series of tests reached the maximum altitude of 110 kilometers. The dogs were placed in a non-airtight compartment in the rocket head. Two catapult capsules were installed in the compartment. Inside each capsule, a dog, not wearing an oxygen mask, was placed in a special "diver-like helmet." However, an oxygen supply "sufficient to keep a dog alive in the helmet for several hours" was attached to the catapult capsule along with a parachute device and recording instruments. Weight of the capsule was about 70 kilograms (154 lbs). The parachute allowed a vertical speed of approximately 6 meters (about 19.7 ft) per second. The dogs were placed in the helmets daily for steadily-lengthened periods of time for two months preceding the rocket flights.

Launchings usually took place three to five minutes before sunrise. At the top of the trajectory, the rocket head containing two dogs separated from the body of the rocket. At a height of 80-90 kilometers, during free fall, the dog in the right capsule was catapulted. Speed of capsule ejection from the rocket head was about 700 meters (2,296 ft) per second. The parachute opened three seconds later at a height of 75-85 kilometers. "For an hour the animal was subjected to the direct effects of all external factors in the upper levels of the atmosphere."

The rocket head, freed of the right capsule, continued its rotating free fall. The second dog, located in the left capsule, was catapulted at an altitude of 35-50 kilometers at a speed of 1,000-1,500 meters per second. This free-fell to an altitude of three-four kilometers, where its parachute opened.

During the entire rocket flight, up to the moment of catapulting the capsules, a camera took pictures of the animals. According to *Trud,* some dogs made several rocket flights. It said that no animals were killed by the experiments. They were about the size of cocker spaniels.

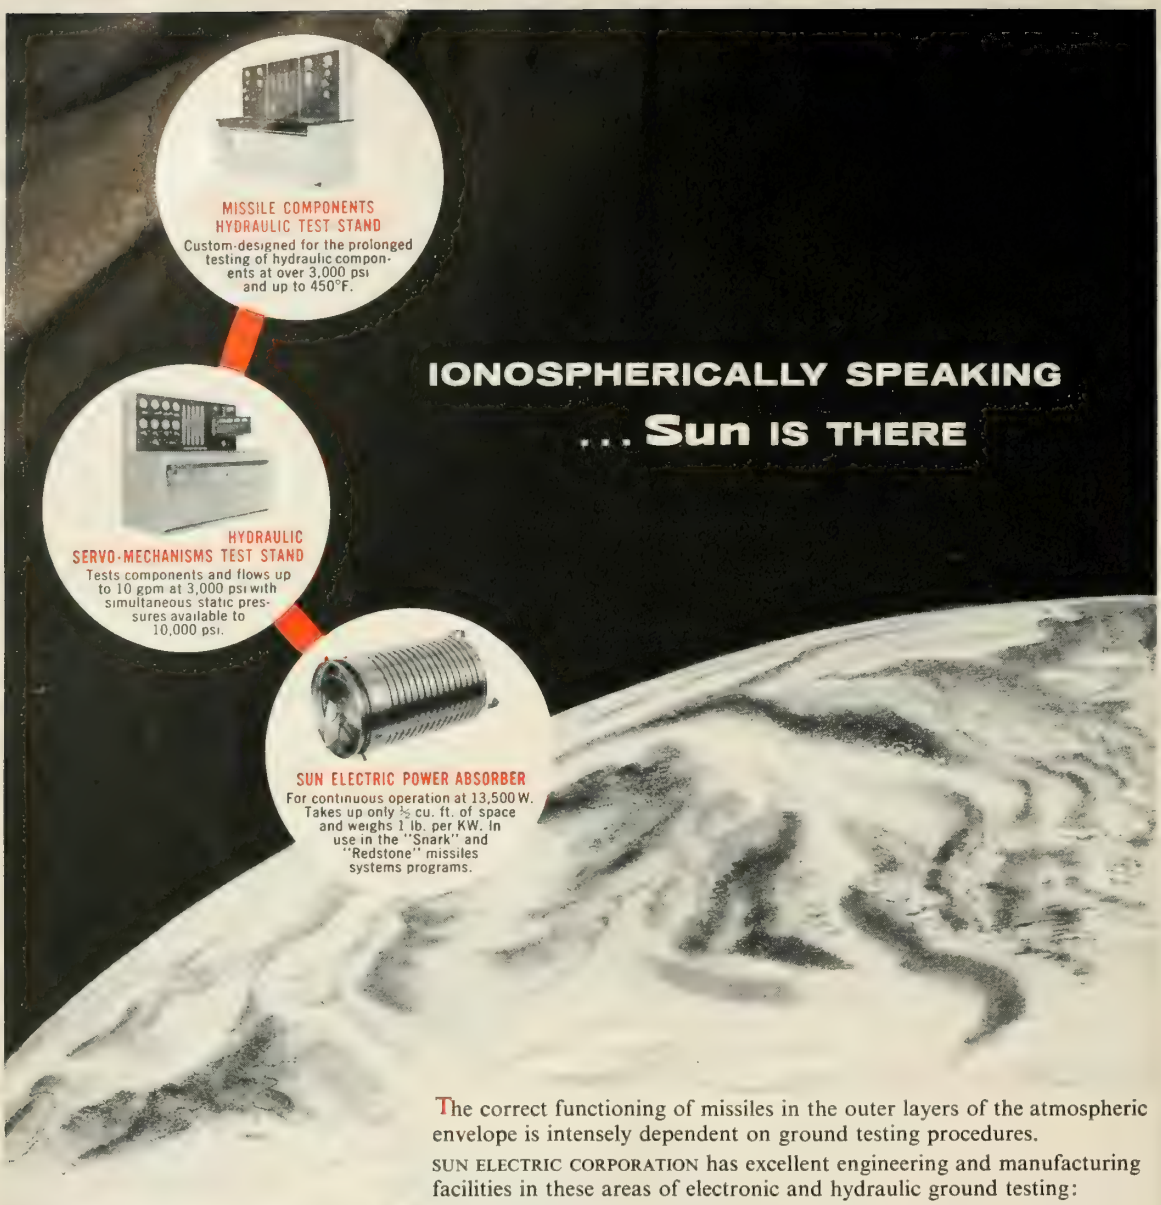
Another AN-ECK-OIC® WEDGE installation
Anechoic Chambers are recognized as valuable facilities for analyzing noise sources in automotive and aircraft engines, components, auxiliary machines, electric and audio equipment.

Recent Anechoic Chamber installations have been constructed for General Electric Co., Pittsfield, Mass., The National Bureau of Standards, Washington, D. C.



In many of the Anechoic Chambers in the United States, AN-ECK-OIC® Wedge units made by THE ECKEL CORPORATION provide the near perfect sound absorption.

For the silencing of Engine Test Cells, Firing Ranges, noisy machines and equipment consider the use of ECKOUSTIC® Sound Control Panels —product of THE ECKEL CORPORATION.

The Eckel Corporation Engineering and Installation organization can be helpful to you in solving your sound laboratory problems.

The correct functioning of missiles in the outer layers of the atmospheric envelope is intensely dependent on ground testing procedures.

SUN ELECTRIC CORPORATION has excellent engineering and manufacturing facilities in these areas of electronic and hydraulic ground testing:

—Ground support test equipment for missiles systems
—Quality control test equipment for missiles component functions
—Reliability-test equipment for the above
—Firing stand test equipment
—In-factory functional test equipment

Our staff of qualified engineers is ready to work with you to solve your testing problems.

IF CLOSE DEADLINES ARE A PROBLEM ALSO, SUN can be a great help to you. We are not bound up in red tape, we can give you fast action!

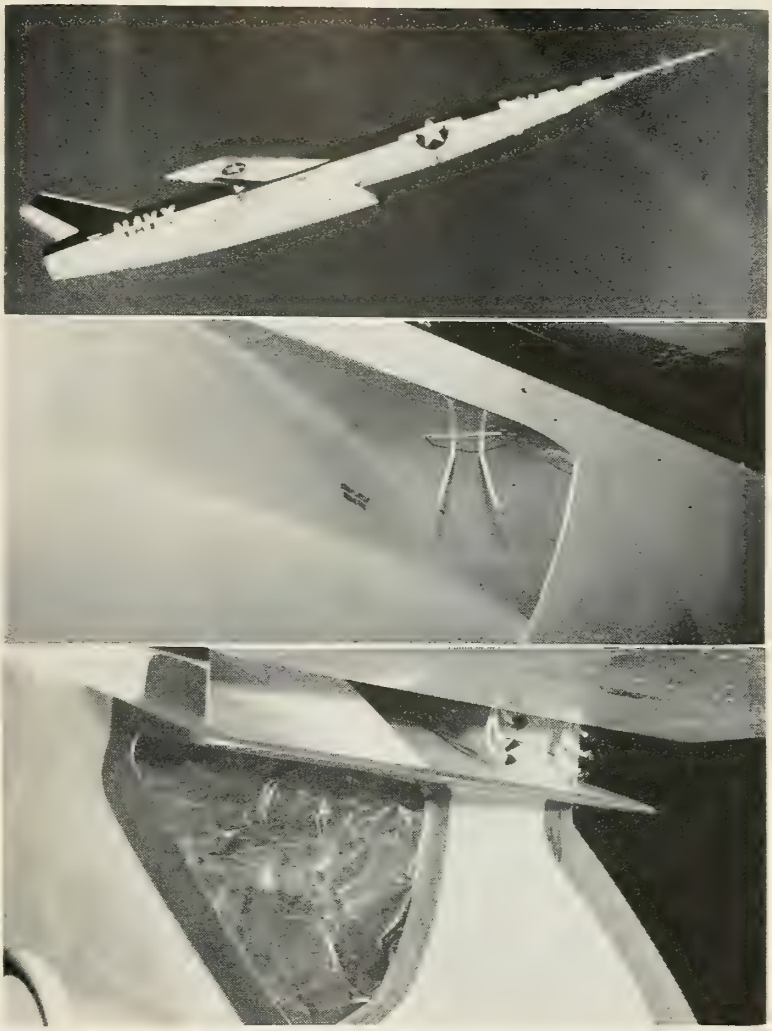
Regulus II Trainer Has Boundary Layer Control

Chance Vought's better-than-Mach 1.5 *Regulus II* made its first official public bow at the Navy League meeting this month in Washington, D.C. Though faster by far than its predecessor, *Regulus I*, the 57-foot long bird still incorporates wheels in the test and training version. It has a 20-foot wing span. Missile placed on display was number seven.

Well along in its land test program at Edwards Air Force Base, Texas, preparations are now being made to launch it at sea. It's expected that it will become operational in about a year. It will fit *Regulus I* submarine stowage and launching gear with only slight modifications.

The supersonic Chance-Vought missile incorporates many proven *Regulus I* components, such as the same Sperry auto-pilot; same beacons; and the same system for recovery.

In landing after test, *Regulus II* hits the runway at a hot 250 knots. It has no flaps; uses only a drogue parachute to slow it down. Even at this high landing speed it still requires boundary layer control for the wheeled versions. Photographs to the left show the air intake for this system. Bottom photograph shows the boundary layer exhaust duct. This will not appear on the operational missile.



Also, like its predecessor, *Regulus II* carries a nuclear warhead, either fission or fusion. It has already flown over 50,000 feet and has an all-weather range of over 500 miles. As of March 1, there had been thirteen *Regulus II* flights—six with the same missile.

While *Regulus II* was making its first public appearance, it was announced that *Regulus I* had successfully completed more than 500 flights. Also, it was reported that *Regulus I* was now being tested under near-Arctic operational conditions in the North Atlantic. In addition to being able to perform its mission from either land, surface ship or submarine, the *Regulus I* has been developed into a highly successful target drone.

Regulus II's production power plant will be the General Electric J-79 with full afterburner.

This engine is currently rated at 12,000 pounds dry thrust and 16,000 wet, which should make *Regulus II* nearly hypersonic in its final dive.

There are reliable reports that the effective range of the *Regulus* missile series may be increased to as much as 1,000 miles by the addition of podded fuel tanks.

Trainer-test version of Regulus utilizes boundary layer to enable it to make wheeled landings for full recovery. Designed as a one-way missile, it has virtually no low-speed aerodynamic characteristics, landing at 250 knots. Middle picture shows boundary layer exhaust duct. Bottom shows in-take just over main engine intake.

MASSIVE OPTICS

in the Largest Dimensions

Hayward produces massive optics for large aperture aerial camera lenses and view finders, missiles, wind tunnel lenses-mirrors-windows, Schlieren systems, radiation counters, beam splitters and special test apparatus. Stock castings 6 feet x 1½ feet x ½ foot; facilities for round, square or rectangular castings up to 60 inches. *For assistance, present us your problems.*

Rocket Trends

By Erik Bergaust

Convair did an outstanding job on its space flight symposium co-sponsored by AFOSR in San Diego last month. This is the kind of thing the American Rocket Society should have undertaken long ago. "We ought to have these symposiums at least once a year," AFOSR Brig. Gen. Hollingsworth Gregory told this writer. The symposium was attended by more than 500 engineers and scientists. It was the first of its kind, and it was successful, indeed. Congratulations to Convair's Dick Gottschall and the entire PR staff for the fine way they handled press relations; they went all out to help newsmen get the right kind of story across to the public about these highly scientific subjects. Several companies said they would consider taking on next year's symposium. By the way, the first symposium was a punchy inauguration for the Air Force in its *psychology campaign* for justification of the forthcoming space flight programs.

Lockheed is pushing the X-17 real hard. During our quick tour of the Los Angeles missile boom area, we were told the X-17 is "a most successful test vehicle." In fact, we learned reliably that Lockheed has proposed a new *weapons system based on the X-17*. The monster can zoom to 300 miles straight up if desired. However, the three-stage missile is designed to topple over. Re-entry then becomes a *powered downward flight* of Mach 15 velocity. Lockheed's missile group has several missile proposals in the works. Among others, the company is understood to have prepared a couple of space flight proposals. The Air Force reconnaissance satellite remains a mystery, and Lockheed officials cannot say a thing about it. Said one AF official: "That kind of satellite will become part of a gigantic future weapons system." Other than the fact that the reconnaissance satellite is being planned, the project is hush-hush.

Northrop is justifiably proud of its Mark I guidance system for the *Snark*. Within security limits this reporter was given the opportunity to watch the production phase of the all-Northrop inertial system. *Snark* production—in general—is getting underway at an accelerated rate, indicating General Curtis LeMay wants his long-range missiles as soon as possible. (He could have had them two years ago if the Air Force had been somewhat more enthusiastic in carrying out its long-range missile program.) Northrop can't tell you how many successful *Snark* flights they've logged, but they are numerous. Of course, you don't hear about the successful ones . . . Northrop also showed this writer a new 7-minute *Snark* movie—quite spectacular —that will be made available soon to interested groups. Company officials couldn't confirm that Northrop is working on a super-duper missile. But one Northrop scientist said: "We would be off our rocker if we weren't looking ahead for new challenges."

Grand Central Rocket will hire another 100 engineers this year. Expansion is in full swing and *Dart* powerplant production (plus two classified missiles) is in the undertaking. A low-and-slow sightseeing trip by light plane over the company's newly acquired 8,000 acre test site in the remote Riverside County area revealed a million-pound thrust cell—the first of many. Says technical director Frank Marion: "We will compete with the liquid boys soon—*20% more specific impulse and 5% better density is what we need.* And we're working hard to achieve it. We'll do it." The company has all kinds of projects in the mill and are submitting frequent proposals. *Vanguard* third-stage engine tests are routine now, numerous successful firings having been conducted. Grand Central's Bob White will be out killing rattlesnakes again this spring, because the company's noisy engine tests fail to scare the diamondbacks away.

Model GLH

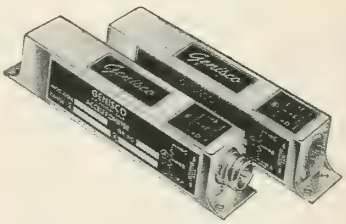
A rugged magnetically damped instrument with low natural frequencies for low range. High-quantity production assures good price and delivery schedules. Available in ranges from ±1 G to ±30 G.

Model DDL

Magnetically damped low-range instrument available in ranges from ±1 G to ±30 G. Ultra-sensitive models supplied as low as ±0.1 G. Certified to MIL-E-5400 and MIL-E-5272A. Especially good in severe shock and vibration applications. An acceleration-sensitive switch version of the DDL is designated as the Model DDS.

Model GAL

Incorporates a variable transformer a-c output with the magnetically damped sensory mechanism of the proven Models DDL and GLH. Superior reliability, life, resolution, and sensitivity. Available in ranges from ±1 G to ±30 G. Range as low as ±0.1 G also obtainable.



Model GMO

A rugged, miniature, viscous-damped instrument with ranges from ±2 G to ±30 G. Unbalanced-range instruments also available. Medium high natural frequencies.

Model GMT

Basically a Model GMO with internal thermostat-operated heater, assuring maximum environmental stability within the instrument. Damping remains constant with change in ambient temperature.

Model GDM

Miniature double-potentiometer instrument capable of sensing lateral acceleration in two mutually perpendicular planes (e.g., pitch and yaw). Ideally suited for missile and high-speed aircraft flight control systems.

NEW! GENISCO ACCELEROMETERS NOW GOLD PLATED FOR GREATER RELIABILITY

CASES GOLD PLATED INSIDE AND OUT—This new trend in instrument plating has two important advantages over tin plating or fusing. Being the least active metal, gold prevents the formation of crystalline "whiskers" inside the case which could reduce performance and even cause malfunction. Gold plating also assures positive protection against corrosion to the exterior of the case and, because of its excellent solderability, makes possible a more reliable hermetic seal. The new gold plating is available on *all* models at *no extra cost.*

Washington Spotlight

By Henry T. Simmons

The precarious future of the *Navaho* intercontinental missile is dramatically illustrated by the fact that there are no funds for its support in the fiscal 1958 Air Force budget. The program was almost wiped out during preparation of the new budget, but was saved through some financial leger-de-main with fiscal 1957 funds. The project was re-oriented along purely research lines and a number of XSM-64 test *Navahos* were lopped off. USAF will decide in fiscal 1958 whether the project will get full support or die a quick death. Cutback forced North American to lay off 300 *Navaho* workers and re-assign another 300, but it still hopes to finish tests of the ramjet-powered prototype on schedule.

•

This view of the cutback may sound like rank optimism, but it rests on some important considerations. The XSM-64, for example, is equipped with landing gear and is theoretically recoverable with a dead-stick landing procedure developed on its predecessor, the turbine-powered X-10. Judging from the good results with the X-10 (Number One was fired 11 times before plunging into the sea), a smaller number of "X" *Navahos* will suffice for the test program. Perhaps more important, the SM-64A production version now in the design stage incorporates so many improvements over the test model that the original elaborate program is no longer deemed necessary.

•

Attempts to launch the XSM-64 got under way at Patrick AFB, Fla., late last year, but as this is written, the Air Force is still looking for its first successful firing. The initial try in December came to grief when the huge missile reached 9,000 feet; a rate control gyro malfunctioned and the test was aborted. Later efforts were plagued with range difficulties. On one occasion, a freighter wandered into the booster dump zone off Cape Canaveral; by the time the count-down could be resumed, a down-range tracking station broke down and the test had to be canceled. Although these troubles suggest the *Navaho* will prove at least as cantankerous to develop as any other advanced weapon system, its supporters insist that the new bob-tailed program still allows for such setbacks.

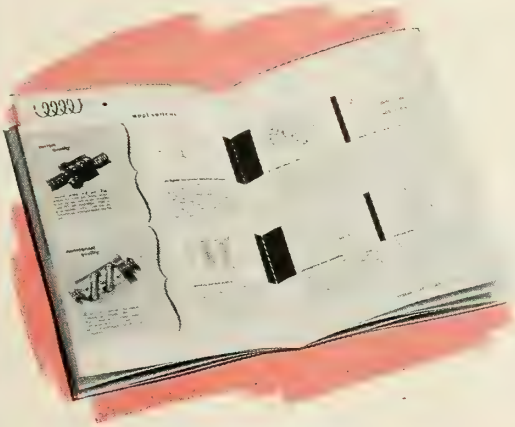
•

Latest explanation of the testing troubles of another Air Force missile, the *Thor,* blames the January launching stand explosion on foreign matter which was allowed to contaminate the fuel. If so, the hardware of the IRBM—including the North American engine—is absolved of guilt in connection with the mishap.

•

Future Navy interceptors may carry mixed loads of missiles—one radar *Sparrow* and one infra-red *Sidewinder.* Latter weapon is immune to countermeasures, but can't be used in rain or heavy clouds while the former is an all-weather weapon. Hughes is developing an infra-red *Falcon,* indicating USAF may follow this approach.

•



The new air-to-air rocket with the nuclear warhead which Defense Secretary Charles Wilson announced last month is the Douglas *MB-1,* a liquid-propellant missile now in operation with the Air Defense Command. It used to be called the *Ding Dong,* but disgruntled USAF security officers changed it to *High Card* when it leaked out. The second name also leaked, so the weapon was given its present inglorious moniker. The Northrop F-89J and the Convair F-102 and F-106 will carry the new weapon, later versions of which will use a solid-propellant motor.

FREE! YOUR NEW ACTUATOR and SPLINE "PROBLEM SOLVER"!

New 1957 Engineering Data Book from World's Largest Producers of Ball/Bearing Screws and Splines

36 pages crammed with time-, work-, and money-saving facts: Principles • Types • Basic Operations • Coupling Methods • Efficiency • Versatility • Advantages • Selection Factors • Design Data • Sample Problems, etc.

SAGINAW b/b SCREWS are *90%-98% efficient* (compared to 15%-20% efficiency of Acme screws). Require ⅔ LESS torque and power for same linear output—with consequent weight, space reductions. Function normally at −75° to +250° F. Two types: precision-ground or commercial rolled-thread. Have been built 1½ in. to 39½ ft. long.

SAGINAW b/b SPLINES have *40 times lower coefficient of friction* than sliding splines; transmit or restrain high torque loads far better; permit vital power, weight, space reductions. Have been designed 3 in. to 10 ft. long.

MAGAZINE OF WORLD ASTRONAUTICS

m/r exclusive:

1957 Research Rocket Roundup

The first sustained use of the rocket vehicle for upper atmosphere research followed the close of World War II, when some 100 of these rockets were brought over to the U.S. At that time V-2's were available in considerable quantity. By early 1946 the Upper Atmosphere Research Panel had been established. The name was changed in 1948 to the Upper Atmosphere Rocket Research Panel. Its members included top scientists concerned with upper air research from Evans Signal Laboratory, Naval Research Laboratory, Air Force Cambridge Research Center, etc., as well as universities, observatories, and private companies.

U.S. scientists and military firing crews launched the first V-2 in the U.S. on April 16, 1946. On June 28 the first completely instrumented, high-altitude research V-2 took off from the White Sands Proving Grounds. One was launched from the U.S. aircraft carrier Midway in late 1947.

General Electric Co.'s Project Hermes fired the most research V-2's, gaining great experience from the German scientists who worked in this country after the war and from translated German reports. Army Ordnance was the cognizant military agency.

Standard and Modified V-2's

The standard V-2 warhead had about 16 cubic feet of space available for instrumentation. In a number of V-2's redesigned by the USAF, instrumentation space was increased to 80 cubic feet, increasing the rocket length about five feet, increasing the length from 524 to 589 inches. However, the V-2 still had disadvantages. It was an old missile. Many parts were unreliable and had to be rebuilt. It was much too big. For stability reasons, its full one-ton payload had to be carried, and because a ton of instruments cannot be crammed into such a small space, useless ballast had to be added.

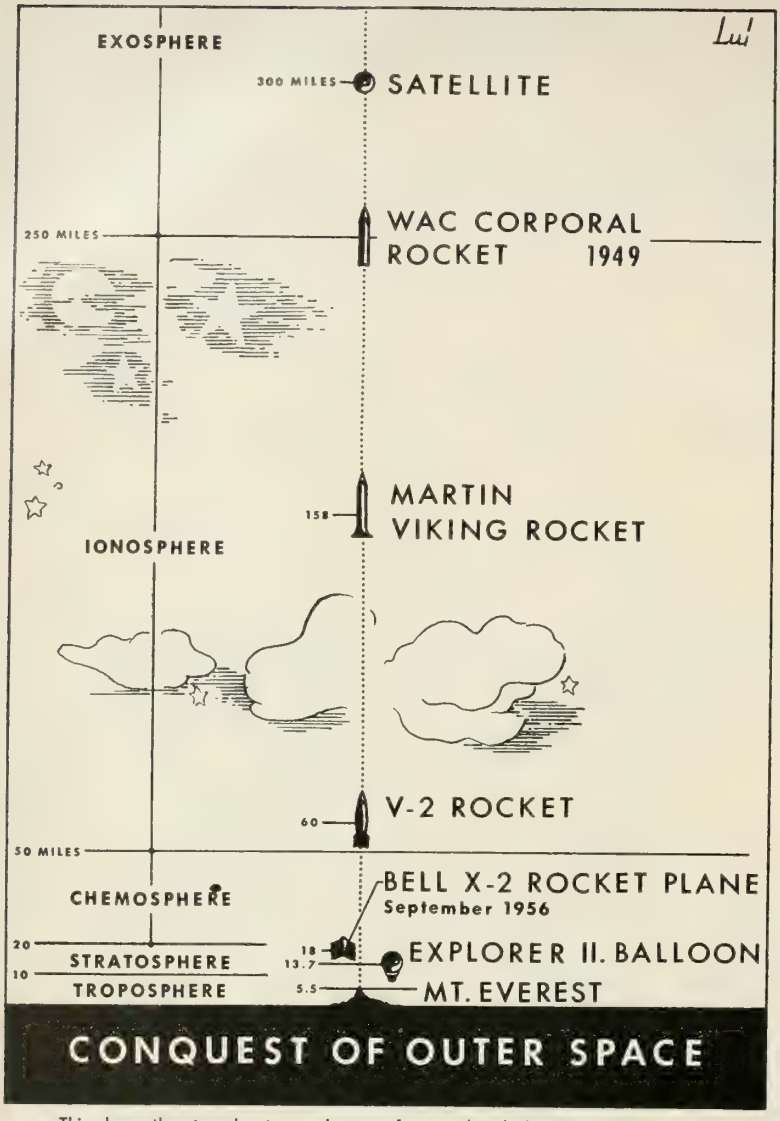
In general, the use of military missiles for research is not particularly attractive. But the V-2 was available, and it launched a very important and sustained U.S. research program.

Of the 70 odd V-2 firings undertaken by the U.S. about 75% were considered successful, meaning they hit altitudes of 50 miles or more.

Staging Sets Record

An important step in the program was the mating of the V-2 with a small American WAC-*Corporal*. A series of these *Bumpers* were fired, including one that broke all altitude records and another that broke the atmospheric velocity record. Most of them were fired from White Sands Proving Ground, but two were launched from the Patrick Air Force Base Missile Test Center in Florida in an attempt to gain maximum range and velocity. The fifth *Bumper* rocket, fired from New Mexico, hit over 5,000 miles per hour, and the small WAC-*Corporal* reached a peak top altitude of 244 miles. This world's record was only recently broken by a three-stage rocket using a *Redstone* missile as the first stage and modified *Sergeants* (or *Recruits)* as second and third stages. These early *Bumper* flights taught scientists how to: communicate beyond the ionosphere; work with staging problems; ignite motors at extreme altitudes.

By July 1, 1951 Project Hermes ended, a success. Under Hermes, the peak altitude gained was 116 miles. There were also a number of test firings made by White Sands personnel and other agencies. One of these, an uninstrumented rocket launched in late October, 1951, reached 132.5 miles.



m/r presents herewith what it believes to be the most complete roundup of the history and specifications of research rockets ever compiled at one time. The research rocket is a peaceful vehicle. The data it gathers pioneers man's approach to outer space. Frederick I. Ordway III and Ronald C. Wakeford, who are to be congratulated for authoring this roundup, are President and Research Engineer, respectively, of General Astronautics Corp.

America Makes Its Own Rockets

About 1930 the Daniel Guggenheim Foundation provided Dr. Robert H. Goddard with the grant that gave U.S. rocket research its start. At California Institute of Technology's Guggenheim Aeronautical Foundation, a group of rocket researchers worked into the late 1930's. At the same time, on the east coast, the American Rocket Society was performing its research work and later a group of experimenters at the U.S. Naval Academy also did rocket research.

During the war at Cal. Tech's Jet Propulsion Laboratory the first sustained government supported rocket research began. This led directly to the development of research rockets. One of the first steps was the *Private A* rocket and later the *Private F*. These small, fixed-finned rockets were launched from steel booms about 36 ft. long, ascending on four guide rails and were boosted during their travel in the small steel guide booms. Many tests were made during 1944-45 at Barstow, California, and later at Ft. Bliss in Texas.

The group that designed and developed these rockets was called ORDCIT—Ordnance Contract to the California Institute of Technology. They were asked to develop a sounding

This shows the stage-by-stage advance of research vehicles towards free space. The JUPITER-C, of course, with a record altitude of 680 miles, is off the chart.

rocket to carry a small 25 pound payload up to, perhaps, 20 miles. They built the *Baby*-WAC, which was test fired during July, 1945, at the California Goldstone Range. It was a one-fifth scale model of the 16 foot long, 665 pound WAC-*Corporal* that was later developed from it.

The first firing of the WAC-*Corporal* was on September 26, 1945, at the White Sands Proving Grounds, some six months before the first V-2 launching in the U.S.

Aerobees and Aerobee-Hi's

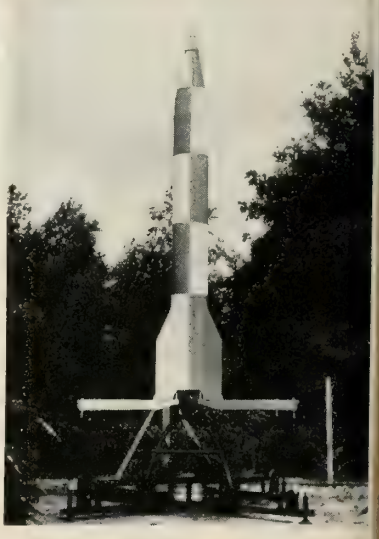
While the V-2 was too big, the WAC-*Corporal* was too small for many research purposes. This led to the first specifically designed upper air research vehicle, the *Aerobee*, developed by the Applied Physics Laboratory of Johns Hopkins University and the Aerojet Engineering Corp.

Most of these *Aerobees* have been built by the Douglas Aircraft Co. The first *Aerobee* contract was let in 1946 by the Navy Bureau of Ordnance in close cooperation with the Office of Naval Research. The preliminary order for 20 was later considerably increased.

Other services, such as USAF, have also ordered *Aerobees*. The first full firing occurred (dummy missiles had been booster-launched earlier) in November of 1947. By 1948 an *Aerobee* had reached 70 miles, and somewhat later another soared 100 miles. Like the V-2, they also have been launched from shipboard.

A variation of the *Aerobee*, the *Aerobee-Hi*, was developed and by 1955 it reached 124 miles. Later, the world's single-stage altitude record was broken by a 164 mile flight.

Aerobees have been used by all services and are most versatile and successful. Up to last summer some 150 had been launched, with 128 operationally successful. They were fired as follows: Johns Hopkins University, 17; U.S. Army Signal Corps, 33; U.S. Navy, 35; U.S. Air Force, 65.



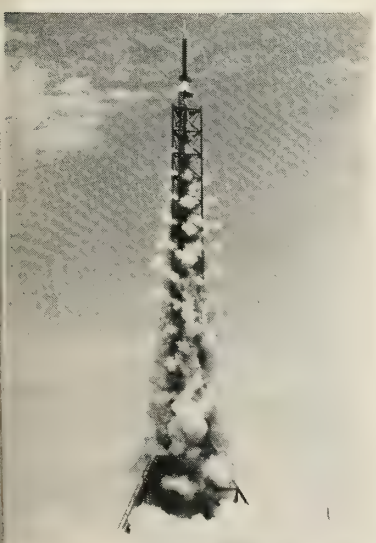
More than 50 *Aerobees* will be fired from Ft. Churchill and Holloman during the International Geophysical Year. Experiments will include free-electron density studies, ultra-violet radiation, cosmic ray, Lyman-alpha and day brightness investigations, and research on the existence and density of interplanetary matter to 200 miles.

Air Force Program

In 1952 the Air Force negotiated a contract with Aerojet to improve the *Aerobee*. Two basic improvements were made: 1) The propellant tanks were enlarged to handle 32 per cent more fuel and oxidizer; and 2) these tanks were made of lighter 410 stainless steel. This improved the mass ratio from 3.17 to 4.62. On its first flight in April, 1955, with a payload of 196 pounds, it soared to 124 miles.

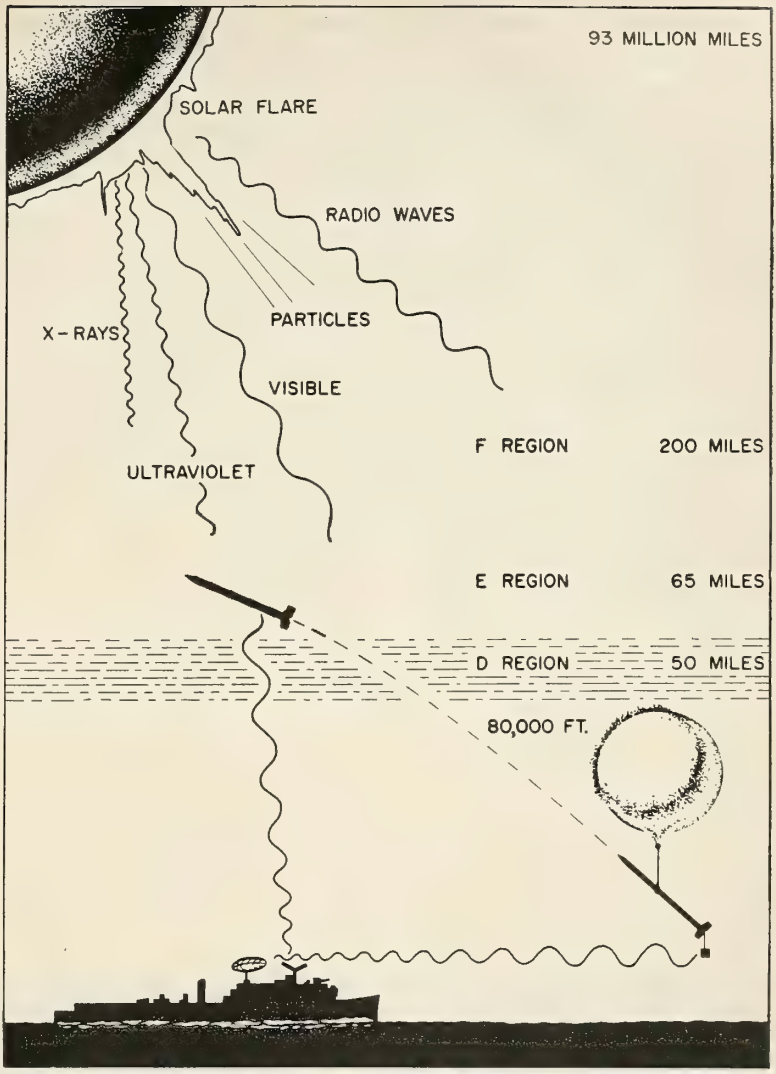
Navy Program

Because of a desire to get into the F region of the ionosphere the Navy program called for the thrust chamber as well as the overall rocket to be completely pressure-sealed. This would eliminate the danger of escaping gas



Veronique, star of France's missile effort, was developed under the Ministry of Defense. The vehicle hits 3200 mph, carries 133 lb. payload.

from contaminating the ambient conditions and thereby invalidating upper air experiments. Not only did the Navy use the AF's improved steel tank material but it further increased the propellant capacity of the vehicle, improved the thrust chamber assembly, and of course, the mass ratio. A chemical gas generator replaced the helium tank.



Due to the lack of time and the urgencies of the IGY, the development efforts of the chemical pressurization system will be suspended, and Navy *Aerobee-Hi* rockets will use helium pressurization techniques during the next few years. However, a better acid appears to be on the way as well as an uncooled combustion chamber.

The basic aim of this program is to reach 180 miles with a 150 pound payload. In pre-IGY tests at Fort Churchill, Canada, additional RT-N-13B's were successfully fired, as well as a RV-N-13C which carried 156 pounds to 157 miles. The Air Force Model AJ-11-6 carries a 150 pound payload to about 140 miles, and, due to different launching conditions, to 165 miles at White Sands Proving Ground. The Navy RV-N-13B carries its 150 pound payload to 147 miles; to 162 miles if launched from White Sands. If the payload is lowered to 120 pounds both these missiles should gain another 17 miles under sea level launch conditions and an Arctic atmosphere.

According to Townsend (in an American Rocket Society Annual Meeting lecture), when the Navy *Aerobee* changes its tanks to the new type it should gain another 10 miles. Eventually both the Air Force and the Navy

The 4,435 mph AEROBEE-HI shoots from its launcher at White Sands Proving Ground, N. M. is used for ionosphere research.

Artist's sketch of ROCKOON, 68-foot diameter plastic balloon and a 12-foot solid propellant DEACON sounding rocket at they will perform during the IGY.

models will probably use a ceramic lined thrust chamber (such a chamber is now under development, to deliver 5,000 pounds of thrust). A Navy *Aerobee-Hi* should reach 167 miles with a 150 pound payload under Arctic atmosphere and sea level launch conditions. If this chamber is used with a 120 pound payload, a 188 miles altitude would be possible and if fired at White Sands, an additional 15 miles.

Vikings Replace V-2's

Going back to 1946, and picking up the thread from the East Coast companies, we find the *Viking* program underway. At NRL plans had been hatching for some time to develop and build a fairly large U.S. rocket vehicle capable of replacing V-2. It was apparent that the supply of V-2's in the United States would not last forever and that if the U.S. wanted large rocket missiles when this supply was exhausted, it would have to begin work immediately. NRL contracted with the Glenn L. Martin Co. in August, 1946, for 10 large rocket vehicles. Later this was upped by four additional missiles. The powerplant award contract went to Reaction Motors, Inc., organized in 1941 by a group of American Rocket Society experimenters. First called the *Neptune,* the name was changed to the *Viking* so as not to confuse it with the Navy *Neptune* airplane. Until recently the 158 mile altitude reached by a *Viking* was the world's record.

Vikings have undergone continued change during the overall development program. The first seven were relatively similar, as are the latter series. For example, the earlier *Vikings* were more

than 48 feet high; the later *Vikings* were less than 42 feet. This can be compared with the 46 foot V-2. The first series were only 2 feet, 8 inches in diameter, the second series nearly 4 feet. Compared with the nearly 5½ foot V-2 rocket, both missiles are slim. The thrust generated by the *Viking* rockets ranges from 20,000 to 21,500 pounds, compared to the 56,000 to 60,000 pounds of the V-2. The rockets weighed anywhere from a little under 10,000 to a little under 16,000 pounds, which again compares with the much heavier German vehicle.

Some element of success attended all the *Viking* firings with the exception of No. 8, which broke away in a static test.

The payload of missiles has changed a lot in recent years. Formerly, it was common to carry on a fairly wide variety of experiments from one vehicle having payloads of many hundreds of pounds. Today it is amazing what can be done with relatively low (25 to 50 pound) payloads. The tendency now is to use a given rocket for a given experiment. For one thing altitudes will vary depending on the experiment. Some experiments should be made near the peak of the rocket trajectory. Others can be profitably made on the upward trajectory or on the downward trajectory. If too many different experiments are made with a given rocket, damage to some of the other experiments may occur, and consequently, we find that the general philosophy of one rocket for one experiment (or at least very few experiments) is gaining favor.

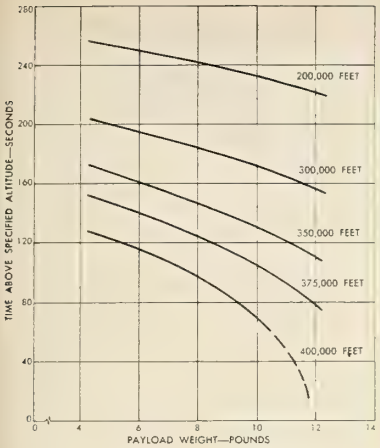
While most vehicles are being fired in a vertical or near vertical trajectory, attitude control is not always necessary. Some vehicles have to have this attitude control for certain experiments such as following the sun. Others that might want to go into a special trajectory (such as the *Vanguard* rocket when it launches the Earth satellite) require spin stabilization, and so forth.

As with the *Aerobee* rocket, the problem of contamination is very important in making atmosphere composition experiments. For example, if exuding gases from the rocket are allowed to enter the atmosphere and contaminate the sampling bottles, accurate chemical analysis is impossible. For that reason clean rockets are needed.

The recovery of data is, of course, extremely important. Biological specimens, photographs, etc., have to be directly recovered by some sort of a drogue or parachute technique, or by aerodynamic descent following separation of the nose cone from the vehicle.

It is one of the characteristics of the 1950's that all too little money is available for upper air rocket research; so it is all the more important the price be kept as low as possible. An *Aerobee*, for example, costs between $30,000 to $40,000 per rocket, somewhat less than the *Viking*. *Deacon* and *Cajun* rockets are less expensive than the *Aerobee*, a great advantage to the private companies and universities that may want to fire them. In addition to the rocket other costs include logistics, instruments, personnel, etc.

In a recent American Rocket Society paper on future sounding rockets, the *Spaerobee* was introduced, which adds a second stage to an *Aerobee* to give an altitude capability of about 350 miles. The payload would be 40 pounds. A second new vehicle is the *Aerosound* which is launched from an airplane in a vertical attitude. It would carry 40-pound payloads to perhaps 45 miles or 20 pounds to 54 miles. A two-stage *Aerosound* would fly to over 100 miles with identical payload weights.



U.S. Research Rockets — The Finer Details

Consistent with observations of changing techniques in rocket research, we find a whole new crop of small, efficient vehicles entering the pre-IGY scene. They carry such names as *Rockoon*, *Rockaire*, *DAN*, *Nike-Cajun*, *Terrapin*, *Asp*, and *Wasp* and generally cost only small fractions of *Viking* and *Areobee* rockets. Capsule information is presented on these vehicles in so far as it is now available.

One of the factors that led to the *Nike-Cajun* combination was that the *Rockoon* rocket was hard to track to

Rocket's eye view from about 100 miles up. The Navy believes this to be the largest earth area ever photographed from one spot.

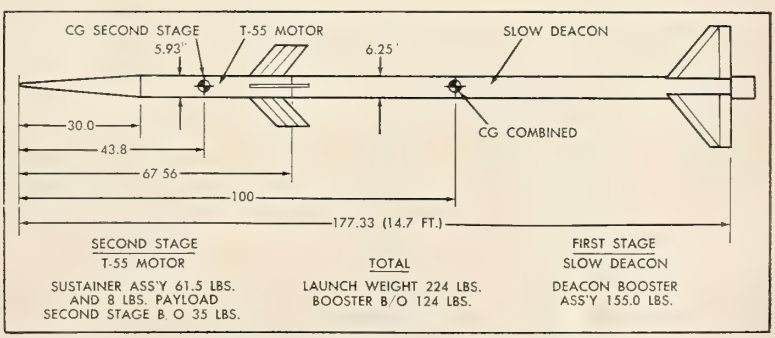
Time that Terrapin remains above specified altitude for vertical launch.

its point of impact. This was because the exact time of discharge from the balloon could not always be told, nor could the precise location of the balloon be known because of drift. In 1954 work started on providing the *Deacon* with a *Nike* booster. The aim was to bring 50 pounds up to about 75 miles. A coasting period between the exhaustion of stage one and the firing of stage two was planned. Result was the *Cajun* rocket little more than a *Deacon* with an improved solid-propellant charge. Army Ordnance supplied boosters, and instrumentation was provided by those agencies carrying out the experiments. Successful tests were made during the fall at Fort Churchill, Canada, one of which carried 100 pounds up to 70 miles.

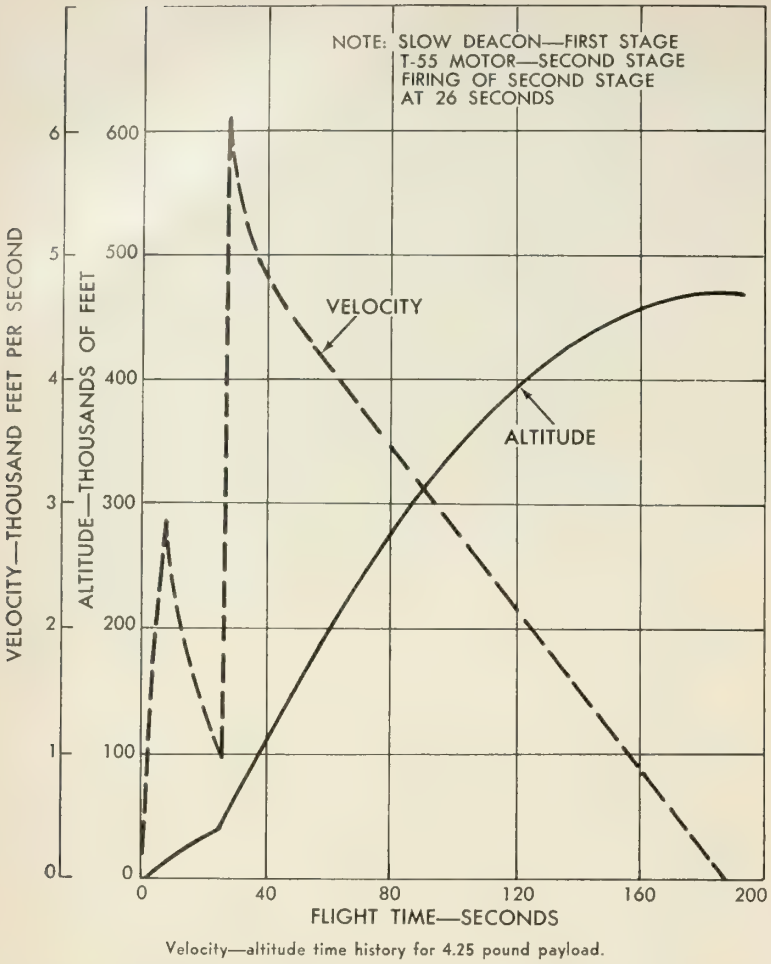
Weight, pounds 1,550
Wt. of *Cajun,* loaded, pounds ...250
Length, booster & rocket feet . . . 26
Coasting period (between separation of the rockets and firing of the top stage), seconds ..... 10 to 20
Number of *Nike-Cajuns* to be fired during IGY . . . 65 (42 will be fired from Churchill, and the rest from ships, at Guam, or at White Sands).
Record altitude for a *Nike-Cajun* . . . 95 miles (flight by the Ballistic Research Laboratories on 9 Aug. 1956. Payload was 60 pounds).
Cost . . . $4,000 (not including instruments, the booster costs an additional $3,700).

Recently four fairly successful firings of these rockets have been made. Scientists had hoped for somewhat higher altitudes than obtained.

DAN



If an unimproved *Deacon* is used, we have what is known as the *DAN* (*Deacon* and *Nike*). This program was initiated by NACA. It is obvious that



Artist's conception of an IGY satellite over a Minitrack ground station antenna array.

DAN and *Nike-Cajun* are essentially the same thing. A few figures quoted for DAN appear below:
Contractor ... NACA and U. of Mich.
Cognizant agency .....U.S.A.F., Cambridge Research Center.
Weight, booster, pounds 1,324
Weight, second stage, pounds . . . 216
Payload, pounds 10-60
Altitude, miles 70-95
Altitude, separation, feet . . . approximately 5,000
Velocity, maximum . . . . . Mach 5
Instrumentation .....Free-fall accelerometer sphere (air density measurements).

DAN has recently been replaced by the *Nike-Cajun.*

TERRAPIN Two-stage high-altitude research rocket developed by Republic Aviation Corp.

Velocity—altitude time history for 4.25 pound payload.

IRIS and ARCON

Two of the newer basic research rockets currently sponsored by the Navy are the *Iris* and *Arcon*. Both are being developed by Atlantic Research Corp. of Alexandria, Virginia. Details of the design specification indicate that the vehicles are propelled by solid fuel motors. The *Iris* rocket will have a burning time of 40 seconds and will undertake upper atmosphere experiments similar to those of the *Aerobee-Hi* (probably eventually replacing it). Preliminary information indicates that neither *Iris* nor *Arcon* will be boosted. It is expected that *Iris*, a fin stabilized vehicle, will be launched during the latter half of 1957 or early in 1958. *Arcon*, a somewhat simpler vehicle to produce, and further along than the *Iris*, is almost sure to be fired in 1957.

Data	Iris	Arcon
Diameter, inches	12	6
Length, overall, feet ..	14.83	11
Weight, pounds 1,000		250
Payload, pounds	100	40

TERRAPIN Rocket

Another in a series of small, solid propellant rockets, the *Terrapin*, was first flown late last year at NACA's Wallops Island facility. So far it has been used to make cosmic ray, temperature and rocket spin and acceleration measurements. Instrumentation includes all transistorized telemetering equipment, geiger counter and transmitter. It will be used for sustained upper atmosphere research in the 80 mile region. Several dozen rockets will probably be produced.

Contractor...Republic Aviation Corp.

Cognizant agency .....Navy Bureau of Ordnance via U. of Md.

First stage motor contractor . . . Alleghany Ballistics Laboratory—Navy Bureau of Ordnance.

Second stage motor contractor . . . Thikol Corp. with the Redstone Division of the Army Ordnance.

Vehicle type .....Two-stage

Launcher . . . Collapsible zero length

Weight, overall, pounds 224

Instrumentation, pounds 6

Length, approximate, feet 15

Diameter, inches 6¼

Velocity, maximum, mph 3,800

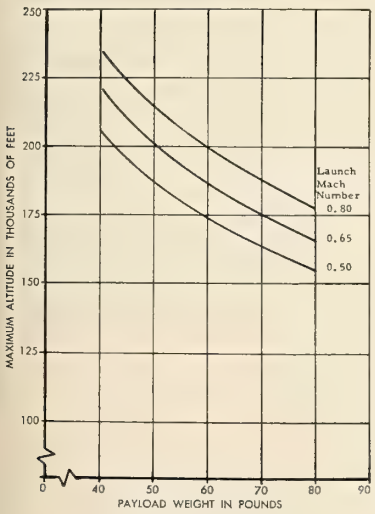
Time to impact, minutes 5.6

Altitude (first flight), miles 80

Temperature (skin), max, °F . . 1,000

Propellant .....Solid

Operational sequence: The solid propellant first stage engine carries the *Terrapin* to nearly two miles in six seconds. (Speed: 1,900 miles an hour). Then the first stage separates from the second stage, which coasts to about 7½ miles. The second stage motor now fires, bringing the missile to 9½ miles at a speed of Mach 5.8 (3,800 miles an hour). It coasts to peak.



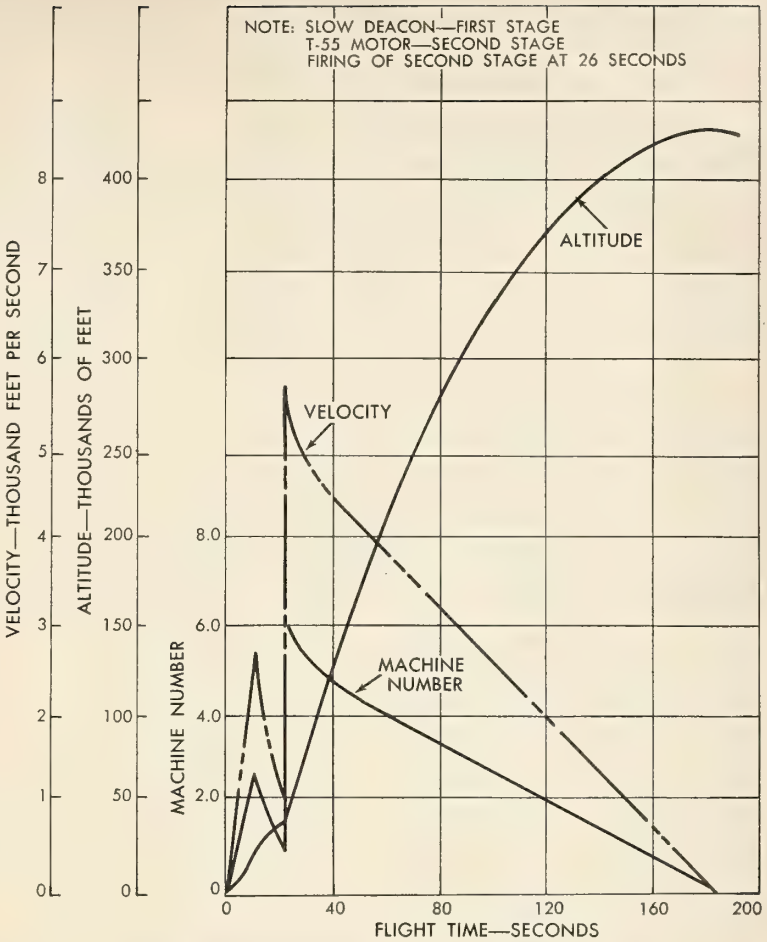
ROCKOON Missiles

The *Rockoon* system of high altitude research, begun in 1954, was the result of the Naval Research Laboratory's efforts to obtain basic data from high altitude at less cost than was possible with larger rocket vehicles.

The configuration consists of a *Deacon* rocket suspended from a 68 foot diameter plastic balloon (Skyhook). At 15 miles altitude the rocket is fired into the lower ionosphere. In July of 1956 ten such arrangements were launched to obtain information on solar flare activities. These balloon/-*Deacon* firings were supervised by Dr. H. Friedman of NRL Optics Division.

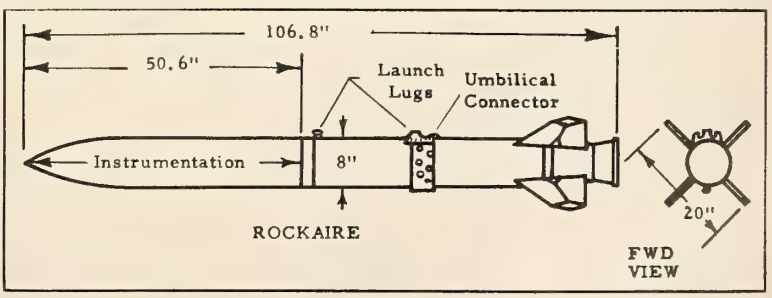
Contractor . . . Douglas Aircraft Co.
Powerplant manufacturer . . . Allegany Ballistics Laboratory.
Cognizant agency . . . U.S. Navy via State U. of Ia.
Length, feet 12.3
Diameter, inches 6.6
Weight, loaded, pounds 218
Weight, payload 20-30
Thrust, pounds 5,700-6,000
Propellant .....Solid
Altitude, miles 50-70
Guidance .....Fin stabilized
Firing time, seconds 3-3½

ROCKAIRE Missile



ROCKAIRE

This program was born of the desire to fire rocket missiles in areas other than where established large launching areas are located. The small rocket has drawbacks, particularly in its altitude capability. For example, a *Deacon* rocket could hardly get any higher than a balloon if launched from the surface. So these small rockets either have to be boosted or launched by balloon or aircraft. This *Rockaire* combination is a *Deacon* launched from an aircraft in an almost vertical attitude, for maximum height attainment. According to Air Force Cambridge Research Center's R. M. Slavin, a 40-pound payload *Deacon* gains 7,000 feet in zenith altitude for each 1,000 foot increase in launch altitude.



Principal contractor . . . . . Douglas Aircraft Company.
Typical launching technique . . . At 6 or 7 miles altitude an F-86 airplane assumes a near vertical attitude and launches the rocket.

Launching area . . . Holloman Air Development Center.

Tracking . . . The rockets will be tracked from ground stations. (Later a C-131B aircraft will carry the tracking devices as well as telemetry receiving devices).
Altitude, max. expected, miles . . . 100

Velocity—altitude—mach number time history for 8.25 pound payload.

Navy ROCKAIRE

Meanwhile, the Navy has been working on a *Rockaire* system for high altitude investigations. Instead of employing *Deacon* rockets, it has taken both the standard 2.75 inch aircraft rocket and the 5 inch HVAR and adapted them so that they could be near-vertically launched from F2H-2 fighters. One cosmic ray instrumented 2.75 inch *Rockaire* soared to a peak altitude of 34 miles. When instrumented, the nose cone is lengthened slightly by half an inch.

ROCKAIRE X113C4 Motor

Thrust .....7,800 lbs.
Burning time .....2.15 secs (60°F)
Total thrust .....15,000 lb-sec
Propellant wt .....70.3 lb.
Specific impulse .....210 sec
Launch weight (inc. 40 lb. p. l.) . . . 181.4 lbs.

2.75 Inch Rocket Data:

Period above 100,000 feet, seconds . . . 120-140

Possible Experiments:

Cosmic ray
Solar ultra-violet
Atmospheric composition
Temperatures and winds

The ASP Missile

Asp (Atmospheric Sounding Project) is employed in making meteorological, cosmic ray, and geomagnetic experiments in the upper atmosphere. Due to its high velocity it may eventually be used in hypersonic testing.

Contractor Cooper Development Corp.
Powerplant contractor . . . . . Grand Central Rocket Co.
Cognizant agency . . . Bureau of Ships, U. S. Navy (contract NObs-72000).
Program .....Operation Redwing
Length, overall, feet 144
Diameter, inches 6.5
Span, inches 20
Launching weight, pounds 245
Empty weight, pounds 95
Payload, pounds 25
Summit altitude, miles 40
Burnout velocity, mph. .....3,700-3,900 (depending on launch location).
Firing time, seconds 6
Thrust, average, pounds 5,850
Specific impulse, seconds 211
Impulse to motor weight ratio 162
Initial launch angle, degrees 30
Propellant . . . Solid 201-C (amonium perchlorate-polysulfide, rubber type).
Telemetering head . . . Consist of. a) antenna, b) insulator, c) ogive, d) thermal barrier, e) telemetering and instrumentation mounting structure.
Antenna . . . Quarter wave spike antenna threaded to 91 LD fibreglass.

Asp has been tested at Naval Air Missile Test Center, Pt. Magu, California, and Naval Ordnance Missile Test Facility, White Sands Proving Ground, New Mexico, and is fired from a monorail launcher. It is a single stage rocket with telemetry head, missile body, motor case, and fin and aft skirt assembly.

Wasp

The *Wasp*, *Asp's* small brother, is manufactured by the same company. It is an extremely light-weight vehicle, and is intended for meteorological and other scientific research at moderate altitude. Two boosters are available for use with this vehicle.

Total time to peak, with Type-2 booster, seconds 100
Altitude, maximum, miles . . . 21 with Type-1 booster ..... 28 with Type-2 booster.
Launching technique . . . Adaptable for ground or shipboard launch.
Propellant .....Solid

Instrumentation for Research

In almost all high altitude research vehicles the problem of obtaining the maximum returns for each flight is becoming increasingly important. The use of large, high-cost military vehicles for this research has been abandoned, and since the newer rockets have limited payloads, instrumentation is becoming a one experiment proposition.

In determining the physical conditions of the upper atmosphere, a multitude of experiments have been conducted. These include studies with mammals and insects, wind at altitude, pressure, density and temperature measurements, upper air sampling, etc. Detection of micrometeorites and solar physics get special attention.

IGY Experiments

The IGY program starts this year. This concentrated effort on a worldwide basis should solve many fundamental problems. The U.S. will fire about 200 rockets, many carrying multiple experiments.

Definitely planned United States IGY experiments include:

Number of rockets to be fired	Experiments
60	Pressure, temperature, and density measurements of the atmosphere.
19	Radio propagation experiments.
115	Aurora measurements in Arctic and Antarctic.
10	Distribution of ozone determinations.
95	Earth's magnetic field measurements at high altitudes.
57	Cosmic ray studies.

TABLE NO. 13
NAVY AEROBEE-HI ROCKET FIRINGS

DATE	MODEL NO.	REMARKS
1954	RTV-N-10B	Successful test rocket. 98 miles altitude.
1955 (2 flights)	XRV-N-13	Hot gas pressurization. Improved thrust chamber. More propellants, carried in lighter tanks. Flights unsuccessful.
1956 (3 flights)	RV-N-13-A	Improved and lighter thrust chamber, more propellants, and other improvements. One lost, another reached 117 miles and the third, only 43 miles after thrust chamber failure.
1956 (1 rocket)	RV-N-13B	This used a standard 4,000 pound thrust Aerobee combustion chamber instead of the Aerobee-Hi combustion chamber. Flight NRL-50 reached a peak of 164 miles with a 145 pound payload (an altitude record).

Foreign Research Missiles: Few But Good

Like the United States, many other nations are closely concerned with research in the upper atmosphere. Among the foreign nations to participate in rocket experiments during IGY are: France, Britain, Germany, and Japan, with possibly a small contribution from Australia. Russia's status is not yet clear. It may be that she will carry out her own rocket program independently.

French Rocket Research

The postwar missile efforts of France through the Laboratoire de Recherches Ballistiques Et Aerodynamiques in Vernon have been varied and successful. Of the many fine missiles developed the most notable is the *Veronique*. This missile was developed under the Direction des Etudes et Fabrications d'Armement which is part of the Ministry of National Defense.

VERONIQUE Missile (Model NA)

Cognizant agency . . . Ministry of National Defense.
Length, feet 24
Diameter, feet 1.8
Velocity, mph 3,200
Firing time, seconds 45
Acceleration, g. 8.2
Altitude, maximum, miles 84
Payload, pounds 133
Weight, propellants, pounds 2,160
Weight, loaded, pounds 3,180
Propellants . . . White fuming nitric acid and deisel oil.
Alternate propellant .....Turpentine
Igniting system . . . Hypergolic igniter consisting of furfuryl, alcohol.
Stabilization . . . 4 delta shaped fins
Tank construction .....Steel plate
Telemetering system . . . Transmits 20 measurements proceeding from potentionometric pick-ups.
Carrier frequency, megacycles . . . 152
Spacing of impulses . . . The information signals offer the aspect of uniformly spaced impulses (intervals are 950 seconds, duration 100-750 seconds with a 4 microsecond interruption).
Ground reception . . . The time modulation is converted to an amplitude modulation by 2 different methods.
Improvements being made . . . These include a superior metal for the manufacture of the propellant tanks. Future performance should improve.

ATEF Missile

The Comité d'Action Scientifique de Défense Nationale of France has the following solid propellant ATEF under development.

Configuration . . . Three-stage (small)
Altitude, maximum .....50 miles
Status . . . In development (it is expected that the 50 mile altitude will increase as the model improves).

Japanese Research Rocketry

The Japanese contributions to research rocketry have been thoroughly covered in an article "Japanese Rocket Research," in the October 1956 issue of this journal. *Kappa*-128-J rockets have been fired from Akita Beach during the past year. Other rockets include a *Rockoon* system, the *Baby* series and the Pencil program.

German Rocket Research

It has been reported that the German Association of Rocket Engineers (AFRA) will fire research rockets from a Cuxhaven test base to altitudes of 12 miles during the IGY.

British Rocket Research

The British, who have so far given out very little information on their guided missile programs, have finally released details of their rocket contribution to the IGY program.

Their *Skylark* has been developed under the auspices of the Gassiot Committee, and the Royal Aircraft Establishment. The instrumentation is being devised and experiments conducted by several British universities.

Proving trials were scheduled to start at the end of 1956. If initial trials are sucessful it will be extended into the middle of 1957. First flights are expected at Woomera this spring.
Research programmers . . . Royal Aircraft Establishment & U.K. universities
Cognizant agency . . . Supply Ministry
Length, feet 25
Diameter, inches 17½
Payload, pounds 65
Altitude, miles .....76 (booster 132)
Burning time, seconds 30
Thrust, pounds 11,500
Propellant . . . Solid (Raven motor)
Stabilization .....3 fixed fins
Skylark nose cone, inches 65
Launching . . . . . From an 80 foot trainable launching tower.
Guidance .....Unguided
Instrumentation . . . Telemetry—Doppler & *Deacon* tracking equipment.
Experiments . . . Possible experiments to be made with these vehicles.

1. Temperature and wind studies at 30 to 100 kilometers using grenades.
2. Winds at altitude from 20 to 70 kilometers by radar tracking of chaff released from the rocket.
3. Sodium vapor experiments, using the sodium emission to be studied by an interferometric method.
4. Day and night airflow experiments.
5. Ion mass spectrometer studies.
6. Electron and ion concentration.
7. Electron densities using radio propagation techniques.
8. Pressure and temperature.

British-Australian ROCKOON

Another program under way in both Britain and Australia is that of balloon launched rockets. These launchings will be similar to the U.S. *Rockoon* project, and will be made during IGY. Balloon launch altitudes of 13 miles have been mentioned. Initial experimental firings will be made about the middle of this year by engineers of the Weapons Research Establishment, Woomera, South Australia. Reports indicate that the vehicle to be used in this balloon/rocket combination is 18 feet long and 10 inches in diameter. Peak altitude predicted is 60 miles. ★

IONS & PHOTONS

Speculating ahead to the days of intergalactic space travel, the popular press in recent weeks has blasted off on flights of fancy about the hardware "now being built" to enable man soon to traverse the void at the unrelativistic speed of 669,600,000,000 miles per hour—i. e., the speed of light.

Aside from shaking at least one learned ion and photon researcher's confidence in the language and the press, these stories have served to compound the misconceptions that prevail among the public.

However, Convair-Astronautics Space Flight Symposium last month should have served to sharpen perspective at least a little bit. In brief, the state of the art of ion and photon propulsion research can be stated thus: theories and paper work bounded by "if's" and "when's." Assuming sources of electric power and ions of compatible weights—yet to be realized—the technology of a nuclear-powered ion rocket is known in principle. In the case of the photonic rocket, the technology is not even known in principle. Work is all theoretical.

For Those Who Don't Know

The basic theories of both systems of propulsion is pretty simple. In the case of the photon, modern theory tends to discredit the simple mechanical wave theory of light, or at least to sharply modify it. The suggestion is that rather than light mechanically distorting a "jelly-like" ether into spherical waves, light is made up of elementary quanta—small indivisible bits—of light energy known as photons. But as mass has energy, so does energy have mass, and the mass of different photons, theory goes, can be considered as varying—with the mass of an infra-red photon, for example, being half that of ultra-violet. Or, looking at it another way, ultra-violet photons have twice the energy of infra-red photons.

An ion, in general terms, is an atomic or molecular system that is mechanically balanced but electrically unbalanced. The metal sodium, for example, has one planetary electron in its outside ring. Mechanically, it "wants" to get rid of this "extra" electron so that the then-outside ring (the one remaining) will have eight. Similarly, a non-metal like chlorine has seven planetary electrons in its outside ring; also wants eight. Transfer sodium's extra electron, and the mechanical wishes of both elements are fulfilled. But they are electrically unbalanced, sodium being positive and chlorine being negative. So they stay together as sodium chloride—common salt.

However, separate them, as when they go into solution or upon the application of energy and the resultant electrically unbalanced particles are ions, both negative and positive. Being charged, they can be accelerated to very high velocities by electrical and magnetic fields. Accelerating suitable ions in this fashion is the basis of the ion rocket. It is something that is already done in the laboratory and with particle accelerators like bevatrons, cyclotrons, etc. The problem in adapting this principle to propulsion is the weight of equipment for producing power and handling all the functions that have to be handled.

The principle of photon propulsion is $E=mc^2$, where E is the energy produced; m, the mass; and c, the speed of light. It is Einstein's basic mass-energy relationship.

Dr. Ernst Stuhlinger of Redstone figures ion propulsion units could be designed to produce exhaust velocities of 100,000 meters per second and with an acceleration of 0.0001 gravities. Obviously such a system would be useful only after escape from nearby gravity fields had been accomplished.

Photon propulsion, however, contemplates conversion of mass with 100 per cent efficiency. Exhaust velocities of 300,000,000 meters per second would be achieved and produce an acceleration of one-to-two gravities. Unfortunately, nobody has a conclusive idea at the moment of how to accomplish mass-to-light conversion.

Comparison of different space propulsion systems.

Propulsion System	*Exhaust Velocity m/sec*	*Acceler. g*	*Power/-Thrust kw/kg*	*Technical Feasibility*
Chemical	3,000	1 to 8	15	Technology proven
Nuclear or Solar Power plus light gas	4,000 to 6,000	.01	20 to 30	Technology known in principle
Nuclear power plus ions	100,000	.0001	500	Technology known in principle
Phototonic	300,000,000	1 to 2	3×10^6	Technology unknown

Space, times and distances of space flight showing differences between ship time and earth time as affected by Einstein's time lengthening principle.

T r i p	*Mass Ratio*	*Ship Time*	*Earth Time*	*Distance*
Half around earth	1.00007	47 min.	47 min.	2×10^4 km

Plastic Balloons in the Rocket Age

. . . the giant offspring of the refrigerator bag helps speed space flight

By Otto C. Winzen

AS M/R GOES TO PRESS, three *Rockoon* flights are being made off Guam. Tests are being conducted at the Atomic Energy Commission's Nevada test site 70 miles northwest of Las Vegas to determine the feasibility of using plastic balloons to carry aloft a nuclear device for detonation experiments. The Navy's Projects *Skyhook*, *Rockoon*, *Strato-Lab*, and the Air Force's Project *Moby Dick* and its animal cosmic ray flights have contributed much to upper air research.

These operations point up the significant role plastic balloons are playing in space study. The October issue of m/r contained an interesting article by Kurt R. Stehling and Richard Foster discussing how a four million cubic foot plastic balloon could be used to carry to 70,000 feet a solid-propellant three-stage rocket capable of carrying a four-pound payload to the moon.

Stehling, as early as mid-1955, suggested a balloon launching method for small orbital satellites. A 3,000,000 cubic foot plastic balloon would be used to carry the proposed three-stage vehicle weighing 13,500 pounds to 75,000 feet for launching.

Small solid-propellant rockets have been successfully launched from balloons for some time. The idea for balloon launched rockets, using a cluster of balloons, was first shown in a 1947 report to the Navy by the author.

The first balloon-rocket combination was developed by Dr. James A. Van Allen of the University of Iowa's Department of Physics for the Office of Naval Research in 1952, as an inexpensive means of conducting cosmic ray research at altitudes beyond the range of the *Skyhook* balloon itself.

At about the same time the first Aerobee was being developed, the author and his associates had successfully flown the first plastic *Skyhook* balloon (OCW patent 2,526,719) on September 25, 1947. It reached an altitude of 100,000 feet and precipitated the Office of Naval Research Project *Skyhook* program designed to study cosmic rays, temperature and density of the atmosphere, and other high-altitude data.

Van Allen realized that it would be some time before upper-atmosphere research firings of large, expensive rockets could be conducted on the comprehensive world-wide basis necessary for obtaining a wide variety of scientific data. As a consequence, he devised the inexpensive *Rockoon* system with which it has been possible to explore altitudes up to 65 miles with balloon and rocket costing altogether about $1,500.

The current *Rockoon* flights are a preliminary to upper air research to be conducted during the International Geophysical Year. Such launchings are made aboard ship away from inhabited land areas and established air and shipping lanes. *Rockoon* launchings have been made by WRI and General Mills, Inc. for the Office of Naval Research from waters off San Diego, Greenland and Guam.

The 12-foot *Deacon* weighing 184 pounds is one of the rockets which is sent aloft suspended from a 72.3 foot diameter plastic balloon of 150,000 cubic foot volume. The balloon carries the rocket to an altitude of approximately 80,000 feet, where it continues to float until the decision to fire is reached. During the experiments last summer, the USS Colonial served as the launching vessel, the destroyer USS Perkins tracking the balloon with radar. When a decision to fire has been made, the rocket igniter is fired by radio control from the ship.

Used in the *Rockoon* expedition was the 72.3-foot diameter Winzen balloon made of .0015" gage polyethylene plastic film with integrally heat-sealed load bands. There were no balloon failures in 27 launchings of this type. All balloons had reefing sleeves, and weighed an average of 115 pounds.

Suspended from the balloon by a 100-foot nylon line is the *Deacon* rocket. The line terminates in a steel ring on which is hooked the rocket motor. The hook is placed so that the rocket axis is inclined at an angle of 7.5 degrees from the vertical. At the moment the rocket is actuated, the hook slips out of the ring and the rocket shatters the balloon. In the next 90 to 120 seconds, the rocket attains an altitude of 60 to 70 miles above the earth's surface. In its trajectory it telemeters data on the strength of radiations to the observing station aboard ship. The rocket-balloon combination was usually launched during the morning while the ship moved in the direction and at the speed of the wind. It was committed to firing within approximately eight hours of flight time.

The load line of a typical *Rockoon* flight consists of the following instrumentation. First, a safety control instrument designed to release the load in case of balloon failure and/or after a predetermined length of time has elapsed, to insure that the rocket will be jettisoned before drifting out of the control area. Next, there is a radiosonde (400 MC) or a WRI beacon which telemeters continuous altitude data and serves as a DF tracking beacon. Next there is often a series of radar corner reflectors. Finally, there is the rocket with its firing box which allows for a 30-second time delay to permit the electronic rocket instrumentation to reach operating temperature. The *Deacon* rocket is normally covered with a loose plastic envelope to prevent convective cooling during the ascent through the extremely cold tropopause without reducing heating by solar radiation.

When fired from the White Sands Proving Grounds, the *Deacon's* maximum altitude did not exceed 100,000 feet, due primarily to aerodynamic drag in the lower atmosphere. A tremendous boost in altitude is achieved by launching the same rocket using a balloon as the launching platform.

Payloads in the nose cone of the *Deacon* range from 20 to 60 pounds depending upon the maximum altitude desired. If electrical potentials over several hundred volts are to be used, a sealed nose is necessary so that sea-level pressure can be maintained in order to reduce the risk of corona or arc-over at high altitudes.

Following a series of three test flights of fully-instrumented rockets launched at White Sands Proving Ground in June and July 1952, the first real test of the *Rockoon* system was made off Greenland above the Arctic Circle in August 1952 for the purpose of cosmic ray investigation.

Seven successful flights were made during the initial tests, one of which was launched at 57,000 feet and reached an estimated altitude of 295,-000 feet. No significant deviation of the trajectory from the vertical occurred. Since then, rockets have been launched from balloons as high as 90,-000 feet, carrying payloads of 30 pounds into the D-region of the ionosphere and well into the E-region for a vehicle cost of less than $2,000.

Additional cosmic ray flights were conducted off Greenland in 1953, 1954 and 1955. This area was chosen because it is near the geomagnetic pole which competes with the geomagnetic equator (off Guam) as areas of special interest to cosmic ray scientists.

Even higher altitudes may be reached using the *Rockoon* system for launching inexpensive two-stage solid-propellant rockets. The October 1956 issue of m/r disclosed first details of successful flight tests using a combination of a *Nike* missile booster and an Allegany Ballistics Laboratory *Deacon* sustainer as a two-stage rocket called *Dan* for meteorological sounding at extreme altitudes.

Two test firings of the *Dan* rockets indicated that when launched from the ground, altitudes between 385,000 and 487,000 feet may be reached with payloads ranging from 10 to 60 pounds. The complete weight of the *Nike* booster was 1,324 pounds and the *Deacon* 216 pounds, giving a total weight of 1,540 pounds. Plastic balloons are currently available for carrying a *Dan* rocket to an altitude of 70,000 to 90,-000 feet. This would mean that the *Dan* could be fired above 97 per cent of the earth's atmosphere and would reach substantially higher altitudes than when launched from the ground.

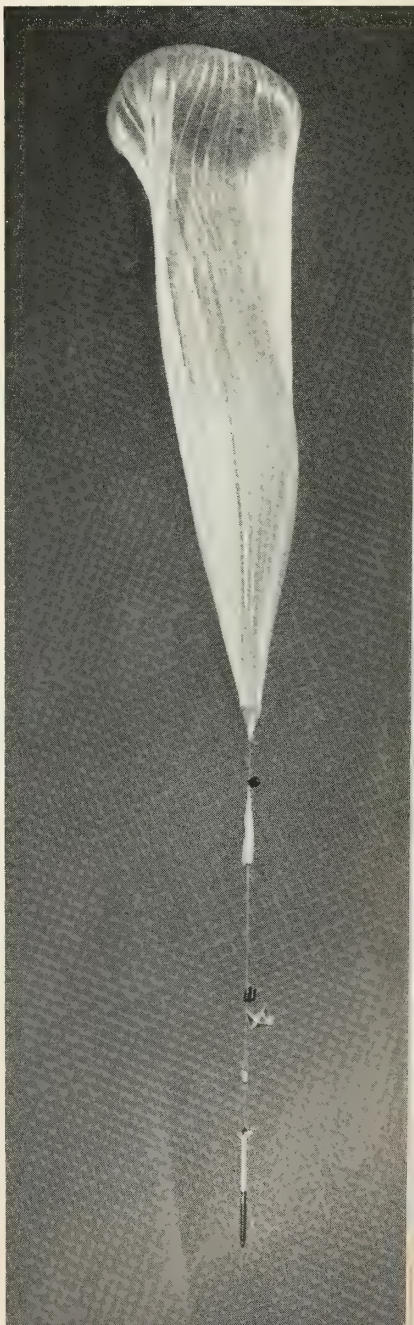
In July 1955 Kurt R. Stehling suggested a method for balloon-launching an earth satellite rocket. Even more recently, he has proposed using a giant plastic balloon to carry to 70,000 feet a solid-propellant step-rocket capable of carrying a four-pound payload to the earth's satellite.

Recent progress in the development of heavy-duty plastic balloons cause projects of this type to take on new meaning. It now appears feasible to carry aloft the orbital rocket vehicle Stehling suggests with existing balloon equipment and launching methods.

The 2,000,000 cubic foot WRI balloon would be able to haul a 12,000 pound rocket to an altitude of almost 60,000 feet. The 3,000,000 cubic foot balloon, now also in production, will carry this load to approximately 67,000 feet. The proposed 5,000,000 cubic foot balloon, weighing 2,000 pounds, should reach an altitude of 75,000 feet.

Main advantage of the larger balloons lies in their increased load carrying ability. In one launching method developed for ONR by WRI for Stratolab heavy-duty plastic stratosphere balloons, the aerostat is launched from the bottom of an open pit iron mine. Other launching techniques, including shipboard launchings, are considered practical with heavy loads. More work is necessary in developing cluster balloon launching techniques for greater loads or higher altitude.

The development in 1955 of a balloon construction with integrally heat-sealed load bands enabled the construction of a balloon which would carry heavy loads without placing undue stress upon the plastic balloon film. In the original *Skyhook* plastic balloons, adhesive load tapes were used but the adhesive failed to adhere at low temperature in the stratosphere, made prolonged storage impractical, and such tapes could not be applied uniformly along the meridians. This resulted in balloon failures. The heat-sealed load bands eliminated these difficulties.



Load bands are available with glass fiber, nylon and fortisan filaments with high breaking strength. They transmit the lift from the fabric to the load along equally-spaced meridians of the balloon. The fabric then serves primarily as a barrier material for the lifting gas and secondarily as a load-carrying member, not as the main load carrying member as in the case of the former rubberized-fabric balloon.

The load-bands of the desired breaking strength are heat-sealed into the seams of the gore material. In the two million cubic foot heavy-load balloon, there are a total of 120 stressed load bands. The balloon shape is determined on the basis of minimum latitudinal stresses for a given fabric, weight and load.

While the balloons discussed here employ two mil gage polyethylene, heavier or stronger materials are available as are load bands of several times the 500-lb. test bands used in the two million cubic foot heavy-load vehicle which has a theoretical bursting strength of 20,000 pounds.

WRI, in addition to other balloon instrumentation, has developed several positioning devices to provide precise firing orientation. These are simple servo systems originally developed with ONR to orient cameras along a given azimuth and elevation for the purpose of astronomical studies from balloons. The plastic stratosphere balloon floating at ceiling altitude represents an extremely stable platform free from oscillation and of very low rotational

Rocket goes aloft by plastic balloon.

velocity. A carefully designed rocket suspension system can therefore be maintained in a known attitude without difficulty. Stability along the vertical axis is not a critical problem.

For the azimuth angle of the rocket, the servo systems developed employ an earth-inductor compass as a reference and the payload is rotated against the inertia-mass of the balloon which is of a very high order of magnitude. Two systems have been designed. One, automatic, in which a rocket could be held in an attitude of a pre-set direction and elevation automatically. Two, controllable, in which the attitude of the rocket could be changed at will from the control center on the ground by radio command.

Both systems will telemeter attitude angles to ground stations. The resolution of such systems can currently be held at least to one degree with closer control possible. The orientation devices are simple since they needn't include gyro-stabilization.

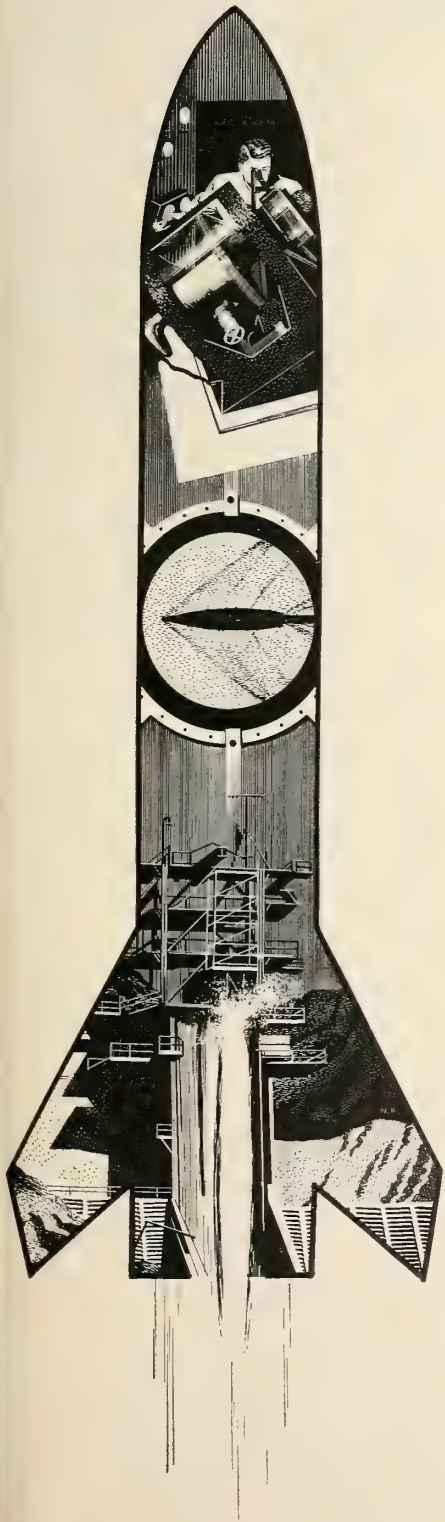
A further extension of the use of balloons in rocket research would be the use of a five million cubic foot balloon to carry aloft research gliders or rocket planes. The weight of present research rocket planes is in the vicinity of 10,000 to 16,000 pounds. The aircraft could be carried to a height as great as 80,000 feet on the five million cubic foot balloon before it is released. Ascent time would be one and a half hours. Cost would be less than the present method of taking research rocket planes aloft by a mother plane. Release altitude would be 40,000 to 50,000 feet higher, and the plane could spend a greater portion of its flight time at high altitudes.

One disadvantage of this system would be the absence of attending personnel such as are present in the mother airplane. This could be remedied by using a gondola which would contain personnel and equipment and power for monitoring the aircraft during the ascent, and assisting in the launching of the rocket aircraft. Assuming a gondola weight of about 2,000 pounds, the launching altitude would be reduced only 3,000 feet using a five million cubic foot balloon.

Round the World Balloons

A recent issue of *Newsweek* suggests that upper atmosphere researchers are considering putting their instruments aboard around-the-world balloons which would be slow-freight companions for the artificial earth satellite. One handicap to tracking the satellite from ground stations presently proposed would be the difficulty in doing so during extended periods of bad weather. A balloon gondola suspended in space with two observers could visually track the satellite by telescopes without having to worry about weather. The capability now exists to maintain such a space laboratory aloft at an altitude of 80,000 feet for a week. It would be hard to imagine a better observation platform for tracking the satellite than such a space station. When aided by the jet stream at the base of the stratosphere, circumnavigation of the earth could be accomplished in 100 hours or less. It would also give *Vanguard* scientists an opportunity to check out their airborne and ground equipment devised for the tracking of the satellite.

Rocket launching balloon at its peak altitude, as photographed through telescope.



Plastic high-altitude rocket research balloon being inflated at night.

Much of the balloon's work is done at lower levels. Its feats of endurance and long distance voyages are nothing short of remarkable as it floats for days over oceans and continents.

The balloon floating at altitudes currently up to 145,000 feet is a floating laboratory—an ideal observatory as demonstrated by the University of Minnesota—as it hangs motionless with respect to the surrounding atmosphere. In a sense it is a satellite of the earth. It is a stable platform ideal for the execution of research experiments.

So the balloon, man's oldest aerial vehicle, and the rocket, man's newest aerial vehicle, have been linked in discovering the secrets of space. ★

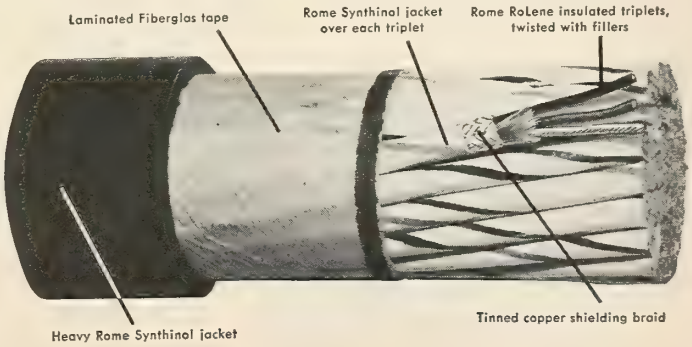
Special 111-conductor Rome cable solves tough guided missile problem

When project engineers at North American Aviation, Inc., needed a special telemetering cable for their advanced guided missile work at various missile test centers, Rome Cable Corporation was asked to make it.

The cable was a tough one to manufacture. The specifications called for exacting dielectric requirements, low-loss characteristics, adequate service life—and a total of 111 conductors—all contained by one heavy-duty jacket.

Because Rome Cable engineers are accustomed to solving tough cable problems like this, they readily produced the cable which met North American's rigid specifications. Rome RoLene—a polyethylene compound—proved perfect for insulating the 37 triplets inside the jacket, and it easily met the specification requirements calling for controlled capacitance and uniform wall thickness. Rome Synthinol, a tough polyvinyl chloride compound, proved to be an excellent jacket material.

Rome Cable can also help you



You can turn to Rome Cable with confidence for the right solution to *your* special cabling problems. Rome's competence in its field is, in part, a function of the following factors:

1. Engineering experience. Rome engineers regularly handle complicated specification problems. They've had years of experience dealing with electronic circuit problems.

2. Complete production facilities. The completeness of Rome Cable's manufacturing facilities is unique.

3. Uncompromising quality control. Latest devices, like the photoelectric gauge, are regularly used to assure highest quality. This particular gauge enabled Rome to maintain an exacting control on the diameter limits of insulations and jacket for this special cable.

Rome Cable's engineers can probably be of real help to you on your next cable problem, especially if it is a really tough one. For more information as to what we can do to help you, simply contact your nearest Rome Cable representative—or write to Department 850, Rome Cable Corporation, Rome, N. Y.

"QUALITY CONTROL"

For over a decade, Narmco structural adhesives and laminating materials have been produced under a quality control program with "teeth" in it. Quality control moves from exacting inspections of incoming materials through all the steps of compounding today's most advanced types of plastic adhesives and structural laminating products.... through mixing, material processing, final tests and shipping....and even into the user's production departments ....safeguarding the manufacturer's own quality control program!

Standards of quality are rigidly maintained at Narmco, year after year....standards the user can depend upon! And they save production and re-work man-hours....help the airframe and missile manufacturer do today's toughest job....that of meeting tight production schedules under budget. That is why Narmco's assured quality "Metlbond" adhesives and "Conolon" laminating materials are constantly being used in greater quantities and in new ways.... *doing jobs every day that metals alone can't do!*

To the manufacturer who uses Narmco products in the production of aircraft and missile parts and assemblies, Narmco's quality control means better parts....more uniform parts....at lower cost....and on schedule!

NARMCO

PIONEERING THROUGH RESEARCH

Narmco technical field representatives throughout the United States and Canada can assist in solving your structural design problems quickly, efficiently and economically. For immediate assistance, write, wire or telephone ...

NARMCO RESINS & COATINGS COMPANY, Dept. 9 600 Victoria Street, Costa Mesa, California

Astronomer Fred Whipple

. . . wants more basic research by Defense Department

. . . urges start of post-Vanguard projects now

Last month Defense Secretary Wilson abolished the office of Assistant Secretary of Defense for Research and Development and combined its functions under the newly established Assistant Secretary for Engineering and Research. This personal report *emphasizes the growing danger of de-emphasizing basic research in the Defense Department. Astronomer Dr. Fred Whipple is the country's leading upper air researcher. He knows the increasingly close relationship between basic discovery and modern weaponry. He has been a proponent of space flight for many years.*

Q. *Dr. Whipple, you are Chairman of the Upper Air Rocket Research Panel. Is that right?*

A. Yes. I wear several hats. I'm professor of astronomy at Harvard. I'm also Director of the Smithsonian Astrophysical Observatory. My interest is basic research. As you well know, that's the spring that feeds all the rest. If it dries up, we're out of luck.

Q. *Do you feel we're spending enough money on basic research?*

A. It's not so much the amount of money we're spending, but the way it's spent. Many people in basic research cannot or do not plan ahead.

Q. *Do you feel a Czar is needed to coordinate and direct basic research in this country?*

A. You do not need somebody to coordinate or organize basic research. You need enough communication so that the interested scientist knows what others are doing. And you need enough continuing long-range support so that they know what they can do. If you provide communications and continuity of funds, then you don't have to coordinate; you don't need a czar in basic research. This is a critical point, because in development you do, and when you get to hardware you certainly have to have it. But in basic research, freedom is essential.

Q. *Is communication satisfactory the way it is now?*

A. I'm not sure it is for all basic research. It is, for example, in terms of upper air parameters. There, we're dealing entirely with unclassified material. The weakness is in funding procedures. Research contract renewal too often takes place after the end of the previous year's contract. It takes a research man with a lot of persistence to get into this when the funds are so erratic.

Q. *Is this a function of the Congressional method of making appropriations?*

A. Partially, though I think Congress is very appreciative of these problems and has done very well. It is simply that there are a lot of steps in the chain. You can have high level policy; you can have Congress saying "we want basic research done"; you can have the Bureau of the Budget backing them up; you can have top-flight Defense men in each of the services backing them up. But by the time it gets down through the chain of command and the various people, the original intent is lost. Long-range programs, thus, are very difficult to set up.

Q. *Since World War II, haven't we established different organizations—Office of Science Research and Development, National Science Foundation—that are supposed to do precisely this?*

A. Yes, and given time, I think the National Science Foundation will do so. It had very limited backing at the beginning, but it's probably growing now about as fast as it can and still be effective. There is a point I want to make here. I feel more basic research should be conducted within the Defense Department. The policy of removing basic research from Defense which unfortunately still continues is, I feel, basically unsound. The military must make extremely grave decisions in guiding the future of our defense. The instrument of war a decade from now is perhaps still a spark in some scientist's head today. Now these decisions must always be made by administrators essentially in the Defense Department. If they have research scientists in their organizations who also are constantly aware of defense needs, then those men will have good judgment and can advise their administrators wisely. If, however, Defense administrators must go to outside consultants, then they are going to get good judgment in regard to science, but they are probably not going to get good judgment as to its utility as a weapons system. They must have research scientists—and I rather stress this point—must be research scientists within the Defense Department because no scientist who has given up his research and gotten into heavy administrative work can have this judgment any more. I think he loses it very rapidly when he leaves his laboratory and his pure research interests. Now good scientists who work in Defense tend to leave.

Q. *He goes into industry and becomes a project engineer which is heavily administrative. He's good, Because he's good, we lose him.*

A. Right. In Britain, it's said, if a man proves himself a good scientist, they give him three assistants and tell him to go ahead. In America, everybody pats him on the back and gives him three new jobs. I'm afraid there's a little truth to this.

Q. *In this regard, there's another advantage British scientists have, though we might consider it as a disadvantage. They lack money. They can't use the shotgun approach to a problem. They have to think it through first. They say; "There are a hundred possible ways of doing this"—They figure out the best ten and then maybe choose three of them. This is what they did in their atomic power program. It requires a lot of good, clear, careful thinking before you mount a test tube or turn a lathe, so to speak.*

A. This is relevant to the point I made a moment ago about the need for the basic research scientist in the Defense establishment. They can point out those areas that

are most likely to succeed. If we have lots of money, we can apply the shotgun technique. The difficulty is that nobody then has the courage to cut off useless, unpromising development. Basic research should be judged by its quality, not by whether it is successful or promising. Development, on the other hand, must be judged as to whether it is successful and promising and you must cut off development when you see you are going down a blind alley. In Basic research you must explore all these alleys because they may turn out not to be blind after all.

Q. *Negative results are answers as well.*

A. That's the point.

Q. *Do you feel defense has a proper appreciation for basic research?*

A. My impression has been since World War II that the group of people most appreciative of basic research in this country, outside the universities, is the military. But there are certain policy matters that get the thing tangled up.

Q. *What do you think the primary function of an organization such as the National Science Foundation should be in the case of basic research?*

A. It should determine the needs and help fund them on a long-term basis. NSF can do this if it is given further backing by Congress so that it can grow to a larger size.

Q. *Do you think it would be a good idea for the Defense Department, say once a year or so, to sponsor basic research symposiums in different fields, such as upper air research, inviting people from industry, universities and the three services to discuss problems and progress?*

A. I certainly think it would. I want to make it clear that quite a bit of my criticisms are broader than upper atmospheric research. I've talked about basic research generally, materials, solid state physics, etc. All are relevant.

Q. *Can you state briefly where knowledge begins and leaves off in upper air research?*

A. First, you must know how much air is up there. We can do very well to something like 100-to-150 miles with sounding rockets. Then the rocket technique essentially fails because the density is too low for the instruments. Also the outgassing of the rocket provides more gas density than the air. You must leave the rocket up there long enough to de-gas, which obviously you can't. Then you have the problem of ionization. This affects communication. Astronomical methods, radio astronomy, reflections from the moon will tell you the total electron content of the entire ionisphere all the way to the moon and back again. The problem of telling the distribution is difficult. Then another area in which we know nothing of these high altitudes concerns magnetic fields. In all these cases we have to turn to the satellite.

Q. *Won't magnetic measurements require a heavier satellite than the Vanguard?*

A. It's hoped that six pounds will do it.

Q. *Would the six pounds provide for continuous readings in flight or would it store the data and play back?*

A. It would probably take periodic measurements and play them back over telemetering stations.

Q. *On returning to earth, at what altitude would the satellite get so hot it ceased to function?*

A. Well, in a nearly circular orbit that is contracting, it will begin to become hot at some 40 miles.

Q. *Can you tell us something of the latest plans for launching satellites during the International Geophysical Year? Aren't we going to launch something like 10 or 12?*

A. That was the original plan, but that has been cut back to six. The optimists say we're going to get most of them up, and on the other hand the pessimists say, well, we might not get any up. I think the expectation of those closest to it is that about two out of six will be successful.

Q. *What's the criterion for success?*

A. That it goes into an orbit with a minimum perigee of 200 miles and an apogee of anywhere from 300 to 1500 miles. In an orbit of this sort, it should stay up for about a year. The program as it's planned now, includes four prime experiments. After at least one or two shots for testing, Number One will carry experiment Number One. If the satellite is successful, satellite Two carries experiment Two. But if One fails, satellite Two will carry experiment One. If that also fails, satellite Three will carry experiment Two. Each experiment gets two chances. Now, of course, that doesn't guarantee that Four gets to fly at all.

Q. *If the Army Ballistic Missile Agency were to come up with another launching vehicle, as they claim they have, is there anything in the nature of IGY to prevent the use of launching methods other than* Vanguard?

A. I would put it this way. In order to put a satellite in another vehicle, it would have to have different dimensions and would have to be integrated to that vehicle. And it's probably too late now to start any new plans for the period of the IGY.

Q. *What about follow-up satellite plans to continue on where the IGY program leaves off?*

A. Well, they should have been started by now. This illustrates the research planning problem I mentioned earlier. There are a number of people who would like to start working on experiments for satellites. It takes a long

Don't need a czar . . .

In basic research, freedom is essential.

Negative results are also answers.

time to develop those things, and the more time you have the better you do. Two years is not a long period at all.

Q. *In the IGY, you're concerned with tracking the satellite aren't you?*

A. Yes, one of our big projects is the satellite tracking camera.

Q. *How many of these are you going to make?*

A. Twelve—only two to be stationed in this country near White Sands and in Florida. Others will be in the Netherlands Antillies, Peru, Argentina, South Africa and Australia. That's seven. Five will be stationed around the earth between 35 degrees north and south latitude—Hawaii, Japan, India, Iran or Egypt and Southern Spain.

Q. *You're not sending one to Russia?*

A. No, we haven't been invited to send one. But the primary reason is that we're trying to space them in the low latitudes.

Q. *Has there been much liaison with the Soviet Union in this program? Sedov at Rome and Bardin at Barcelona made statements, for example.*

A. That's right. I saw Bardin at Barcelona. They have made no embellishments on these statements whatsoever on an official basis. They indicated they were going to cooperate, but from my knowledge, no official information has come from them concerning the obvious questions you would ask—what, when, where?

Q. *Will any of the satellite experiments be designed to contribute to the basic study of matter, subnuclear particles, for example?*

A. Nearest to it will be the studies by James Van Allen, Iowa State, of cosmic rays, high energy problems. Of course there are those who would like to plan more fundamental experiments, particularly to distinguish between two types of time as suggested by Milne many years ago—astronomical time and nuclear time—to see whether there is a fixed relationship between them as modern physics assumes. Dr. Markowitz at the Naval Observatory has a program on this, carried out with cesium clocks on the one hand and moon clocks on the other. He expects some sort of answer to this by, I believe, 1973.

Q. *Suppose the relationship does vary. Where does that leave us?*

A. Just one step further along the way—one step further into mystery. This is the way science progresses.

Q. *What about Einstein. Will the satellite be used to confirm time lengthening or other Relativity postulates?*

A. Probably not in the IGY satellites, though nearly everyone interested in the field seems to think it might be possible. You have to be able to put an atomic clock in a satellite. Those now in use weigh hundreds of pounds. I've talked to Professor Zacharias at Cambridge about this and he thinks he might get one down on the order of 50-to-60 pounds, including power supply.

Q. *If the satellite stays up a year, would it be possible to confirm the perigee advance?*

A. I think not, because of the amount of interplanetary material as well as what we might call high atmospheric material. This would have too much of an effect on the satellite's orbit for the very small perigee advance to be measured. In order to overcome this uncontrollable margin of error, your satellite would have to be on a pretty grand scale.

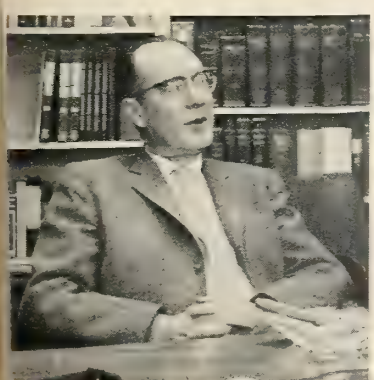
Q. *What is the outlook for making visual observations by satellite?*

A. Well, I do not take very seriously these manned satellites as being the proper answer. The next step is a large enough satellite and a small enough power supply, nuclear or solar, that they can be brought together with very moderate weights—100 pounds or so. Then you can put in television. This opens a whole new area of research that cannot be done by the IGY satellite.

Q. *How about a telescope in the satellite?*

A. Well, a 40-inch reflecting Schmidt, though with a somewhat longer focal length than the Palomar Schmidt, would give you all the resolving power of a 200-inch telescope under the atmosphere. Also, you could do tricks with pairs of interferometers. An interferometer on earth is limited to something like 20 feet before the atmospheric scene knocks it out.

Q. *Are there plans for capturing and identifying such things as subnuclear particles?*

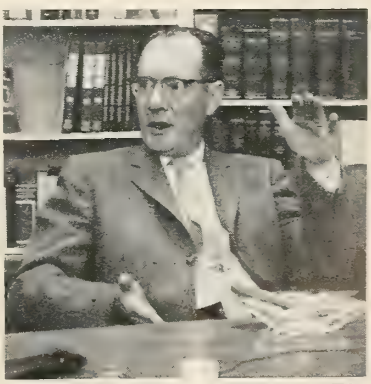


A. Yes, possibly from the sun. I'm extremely interested in micro-meteorites, the fine dust in space. We know very little about this dust in outer space.

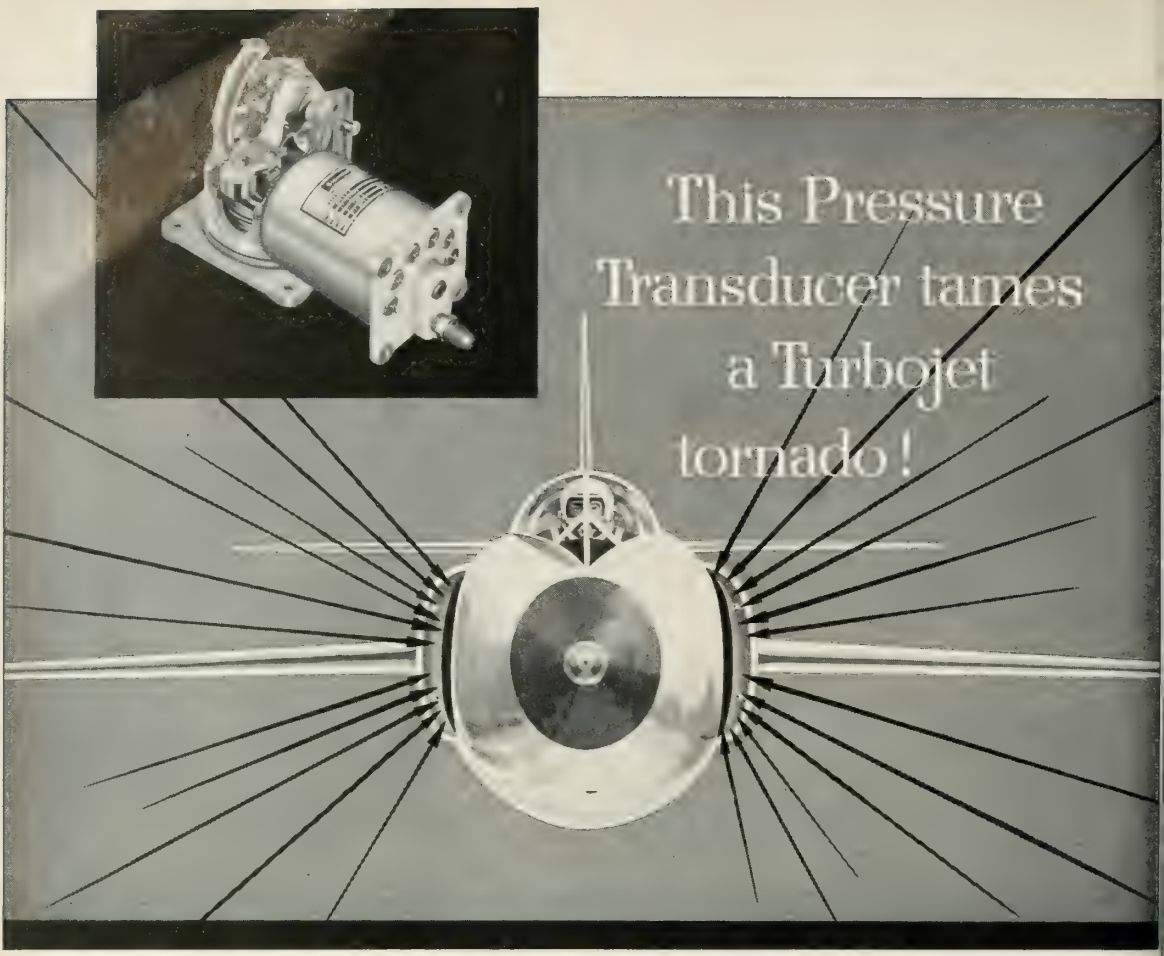
Q. *How are you going to study these?*

A. Well, some have been brought back on rockets with plastic surfaces.

Q. *Will you have devices on one of the IGY satellites to tell if a particle hits?*



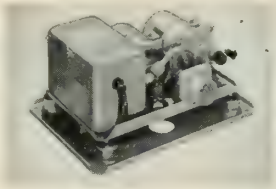
A. Yes, in the first satellite experiment (Naval Research Laboratory) there will be pressurized sections which larger dust particles would puncture. We can record this with telemetering equipment. We will also measure sound. Through a combination of all these I think we will get some answers. ★



We have to turn to the satellite.

A larger satellite . . . smaller power supply.

For 100 pounds . . . you can put in TV.



Controlling the tornado of intake air consumed by supersonic jets is the latest assignment of Giannini's High Resolution Pressure Transducer. This versatile instrument plays a key role in maintaining optimum efficiency of today's newest and most advanced high performance turbojet engines.

Two of these transducers form the heart of the Giannini designed and produced Variable Inlet Control System which limits diffuser air to a steady subsonic flow at all speeds and altitudes. Static and total air pressures in the diffuser throat are sensed by absolute and differential versions of the transducer, and this data is transmitted to a computing element. The ratio of pressures is compared to a stable reference, and error signals are fed back to position a variable obstruction, or ramp, in the inlet duct.

By using these unique pressure instruments as sensing elements in the Giannini system, several distinct advantages result: the transducers can be located near the pressure probes, minimizing pneumatic tubing length; no stable amplifier is required since the high level output of the transducer potentiometer pickoffs can be used directly; no repeater servo is required; the system is flexible, control pressure ratio being altered merely by adjusting the reference; the computer can be located remote from the transducers.

The Giannini Variable Inlet Control System is typical of applications to which this instrument can be put. **Capabilities** of 350 volt output, 2000 wire resolution, 0.8% linearity, repeatability to 1% of *reading*, and its rugged insensibility to vibration and shock make it ideal for use in the most critical airborne controls and systems... In case you're not interested in taming a tornado—perhaps it's only a mild breeze—Giannini High Resolution Pressure Transducers are admirably suited for telemetering and control applications requiring the ultimate in accuracy and sensitivity.

TERRAPIN ---

the do-it-yourself rocket

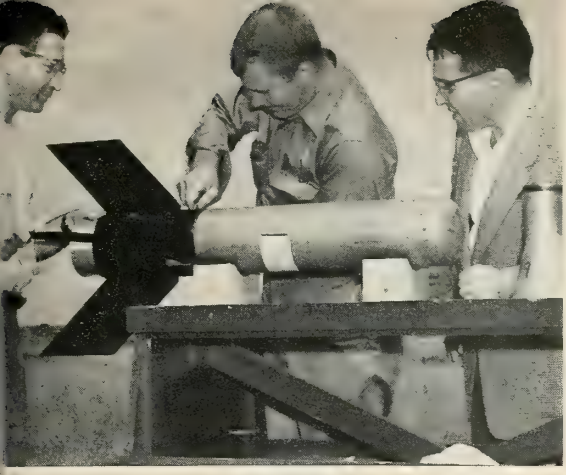
TERRAPIN instrumentation payload including radio transmitting antenna and nose cone. Its nose cone section can be varied in length to accommodate equipment weighing from four to 24 pounds.

The reason for it all—payload containing power supply, telemetering equipment, accelerometer, spin detector, and other test gear is fitted in place. TERRAPIN breaks down for easy transport.

By Professor S. F. Singer

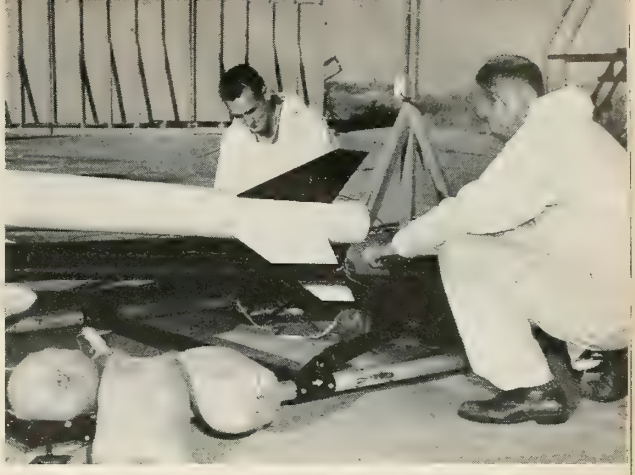
Physics Department
University of Maryland

THE BASIC FUNCTION of a University is teaching, and the justification for research at a university is that it is the best method for teaching advanced work. At the present time, when there is a great demand for trained scientists in the field of rocket technology, telemetering techniques, upper atmosphere physics to name just a few, there is a woeful lack of facilities for training such personnel.



It is of greatest importance from a national point of view, as Captain Grayson Merrill has pointed out, to establish such training for qualified young engineers and physicists at academic institutions of higher learning.

One of the best means of carrying on a graduate teaching program in these fields is through the medium of high-altitude research with small rockets. This work embodies all of the technological phases, such as rocket propulsion, aerodynamics, telemetering techniquies, electronic instrumentation and in addition, it provides an opportunity for research in upper atmosphere physics, cosmic rays and other extra-terrestrial radiations. These fields of research have basic significance for geophysics, astrophysics, and in general, give us a better understanding of the environment of the earth. This research will gain considerably in practical importance as means are developed for projecting vehicles into the space around the earth.



2.75-in. FFAR costs $50

A number of universities are now involved in high altitude rocket research: Colorado, Iowa, Michigan, Utah, to name just a few. Here at the University of Maryland we are doing high altitude research by concentrating on the small research rocket, with emphasis on the word "small." We started out by undertaking the development of an aircraft launched sounding rocket, the little 2.75 inch FFAR which weighs only about 15 pounds and costs $50.

Our first task was to squeeze into its tiny warhead, a few cubic inches: a cosmic ray counter, high voltage supply, premodulator circuits, 403 mc transmitter, and of course batteries to drive the instrumentation. Through co

Attaching TERRAPIN'S second-stage rocket engine assembly to second-stage fin section. Left to right: Republic Guided Missiles Div. Project Engineer MORRIS ROTH, NACA's GEORGE CUTTER, and SIDNEY HELFMAN, Republic's Aerodynamics Div. Chief.

Attaching firing box before raising TERRAPIN on its zero-length launcher are ROY HINDLE and EDWARD MATHEWS of NACA. First firings of the TERRAPIN were conducted jointly by representatives of Republic Aviation, NACA and Maryland University.

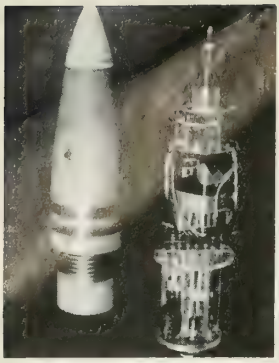
operation with the Office of Naval Research we arranged for 5 test firings and although reasonably successful, it soon became apparent that dependence on an aircraft is not very satisfactory for a university operation. We needed a do-it-yourself, or rather launch-it-yourself vehicle.

We therefore concentrated next on a two-stage ground-launched rocket following a general scheme pioneered by the NACA, but again on a much smaller scale. In collaboration with Republic Aviation we designed the *Terrapin* high altitude sounding rocket, a 200 pound midget, consisting of a modified ABL *Deacon* first stage and a *Thiokol* T-55 second stage. This rocket with some slight modifications is capable of carrying 25 pounds some 80 miles into the ionosphere and is becoming our work-horse for upper atmosphere experiments.

Initial instrumentation on the *Terrapin* was concerned as much with sending back readings on the rocket itself as it was with sending back readings on the upper atmosphere. This was necessary to check the performance of the vehicle itself, since being a new configuration, it had never been fired before.

Ease of Handling, Launching

The great advantage of the small rocket is its ease of handling and launching. In the case of the ground-launched rocket vehicle, where the dispersion is low and range safety requirements can easily be satisfied, it becomes possible to conduct firings from the continental U. S. We have made several firings now from the eastern shore of Maryland, only a couple hours drive from our laboratory. We look forward to the day when 2 or 3 of us can simply leave in the morning with half a dozen instrumented rocket heads in our little stationwagon (which also serves as the telemetering receiving station), arrive on the proving ground, set up the launcher in a matter of a few minutes, put up the rockets and fire one instrumented head after another, collect our data, and drive home again after a good day's work. Things are almost at that stage now, and with further experience, rocket experiments may become so simple that they will not interfere with the other duties of a university graduate student.



We are now in the beginning stages of a small-rocket upper atmosphere program, which will investigate many important high altitude phenomena; cosmic rays, solar radiation, micrometers, the earth's magnetic field, the day airglow and night airglow, the aurora, magnetic storms and others.

From this work master's and Ph.D. theses are beginning to flow. Typical publications by students include: "The design of an FM/AM transistorized telemetering system"; "The design of heat sinks for rocket telemetering instrumentation"; "Radiation equilibrium and temperatures of earth satellites."

Upper air research at a university often leads to basic progress in sounding rocket technology. For example, we have looked into a method of theoretically optimizing the design of a two-

It takes only three men to raise the completely assembled TERRAPIN into firing position. Pins in the launcher platform can be set into the earth to supplement the sand bags in holding the launcher firm. Pictures were taken during first TERRAPIN tests.

2.75-in. FFAR research payload. It takes some real doing to cram so much gear in so little space.

Though TERRAPIN was designed specifically as a research rocket, and FFAR is converted weapon, the latter is still a good research tool for Universities. And it costs only $50. Its disadvantage, however, is that it must be aerially launched.

stage rocket in the presence of atmospheric drag. This theoretical work has paid off in terms of a new design to project a five pound payload to over 1,000,000 feet, the vehicle as a whole weighing only 75 pounds.

When this vehicle is finally built we hope that it will be a truly low-cost University research rocket, one that will be simple and flexible enough to fit in comfortably with our unelaborate transportation and launching facilities. It must be kept in mind universities cannot justify the time and expense of setting up and maintaining a full scale test-missile launching base.

The simpler rocket scheme, however, makes the instrumentation job more difficult in terms of weight and space, but this emphasis has its advantages. It forces our students to consider the important aspects of an experiment and the telemetering instrumentation, and it forces us to compress the essential circuitry into the minimum space with the minimum weight.

We are approaching the day when the small rocket will be a commonplace research tool, as commonplace and (perhaps) even more useful than the rubber balloon which has been used in previous years to investigate the stratosphere. For the leaders of this research we must look to the men who are now receiving their training in this field as university students. ★

TERRAPIN in its launcher and ready to go. A major design objective was to cut preflight assembly and preparation time to a minimum.

TERRAPIN, named for the slow-moving turtle, streaks skyward at 3,800 mph and telemeters back research data during its 80-mile trip.

LOCKHEED F-104

LOCKHEED F-104 and the CHANCE VOUGHT F 8 U use 16 PERMANENT FILTER SINTERED BRONZE units to protect hydraulic and pneumatic components for top, supersonic performance . . .

When perfection is demanded...
the answer is PERMANENT FILTER installations!

Faultless operation of servo-mechanisms in aircraft—and in rockets and missiles—is an absolute essential. Filtration must be completely efficient regardless of altitudes, temperatures, or pressures. That is why PERMANENT FILTER installations are standard in hydraulic and fuel systems of leading military aircraft and our latest missiles. PERMANENT FILTER units not only meet these demands but provide economy in installation and dependability of operation.

Whatever your filtration problems, PERMANENT FILTER "engineered ahead" units are ready to solve them. In addition to operational filtration elements for hydraulic oils, for fuels, gases, liquid nitrogen or liquid oxygen, units are also provided for the bulk filtration of most liquids and gases.

PERMANENT FILTER Sintered Bronze filter elements are available in 400 standard types to meet 2-micron to 40-micron specifications. These units are designed to withstand 100 G shock at temperatures from −350°F. to +750°F.

NEW! In answer to Industry's demands, a new and revolutionary means of oil purification will soon be available to manufacturers of high priority defense equipment.

Qualified Representatives are invited to write regarding remaining sales territories yet open.

Write or wire today to Dept. M-R-3-7 for new 1957 catalog.

Each pound of reduced weight is worth something to you. The new Bendix Pygmies reduce connector weight drastically. These miniature aluminum connectors are for compact electronic equipment and aircraft use. Contacts are size 20 heavily gold-plated, featuring machined closed entry sockets. Choice of quick disconnect coupling between a modified double stub thread or 3 point bayonet lock. Provisions for grommet sealing, potting, cable sealing, conduit applications.

Bendix "Pygmy" Connectors weigh less, take up less space than Standard AN Connectors. Think of the advantages!

Available in a wide variety of shell styles and insert arrangements. Shell sizes range from $\frac{3}{8}$" I.D. to $1\frac{3}{8}$" I.D. and incorporate from 1 to 55 contacts. Write Dept. PC for descriptive literature on this dramatic improvement in Aviation Electronics.

Scientific Methods Replace "Fire-Fighting" Approach

By Henry P. Steier

MISSILE MANAGEMENT from design to combat use may some day be as scientific as mathematics.

Based on a numerical evaluation of certain missile program factors it is predicted this new science could do much to improve missile weapons system effectiveness.

These factors, according to E. H. Bender, Office of the Assistant Secretary of Defense (Engineering), Guided Missile Directorate, are: producibility, operability, reliability, maintainability, and performance capability.

In a talk before the recent National Symposium on Reliability and Quality Control in Electronics, Bender said best missile program management requires a trade-off of the relative values of these "abilities" during design, development, production and field test.

The derivation of measurement techniques for assigning numerical values to the abilities appears to be within reach but requires much improvement and refinement, Bender declared.

When they are available in the future, worthwhile savings in time, material, manpower and money are expected. End result would be earlier delivery of more effective guided missile systems to the armed forces.

The "fire fighting" approach used today to complete a missile system causes pronounced overlaps between program phases. Overlap occurs when design, development and prototype construction, etc. are done concurrently.

It is the aim of studies underway at OASD to remove the overlap and thus save time through the development of a more scientific approach by optimization of the controllable abilities.

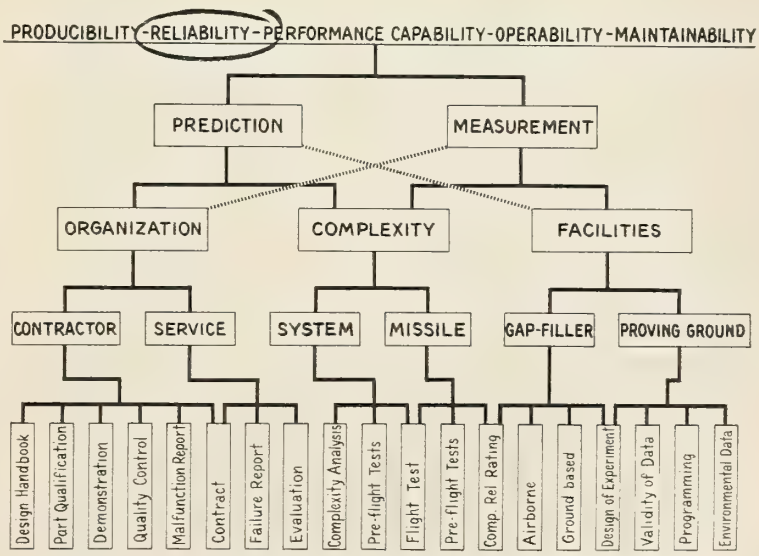
Thus far work by OASD has shown reliability to be the area which would yield the greatest improvement in weapon system effectiveness. This is because of the existing low reliability level and high cost per missile.

For its purpose, OASD defined reliability as the inherent ability of electrical, electronic, and mechanical equipment is a weapon system to produce the planned operational effect while operated by military personnel.

When it undertook its missile management improvement program OASD set these goals for its work in the reliability area:

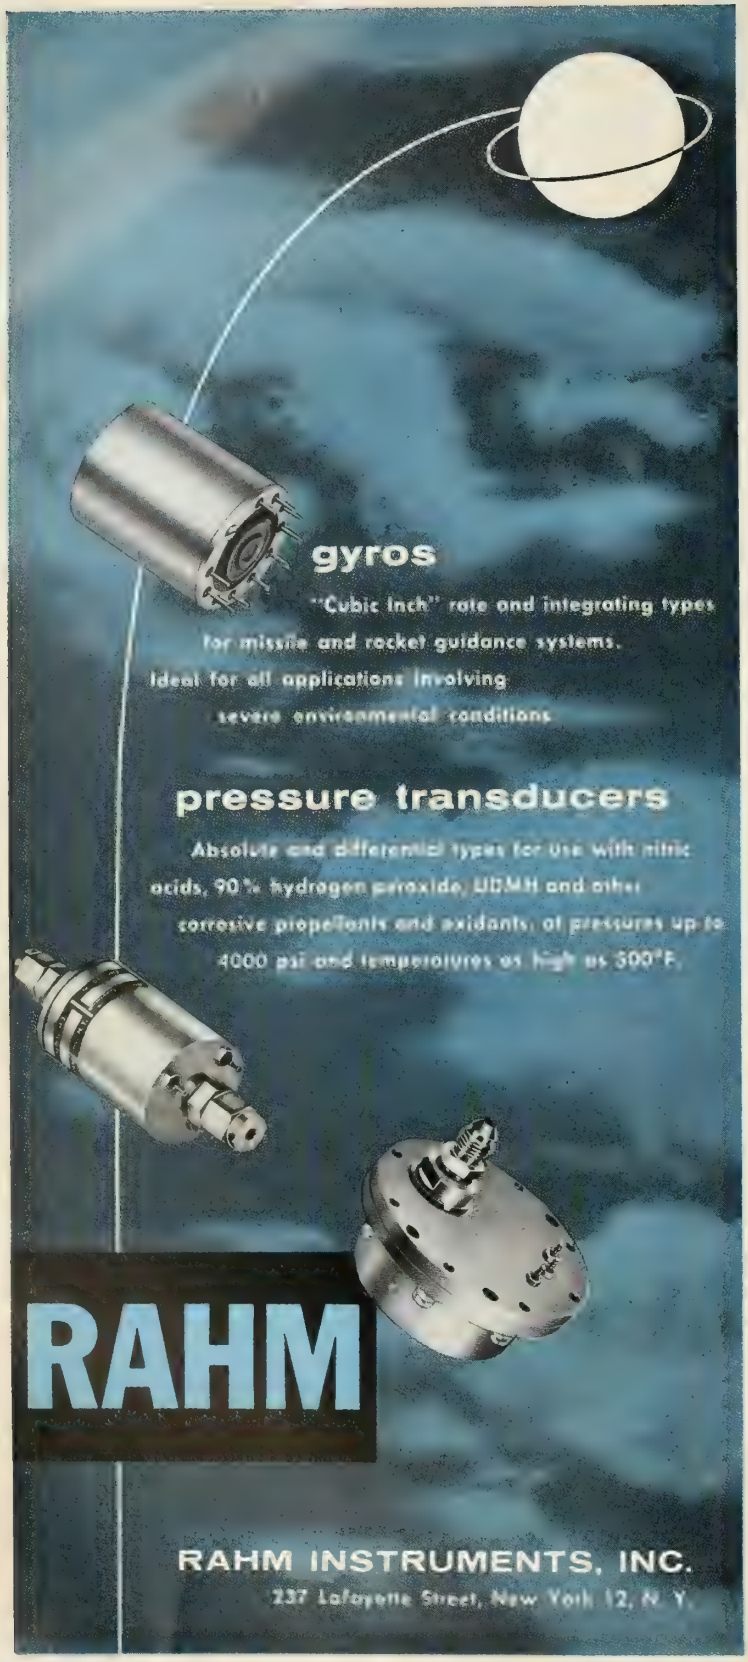
- Reduction in development time without telescoping of phases, or crash programs.
- Improved reliability level with reduction of workload on facilities and manpower.
- Reduced weapons system and evaluation costs.

Ground rules for the approach to these goals were based on five "convictions." The convictions established the questions and problem areas to which various groups of an adhoc committee were to direct their studies.



First, OASD believed reliability could be improved. Some people are pessimistic to the extent that they hold unreliability is a necessary evil. OASD reached its conclusion based on maturation of new techniques and observation of progress in other areas.

It is believed reliability should be a design parameter and should be specified and designed into equipment just as performance parameters are.



Accurate methods of predicting equipment reliability are needed and can be obtained. When they are, realistic procurement specifications can be written, and realistic weapons use planned. The basis for this prediction would be relationship between design, operating environment and reliability.

The committee felt shortened test cycles and improved validity and accuracy of information would accrue from scientific experimental design techniques. This would come mainly from use of simulators, high speed test tracks, flying test platforms, and restrained firings. These "gap fillers" would reduce missile test flight limitations imposed by cost and proving ground time available.

Lastly, the committee was convinced that present equipment specifications do not insure a satisfactory level of reliability over the intended service life of the missile system. Although accuracy and lethality are specified in almost all missile system contracts, these parameters are often demonstrated and then accepted on the basis of limited data based on impact or distance of burst from the targets.

Earlier delivery of more effective guided missile systems is expected if the "abilities" shown could be handled on a numerical measurement basis. Shown are relationships of factors under study by Defense Department to aid in developing reliability as such a management science.

Other system parameters may have been varied from realistic tactical conditions.

To establish recognition of individual problems among the different abilities under study, objectives were delineated and a problem structure organized as shown on preceding page.

Beginning with "prediction" and "measurement" in the case of reliability, OASD's initial effort was to move from an empirical measurement to an analytical prediction technique.

An area feeding into this prediction technique is "complexity." Initially the committee looked into the complexity versus reliability area. For this a working group used nine representative guided missile projects to get examples.

Examples needed were: methods of operation used in the three services; three main classes of missiles, air-to-air, surface-to-surface, surface-to-air; various stages of development and production for missile program maturity.

Also, key mechanical elements covering functional items such as hydraulic, propulsion and movable surfaces were tabulated.

From these data an evaluation of in-flight missile reliability versus electronic complexity was made. It showed a decrease in reliability with an increase in number of electronic parts.

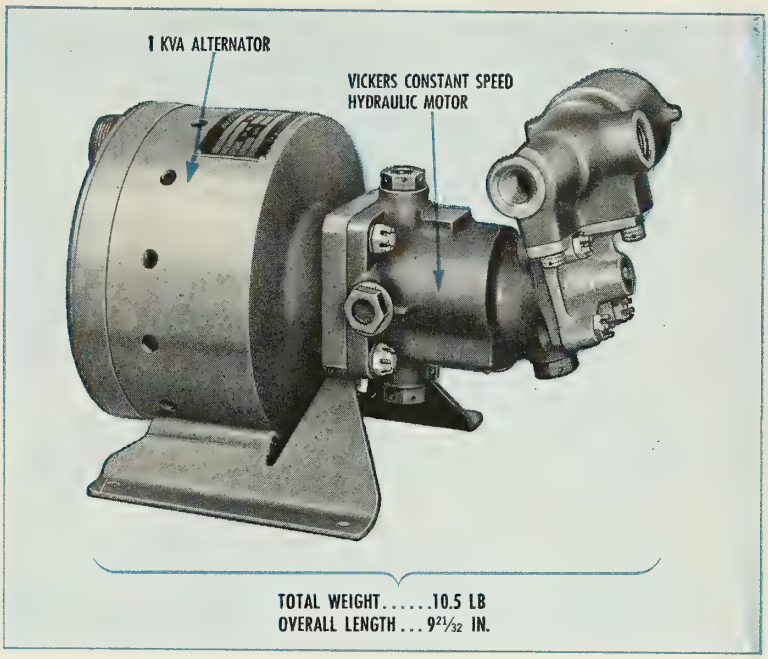
Although the data showed a missile with 200 electronic parts has a reliability of about 83 percent against about 75 percent for one with 3,000 parts, this may actually represent a measure of missile program maturity rather than reliability, Bender said.

On mechanical complexity versus reliability, the OASD group has been unable to correlate complexity with missile program growth or missile environment. This may be because mechanical designs are more reliable or mechanical failures are easier to isolate and correct before flight.

Research in these matters is new and the committee is continuing its data collection work. Already, however, some benefits have come from the work. Bender reported that several large missile makers have reviewed and reorganized their reliability program as a result of these findings.

Full publication of a consolidated report on findings of the Department of Defense Advisory Group on Reliability of Electronic Equipment is expected early in 1957.

According to J. M. Bridges, Director of Electronics, OASD (Eng) publication of this report will represent the most complete and valuable analysis of the major phases of a reliability program ever compiled.



This should provide a basis for numerical analysis and control of reliability from design to delivery.

New Vickers Airborne Electrical Power Package

. . . *Saves Weight and Space*

Utilizes the Hydraulic System for More Efficient Production of AC Power

This new isolated electrical power package provides closely regulated AC power with minimum weight and envelope while drawing its power from a hydraulic system. In new designs or when adding electronic equipment to aircraft designs in which the electrical system is already loaded to capacity, this versatile package provides the needed AC power from flow available in the hydraulic system. This generally is permissible without system change as the full flow is seldom demanded except for a few seconds under rare circumstances. Even in such cases, full flow can be guaranteed to these hydraulic functions through the use of a simple priority valve which starves the AC power package momentarily.

Less Weight and More Efficient

Important weight savings are achieved through the use of this package instead of an inverter which may also require an increase in the DC generator and line capacities. In one instance, the 10.5 lb 1 kva package replaced a 38 lb inverter for co-pilot instrumentation. An additional advantage is that the package has 62% overall efficiency while that of the inverter was 35-40%.

Extreme altitude operation is no problem as the Vickers isolated electrical power package contains no brushes or other altitude-sensitive components.

Features of AC Generator

The permanent magnet type AC generator has excellent life and reliability. It requires no bulky voltage regulator . . . is inherently smaller and lighter than conventional generators due to the elimination of the exciter and slip rings. It also has higher overall efficiency resulting from elimination of all excitation losses. Additional advantages are that the permanent magnet is unaffected by momentary short circuit, or separation of field and armature without keeper, or by temperature cycling. It is also not susceptible to aging or shock. This unit is 120/208 volt, three phase, wye connected with 400 cps at 8000 rpm. It is capable of continuous duty under environments of 0-55,000 feet altitude and ambient temperatures from −65 F to 250 F.

Hydraulic Motor Drive

The generator is directly driven by a Vickers Constant Speed Hydraulic Motor having fixed stroke and an integral flow control valve that maintains an 8000 rpm speed setting within ±2½% regardless of the load (as long as valve inlet pressure is greater than load requirement). For the unit shown above, maximum operating pressure is 3000 psi while rated output of 1 kva requires operating pressure of 2200 psi. Special configurations will maintain 400 cps frequency within ±0.1% regardless of load. This motor has a very high horsepower-weight ratio and its overall efficiency exceeds 92%. It is a time-proved design capable of many hundreds of hours of continuous service without attention.

Many Uses and Sizes

The applications for this isolated power source are numerous. For multi-engine aircraft, its use for co-pilot instruments provides dual reliability. This package has been used to supply controlled frequency AC power in emergencies when the only source of power in the airplane is a ram air turbine driven pump. The efficiency of this arrangement minimizes the size and weight of the ram air turbine necessary to provide emergency hydraulic and electric power. 7492

Now available in the sizes listed below, larger packages can also be supplied from existing components. Vickers is prepared to develop the package best suited to a specific need. For further information, write for bulletin A-5213 or get in touch with your nearest Vickers Aircraft Application Engineer.

Vickers Airborne Electrical Power Packages

kva output	weight, pounds
0.5	7.0
1.0	10.5
1.5	12.5

CENTURY MODEL 409D RECORDING OSCILLOGRAPH

Numerous agencies engaged in the manufacture and evaluation of missiles have turned to the Century Model 409D Recording Oscillograph as a reliable means of collecting missile performance and control data.

On-board mounting eliminates the necessity for the costly and often not reliable RF link.

The ruggedness and reliability of this 12-channel oscillograph have been demonstrated many times. One agency reports having recovered 42 satisfactory record rolls out of 43 firings. Another, using special mounting configuration, reports recording at 60 G's without damage.

This 13 lb. instrument is compact enough to be installed in most missiles and all electrical connections including remote control are accomplished through a single multi-pin AN connector.

Air Associates Renamed; Builds *Vanguard* Control Timing Computer

Air Associates, Inc. of Teterboro, N. J. has been reorganized under the new corporate name of Electronic Communications, Inc. and will shift its headquarters to a 75-acre site near St. Petersburg, Fla. later this year.

The name Air Associates will be retained, but only as the identity of an aviation supply division of ECI.

President Frank W. Godsey, Jr. said the new corporate name will reflect a redirection of the company's aims. As part of this program, Dr. Donald D. King, formerly of Johns Hopkins Radiation Laboratory has joined ECI and will head a new laboratory being built in Baltimore.

Dr. King and staff will direct their efforts toward electronic countermeasures research, fire control system studies, infrared work and related military electronics research of an advanced development nature.

The new emphasis on electronics is an outgrowth of past Air Associates activities at Orange, N. J., including the Navy *Vanguard* satellite pilot-computer, a device to be used for injecting the *Vanguard* into its orbit.

GODSEY

Electronics Communications, Inc. builds the coasting-time computer that will control timing of *Vanguard's* second stage jettisoning and ignition of the third stage.

The first computer will be delivered to the Martin Company in March and additional units will follow in line with the launching schedule.

Task of the computer is to gather flight data up through the second stage rocket's thrust period. From these data the device will compute correct coasting time between the end of this period and the operations which follow it.

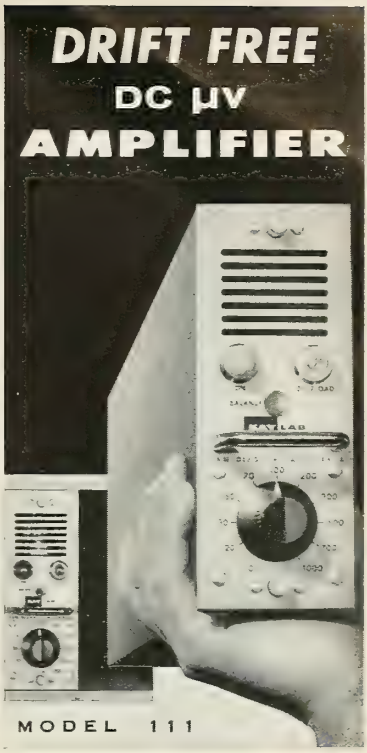
Astrionics

By Henry P. Steier

Today has been called the "solid-state electronics era." In this issue of m/r Frederick Ordway notes what can be done with small research rockets. He says, "Today it is amazing what can be done with relatively low payloads of 25-50 pounds." It can also be said that the major portion of research rocket capability would not be where it is without the new science of—solid-state electronics.

The great amount of information today's rocketeer gets out of a very small instrumented rocket can be credited to the circuit engineer's early cognizance of the electric, magnetic and photic properties inherent in the new tiny, lightweight, low power consuming offspring of solid-state physics now taking the field. From talks and boosted attendance at the 1957 Transistor and Solid State Circuits Conference in Philadelphia last month came strong indication of early application.

Not so long ago the low input impedance and low voltage breakdown of semi-conductors was a real application hurdle. Engineers are finding a way out though. Now RCA has a bootstrapped collector emitter follower circuit that gives a 105-volt sweep generator signal. The follower has an unheard-of input impedance of 100 megohms. General Electric is using multi-holed ferrite core "transfluxors" as a means of digital to analog conversion. They are used as a combined memory ac gate and can be obtained from RCA at 50¢ each.



A counting circuit by Bell Telephone Labs. uses a ferroelectric capacitor that acts as a battery and switch in series. Depending on the capacitor charge the switch opens and closes. Two of the ferroelectrics in a particular circuit can simulate a "ladle and bucket" effect so that a count is not transferred until the second ferroelectric gets a given number of pulses. The device uses a barium titanate crystal and is in limited production by Hershel Chemical Co., Cleveland, Ohio. The IRE Professional Group on Circuit Theory proceedings covering the conference ought to give circuit engineers a lot for the money.

•

Western U.S. users of National Bureau of Standards for obtaining a calibration service of their instruments against national standards will get much better service in 1957. NBS is building a $2 million center at Boulder, Colo. to perform calibrations on instruments and components ranging from direct current to 40 kmc devices. Eventually a calibration service up to 100 kmc will be added.

•

Latest contribution to research missile data acquisition is RCA's AN/FPS-16 instrumentation radar. Availability of production units of the new system in December 1957 should improve instrumental accuracy by a factor of ten over available units and permit immediate reduction of data without manual operations or film processing. Space-time data will be obtained as direct digital read-out and be as good as, or better than, theodolite data. The FPS-16 is third of a series of radars for missile work by RCA. Others were the Bumblebee radar developed jointly by Johns Hopkins Lab. and RCA, and the Terrier radar for Army use of the Navy *Terrier* missile. RCA's prototype of the AN/FPS-16, the XN-2 will track *Vanguard* when it takes off.

The **KINTEL MODEL 111** amplifier provides the lowest drift of any commercially available broadband d-c amplifier. The unique circuit incorporates **KINTEL's** proven chopper amplifier system to provide unsurpassed dynamic performance—unaffected by load or gain changes. Available in a single-unit cabinet or a six-amplifier rack-mountable module only 19 inches wide, the **Model 111** is ideal for data reduction facilities, or as a strain gage amplifier, recorder driven amplifier, or general purpose laboratory amplifier.

SPECIFICATIONS

- ± 2 uv equivalent input drift

ROY MARQUARDT, at 39 is the youngest chief executive officer in the aircraft engine business. A graduate of the California Institute of Technology, he was Director of Aeronautical Research at the University of Southern California prior to founding Marquardt Aircraft Co. in November, 1944.

Marquardt offers Engineers an opportunity to grow with the company!

Engineers looking for a company to grow with, should look to Marquardt Aircraft Co. Here is why!

Under the guidance and leadership of Roy Marquardt, an engineer-president, Marquardt has become the undisputed leader in the field of ramjet engines—the powerplant of the future".

In just twelve short years, the company has grown from one man's idea to an engineering and production facility employing more than 2,500 people.

But most important, Marquardt engineers have grown in skill, scope and professional ability along with the company's many exciting and rewarding projects.

Within the next two years, Marquardt will more than double its manpower. Even with this new increase in personnel, engineers joining Marquardt now will have this same opportunity to grow with the company.

For engineers in almost every specialty—from production engineering and qualification testing to advanced research in hypersonic propulsion—Marquardt means opportunity.

Today is the day to write that letter to: Jim Dale, Professional Personnel

Aerophysics

By Seabrook Hull

Confusion over what the Army's IRBM *Jupiter* did or did not do on firing day, March 1, at Patrick AFB may be explained by the fact that two were fired. Three missiles were supposed to have been tested. One is reported to have been a Northrop *Snark*. From a reliable source this column hears that the other two were *Jupiters*—that one left the atmosphere and was 60-to-70% successful before malfunctioning near the end of its firing period, that the other apparently tipped off course and had to be exploded not far from Delray, Fla., about 40 miles from Patrick. Neither was carrying operational guidance gear. In any case, members of ABMA's Redstone Arsenal team are highly gratified with the results and are busy readying the next *Jupiter* for test.

The ability to study the thermodynamics of hypersonic flow has received a terrific boost with the announcement of Dr. Gabriel Giannini's 10,000°K plasma jet and GE's MOSD's water stabilized arc that has officially achieved temperatures of 14,000°K and a heat transfer rate of 2000 BTU per square foot per second. Unofficially, this device is credited with a heat transfer rate of 6000 BTU. These rates exceed by wide margins ICBM requirements.

•

Dr. Edward Van Driest, NAA, participating in the space flight symposium emphasized the importance of design to reentry, whether by a satellite, space vehicle or ICBM warhead. The heat transfer rate through a turbulent boundary layer exceeds that through laminar flow by a factor of 10. Significantly, the advent of turbulent flow is delayed by cooling the nose cone. Van Driest also reported that boundary layer sensitivity to surface roughness apparently decreased with increasing Mach number.

In this same field, Dr. Fred Riddell, AVCO Research Laboratory, noted that in checking heat transfer theory against actual shock tube experiments, agreement between the two was good. He suggested that proper design precautions might enable the *Vanguard* satellite to survive reentry intact.

At Washington, D. C. Dr. J. H. Doolittle, Chairman of the National Committee for Aeronautics announced that NACA research rockets have "attained somewhat higher speeds" than the Mach 10.4 (6800 mph) revealed at last Fall's Langley Laboratory inspection. These new tests have, in fact, achieved 8000 mph. NACA is in the process of developing rocket techniques for in-flight study at between Mach 20 and Mach 30—up to 20,000 mph.

NACA this year is asking Congress for $41.5 million for new research facilities, 50% of which will be for hypersonic study equipment, including a hypersonic physics test plant to cost nearly $2 million.

•

An uniquely designed gyro-compass capable of rotational speeds up to 30,000 rpm utilizes a single airbearing instead of the six conventional ball bearings, detailed in Commerce Department's Office of Technical Service's report number PB 121405 translated from a 1954 German paper on Water and Air Bearings with Pressure Lubrication.

•

The area of contribution of the Vanguard Satellite during IGY will be confirmation and expansion of data from altitudes between 30 and 150 miles and the supply of entirely new data from 150 miles to possibly 1,500 miles.

ENGINEERS, SCIENTISTS:

What did they say the last time you had an

IDEA?

At Decision, we talk to hundreds of engineers, and many report how frustrating it is when they make a good constructive suggestion and are gently reminded that "ideas" are the responsibility of others. (Strangely enough, these same companies often talk about "creative engineering" in their recruiting ads.) Fortunately this attitude is not typical of most progressive companies today.

We know many companies who encourage and appreciate creative thinking . . . who know that youth, inspiration and progress all go together.

Whether you're thinking seriously about changing jobs or not, Decision can improve your job perspective *confidentially* and at no cost to you. We will send reproductions of your resume (without your name) to the hundreds of top ranking firms—our clients—who pay us to find good men. And, we will enter your name and resume in our unique Decision/Register, which we search daily to find engineers for specific job openings.

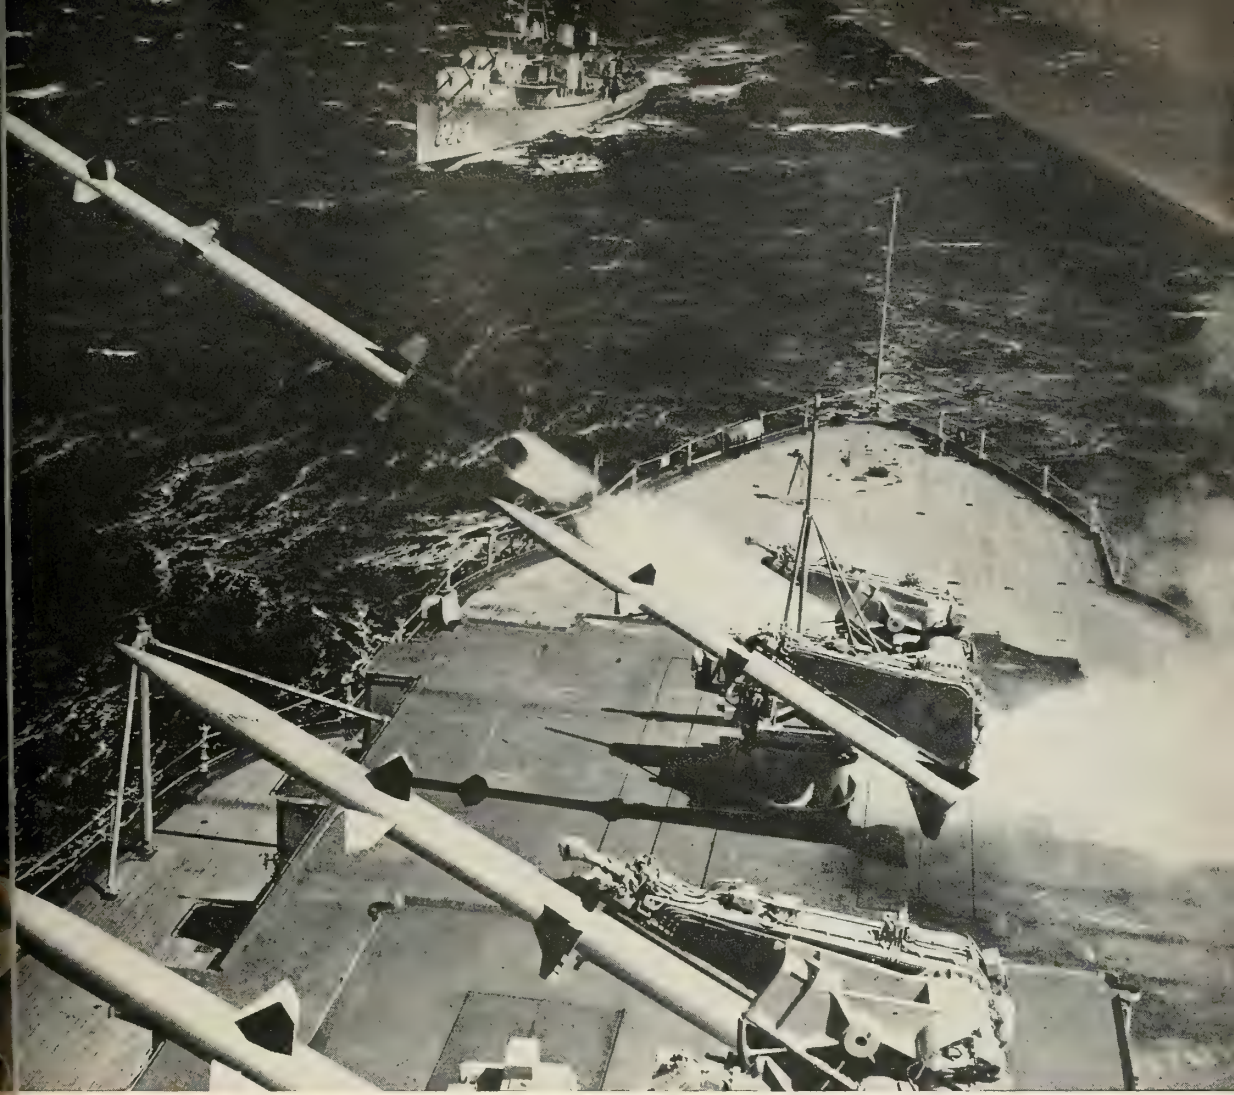
International Scene

By Anthony Vandyk

The British Army's first guided-missile regiment is being formed this month at Aldershot, the nation's traditional military base. Equipment for the new unit is the *Corporal* which is being procured in the U.S. Since the U.S. is not allowed to sell fission of fusion warheads nor to release any information about their design, the *Corporals* will be supplied to Britain without a warhead.

The next phase in the development of France's Trident fighter will be the elimination of the pilot. Remote control will be used to bring the pilotless rocket-powered aircraft back to base after it has launched its missile. The final stage in the "missilization" of the Trident is likely to be the transformation of the model into a VTO vehicle. The project is now being conducted by Sud Aviation which has been established to take over the operations of Ouest Aviation and Sud-Est Aviation. The Trident was developed by Ouest Aviation.

Cooperation between the British and French industries in the missile field is likely to increase very markedly. The French missile range in the Sahara desert could be made available to the British industry thereby cutting down the need for sending guided weapons all the way to Woomera in Australia for testing. Britain's coastal facilities are inadequate for all but the most elementary short-range launchings.



The Japanese government has requested the U.S. to supply seven types of missile: *Honest John, Nike, Terrier, Sparrow, Bomarc, Talos* and *Falcon*. It has not been made clear which of these guided weapons will in fact be supplied although the Department of Defense has agreed to let the Japanese have "certain unclassified equipment" including guided missiles for R&D purposes.

It's no secret that Sweden's only airframe manufacturer, Svenska Aeroplan AB, is very active in the missile field. It was recently disclosed that SAAB has been working on missiles since 1946 when the design of an "air torpedo" for the Swedish navy and the government's Board of Inventions was started. Another Swedish company, STAL, was also involved in this project which had its share of initial teething troubles. The first completely successful firing finally took place on June 3, 1947 at the Karlsborg experimental station on Lake Vaettern. The missile used a pulsejet engine developed by STAL.

There is high hope in Britain for the de Havilland heat-homing AAM which has been developed in conjunction with the Mullard electronics company. *The Economist* says: "After a period during which it was as easily distracted as a puppy, it has now grown into a well disciplined and reliable hunter." The British paper contends that the de Havilland missile "has an edge over its American counterparts."

Main contenders for French AAM production contracts are Matra and SNCA du Nord. The former company's position has been strengthened by the conclusion of an agreement of cooperation with the Floirat group which includes Breguet and RBV-RI. Breguet is a major airframe manufacturer while RBV-RI is an important electronics company. Both are headed by one of the most dynamic men in French aviation—Henri Ziegler, a former president of Air France.

That old bogey security is impeding European companies in their efforts to determine the market for their missiles. The British industry is able to furnish virtually no information to its NATO allies and to members of the British Commonwealth. The success of the British industry in the export market since WW II has been largely due to foreign sales of military models—mainly fighters. Unless the missile can take the place of the fighter, Britain's exports will suffer.

Terriers are launched from the Navy's guided-missile ship, U.S.S. *Boston*. In flight, Terrier homes unerringly on target. Missile is providing Navy with up-to-date air defense against attack.

AIR FLASK FOR A TERRIER

· the "Terrier"—the Navy's surface-to-air guided missile—ALCO pro-
es the critical air flask which supplies pressure to guide the missile's
ht-control surfaces. With this aid, the Terrier tracks and kills no
tter what evasive action is taken. ALCO also builds Jato shells for the
ny's "Honest John," and rocket boosters for the Air Force "Snark."

O's success in missile components is drawn in large part from its broad
erience in defense production—over $700 million in the past five
rs alone. Metal-fabricating skill from over 100 years' experience,
thermal and mechanical know-how that have made ALCO a leader in
er products, also play key roles in the company's missile production.

O can help in your missile program with this broad experience and
its extensive manufacturing facilities. We'd like to send you a
of our brochure, "What Does it Take to Make a Missile?" which
ines ALCO's qualifications fully. Write Defense Products, Dept.

OUT and SAFE!

EMERGENCY ESCAPES FOR HIGH PERFORMANCE A/C CREWS!

FROM GROUND LEVEL—TO A/C PERFORMANCE CEILING

The men who challenge nature's greatest forces in today's high performance aircraft will soon have emergency escape protection from ground level to aircraft performance ceiling. Ejection seats will be equipped with a Rocket-Catapult* recently developed and produced by Talco.

Sled tests have proven that this unique design of a canted rocket thrust in conjunction with catapult ejection can reduce deceleration to tolerable limits, increase clearance of tail assemblies, stabilize seat attitude and give complete "on the deck" escape capability. With only minor modifications, the new Rocket-Catapult* is effective for the full performance range of any high performance aircraft.

The Talco Rocket-Catapult*, having the same mounting provisions, can be readily installed in all aircraft equipped with conventional catapults. Variations of this basic, proprietary design are being completed for many advanced aircraft.

Talco experience in ballistic and cartridge actuated devices can provide new approaches to the solution of many problems, on the ground and in the air, with fast, sure action in milli-seconds from "Packaged Power" units.

In sled tests at .73 Mach, conducted at Edwards Air Force Base, the Talco Rocket Catapult* carried a man-seat mass to approximately 60 feet in a stabilized trajectory for a normal parachute deployment and landing. In other ground level tests at zero velocity the man-seat mass was ejected to a height of approximately 220 feet, again, with full parachute deployment and a normal landing.

After the catapult tubes separate, the rocket contained in the inner tube provides a continuing thrust through the center of gravity of the man-seat mass, providing forward thrust to counter air drag and upward thrust to insure aircraft clearance at high speeds and sufficient ejection height for a complete "on the deck" escape capability.

Engineers interested in this exciting new field are invited to contact us.

Bristol Super Ramjet Makes Good

THE STORY OF the troubles and triumphs of the Bristol Aeroplane Company in evolving ramjet test vehicles has been released by the British manufacturer. To date Bristol has produced well over 200 *Thor* ramjet-powered test vehicles. They are rocket-boosted from standstill to speeds of over 1,000 mph in a few seconds during which time the *Thor* must light up and attain full power from a cold start. In this respect 100% reliability has been achieved.

The requirement was for a test vehicle with the following qualifications:

1—The ramjet was to be of flexible layout so that ready alterations could be made to the entry, burner, and to the tailpipe.

2—The telemetry transmitter had to be housed away from the ramjets where it would not be affected by vibration. The telemetry equipment had to be easily accessible.

3—Adequate space was to be allowed for installation of various fuel control systems for flight test.

4—It was important that the diameter of the ramjet did not exceed the maximum which could be bench tested over a wide altitude range.

These requirements were met by using twin 6-in. ramjets mounted outboard on each side of a center body in which the telemetry, fuel tank, fuel control and expulsion system were housed.

Fuel supply to the ramjets was effected by compressed air and controlled at a constant pressure by an air blast valve and a fuel pressure valve. The fuel was stored in a flexible bag situated in the tank forming the nose of the vehicle, and compressed air released from a pressure bottle in the front section of the center body, forced the fuel out of the bag along feed lines to the combustion chamber fuel jets.

Bristol fitted damping plates to the ramjets in one of its experimental test vehicles to raise the critical flutter speed well beyond that encountered in current operating range.

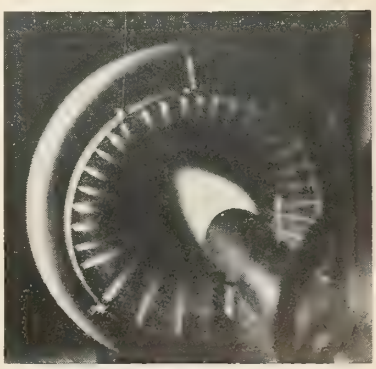
To accelerate the test vehicle up to the speed at which the ramjet engines begin to function, a cluster of cordite boost motors was used. One of the first problems which had to be faced was the separation of the exhausted boost motors from the vehicle without upsetting its flight path.

The first test vehicles had dummy ramjets and were fired to investigate the structure, stability and boost separation mechanism. Initial tests showed flutter and later, at Mach 1, instability which resulted in structural failure. Structural modifications were undertaken and a stable configuration was achieved. During these tests flight times had to be curtailed to five seconds owing to the limited size of the firing range.

As a result of the information gained from these dummy runs, Bristol produced a further redesigned version of the vehicle, influenced mainly by the major consideration of drag reduction.

By June 1950 the final design of the new vehicle had been completed, and drawing work for the launcher and loading trolleys was in progress.

The first flight of the redesigned test vehicle confirmed the accuracy of the theoretical drag estimates, showing a considerable reduction. By the end of September, two live rounds and five dummy rounds of the new vehicle had been fired, one of these being fitted with telemetry equipment. The first live round met with partial success—in both cases the ramjets fired, but were extinguished just before boost separation.



By the end of the year several more "hot" rounds had been fired to investigate light-up techniques. Some aerodynamic instability was experienced during the boost phase, but was cured by re-positioning the boost motors farther forward in relation to the vehicle. A redesigned separation gear was also adapted. This was an aerodynamically cleaner arrangement and allowed high speeds to be reached before separation of the boost motors.

During a continued study of light-up techniques, two short-range hot rounds were fired, and significant results were obtained from the second of these during the boost phase—one ramjet extinguished at about Mach 1 but the other continued burning until Mach 1.3 was reached, and telemetry readings indicated that it gave thrust. It was discovered that most of the trouble had been caused by interference to the airflow into the ramjets during boost separation. Telemetry recordings in "cold" ramjets showed a sudden drop in internal pressure at the time of separation, enough to cause the flame to be extinguished. As a result, it was decided to adopt a tandem boost configuration placed aft of the centre body, and between the ramjets.

However, success with the tandem boost brought on a new problem. More powerful boost motors were now being used, giving the vehicle an acceleration of over 20g and a velocity of 1,220 mph at separation. At this speed a completely new type of flutter was experienced. At that time flutter was known only on the wings and tail surfaces of an aircraft, but in the case of the ramjet test vehicle it was found that the greater fineness ratio of the body made possible a further type of flutter, in which the whole body was seen to flex at a fairly low frequency. The telemetry bay was therefore stiffened on all subsequent rounds and damping plates were attached to the ramjets. Theoretical investigation had shown that these measures would raise the critical flutter speed well beyond the operation range, and Mach numbers of 1.8 (1,350 mph) were later achieved without any recurrence of the trouble.

On July 19, 1951, the first objective of the program of ramjet development was reached. A short-range live round flew successfully. This success marked the first sustained supersonic flight to be made by a British designed and built ramjet powered missile.

By 1952 the test vehicle had served its purpose, and the program was brought to a conclusion. It reached the stage where it had provided a valuable means of flight testing and proving the components of a ramjet engine. ★

Much of the development program for Bristol's THOR ramjet was carried out with the aid of ground test rigs. Here water sprays quench the flame of a ramjet on test.

World Astronautics

By Frederick C. Durant III

Last year a symposium on the scientific uses of earth satellites was held at Ann Arbor, Michigan, under the auspices of the Upper Atmosphere Rocket Research Panel. Invitations were limited to authors from universities, government laboratories and selected research institutions. No press or contractors were invited. Thirty-one proposals for on-board instrumentation met initial screening requirements by the Technical Panel on the Earth Satellite Program and were referred to a working group in internal instrumentation for study and recommendation. This was much more than enough for the IGY program, which is still limited to six launchings.

Proposals were assessed on the basis of (1) scientific importance, (2) technical feasibility, (3) competence of source and (4) necessity to the proposed work of a satellite vehicle. The proposals covered ten specific subjects to be measured internally: UV and soft X-rays from sun, meteoric impacts, cosmic rays, cloud cover of earth, extreme solar UV radiation (500A), electron density of ionosphere, atmospheric density, geomagnetic field, auroral radiation, and galactic radiation. Priorities have been juggled in accordance with the scheduled development of instrumentation to meet environmental, power and weight requirements.

Press of time in preparing for the IGY satellite program, has prevented the Academy of Sciences from wider solicitation of suggestions for (1) kinds of satellite measurements, (2) measuring techniques to be used and (3) design of measuring equipment capable of meeting the extreme weight and dimensional limitations of the satellite payload. It may be that many important concepts and ideas have not been forthcoming because the basic problems themselves have not yet been brought to the attention of researchers here as well as abroad.

The IGY satellite program will be a single series of launchings. But most authorities expect this program will be followed by others, after the IGY has been concluded because of the demand by scientists for more extensive data obtainable in no other way. IGY satellite data will be limited and fragmentary. Some data will be in support of theory, other data will be paradoxical and unexplainable. Further, more extensive, measurements will be required.

Why not set up the mechanics and organize a long range program now, to be carried out under less pressure and with more thought than is possible for the IGY program? Such a program would appeal to those researchers who are repelled by deadlines. It would also offer an opportunity to tap the knowledge of brilliant scientists outside the United States. Research funds spent in such a way would be more efficient than in the current "crash" program.

From East Germany comes a report that a Soviet scientist is working on a preliminary design study for an unmanned, non-returnable reconnaissance rocket to orbit Venus. The planet would be TV-scanned and images transmitted to earth. The Venus "probe" would be launched from earth orbit of 22,000 miles. The rocket would be fueled by five "ferry" rockets (presumably manned) and make the trip to Venus orbit in 146 days.

•

Italy has nearly completed outfitting the cruiser, Garibaldi, with missile launchers in anticipation of operational surface-to-air missiles. Minister of Defense Taviani has also announced that Italian air-to-air missiles are being developed.

Space medical research is being undertaken by the Italian Ministry of Defense at the Research Center of Aeronautical Medicine. According to a recent report, test apparatus has been built to study subgravity conditions for short periods of time.

To the ENGINEER of high ability

Through the efforts of engineers The Garrett Corporation has become a leader in many outstanding aircraft component and system fields.

Among them are:

air-conditioning

pressurization

heat transfer

pneumatic valves and controls

electronic computers and controls

turbomachinery

The Garrett Corporation is also applying this engineering skill to the vitally important missile system fields, and has made important advances in prime engine development and in design of turbochargers and other industrial products.

Our engineers work on the very frontiers of present day scientific knowledge. We need your creative talents and offer you the opportunity to progress by making full use of your scientific ability. Positions are now open for aerodynamicists ... mechanical engineers ... mathematicians ... specialists in engineering mechanics ... electrical engineers ... electronics engineers.

AiResearch Cabin Air Compressors

Latest designs will soon appear on the most modern turbo-jet (unit shown) and turbo-prop air transports

Cabin air compressors by AiResearch are turbo-driven, shaft-driven or hydraulically-driven. They provide cabin airflows up to 60 pounds per minute at 40,000 feet, with pressure ratios up to 4.3. Their dependability and durability have been service-proved by the most extensive experience in this field — 4000 of these units are now in operation.

These compressors are integrated into complete air conditioning systems. The utmost compatibility is assured, since AiResearch manufactures every component and has experience in every problem of interrelationship between components. We have assumed complete system responsibility in this field for many of America's finest present and projected airliners.

Whether your problem involves components or complete systems, we invite your inquiries.

Outstanding opportunities for qualified engineers. Write for information.

32 to 8,000 pictures per second with the newest high-speed motion picture camera

The Fairchild Motion Analysis Camera System, completely light-weight and portable, designed with the aid of the men in the field for today's instrumentation and research needs. The Fairchild MAC features:

- —A 10 lb. camera, suitable for handholding.
- —A 4½ lb. field power supply, smaller than a cigar box.
- —Camera and event synchronizer (a-c or d-c), the size of a large briefcase.
- —A tripod that folds down to a length of 16".
- —Lighting equipment, minimal size, portable.
- —A complete family of ruggedized lenses from 3.7 to 254 mm and auxiliary optical equipment which includes fiducial markers and means for making combined oscillographic and high-speed motion pictures.

Performance:

- —The widest speed range available, covered with easily interchangeable motors.
- —Unrivalled picture steadiness and sharpness.
- —Stop-start operation up to 450 pps.
- —Capable of withstanding severe environments of vibration, acceleration or shock.
- —Color film without color correction filters.
- —Simplest loading and operation.

Cost:

- —The camera with any lens from 13 to 154 mm. focal length and any single motor is only $1,190.00.

For full information on the camera and complete system plus latest data on high speed photography, mail coupon today:

How research rockets will tackle

The Conquest of the Moon

. . . and tell us what's on the other side

By Erik Bergaust

SEVERAL OF THE 10 ARDC centers are expected to synchronize their exploratory research activities shortly for the forthcoming USAF lunar rockets.

Although no decision has yet been made as to which moon rocket will come first, it is anticipated that it will be decided as soon as our ICBMs become ready for flight testing, i.e. within one year, and as soon as super-propellants and especially tailored control systems become available. Possibly two years later the first lunar rocket launching will be attempted. So one clear night, when weather conditions are perfect for the first firing, specimens of our intercontinental test missiles will zoom aloft from Patrick Air Force Base in Florida.

Under the impetus of its powerful, roaring rocket engines, the 80-90 foot missile will hurtle through the dense lower layers of the atmosphere. Some 30 miles up, the main stage of the rocket will have burned out and be jettisoned. A smaller bank of engines in the second stage will push the space vehicle on into interlunar space. Only a few minutes after blast-off the rocket will have reached escape velocity and in a matter of four days the vehicle will have made it to the moon, some 250,000 miles away.

The ambitious missile scientists behind the lunar rocket proposals feel the projects won't be too difficult to undertake. Of course, for centuries man's limited technology has ruled out "the trip to the moon" as something inconceivable, something for dreamers and storybook authors only. But not so today. Most scientists seem to agree the splitting of the atom actually was a far more difficult task than to send a rocket to the moon. Says one lunar rocket engineer: "The moon rocket is inevitable. There's not a question any longer of how to do it, but when. And this question has its answer in the availability of our ICBM engines."

"Even a redesigned *Vanguard* vehicle might have lunar capability," another rocket scientist says.

The gravity pull of the earth is significant enough to slow the rocket down on its way into space, but not sufficient to stop it. As the rocket approaches the moon, another gravity factor becomes involved, namely the pull of the moon itself. So the rocket will start to pick up speed again after having passed the "neutral" point where the gravity pull of the earth and that of the moon are in balance.

As the lunar vehicle comes in closer to the moon's surface and accelerates faster and faster toward Luna's mystic and majestic mountains, automatic devices will trigger the guidance and rocket power needed to adjust the missile's path into an orbit around the moon. While observers with powerful instruments on earth lose track of the missile as it disappears over the rim of the moon, instruments in the rocket's nose section will begin to scan the unseen side of the moon—an area as big as the North American continent, and an area never seen by man.

During the time the missile circumnavigates the moon, scientists on the earth will have no contact with it. But suddenly, it will be registered in the observing instruments as a tiny dot coming from behind and over the moon's rim on the opposite side. Then, at a precalculated moment, the engines will be fired again and the missile will leave the moon and return to earth.

The stored information will be telemetered to the ground station in Florida and the missile might be left in an orbit as a satellite. Eventually it will probably start descending into the denser atmosphere and evaporate like a meteor or it will disappear into space.

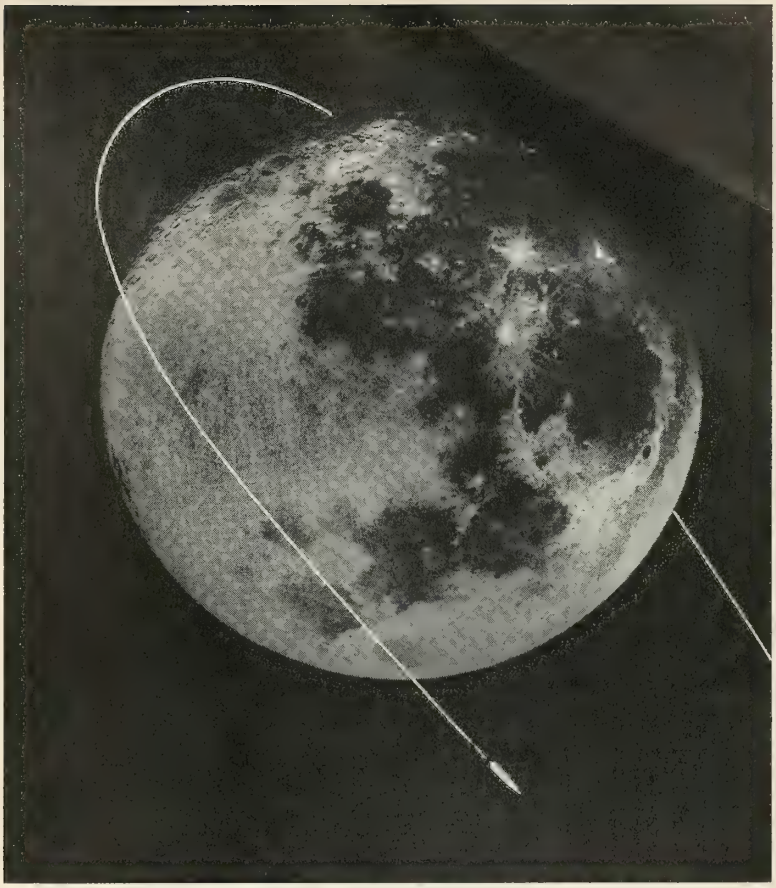
But the world's astronomers, geologists and other scientists will have obtained the most sought-after information of all time. But more important than just getting a look at the bashful side of the moon, enormous gains to science will be realized. These may include a very exact measurement of the velocity of light; determination of the

Ever since the days of the first Chinese "fire arrow" history has been sprinkled with stories on proposals for moon rockets. As revealed in our exclusive news story on page 25 we are getting close to realization of the first lunar vehicle. Here m/r details the why's and wherefore's, the significance and promise of the forthcoming Air Force venture.

residuum of an atmosphere on the moon; secondary radiation from the moon's far side; gravitational constants; microwave propagation; hydrogen clouds and drifting electrical fields.

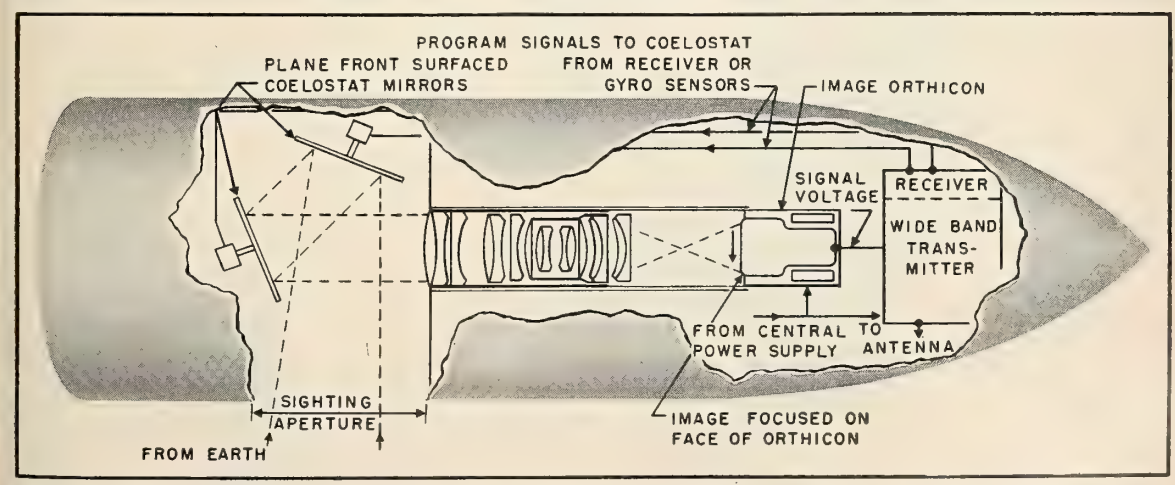
Soviets Interested Too

But the Russians could beat us to the moon. Professor G. A. Chebotarev, a doctor of physics and mathematics and a senior scientific worker in the USSR Academy of Sciences' Institute of Theoretical Astronomy, made these observations in *Moscow News* recently:



"Once the artificial satellites are created, the next step in the conquest of cosmic space will be to send 'automatic rockets' to the moon and the nearest planets in the solar system and to guide them back to the earth. Until now it was thought that such flights would require an enormous amount of fuel and that for this reason they would not be practicable at present. However, this is not so.

"The initial speed of such a rocket must be 6.8 miles per second. Near the moon this speed will drop to zero. This will make it possible for us to make observations of the side of the moon which is away from the earth. We shall be able to do this for about 60 hours with the help of various automatic devices which will be installed in the rocket," the Russian professor says.

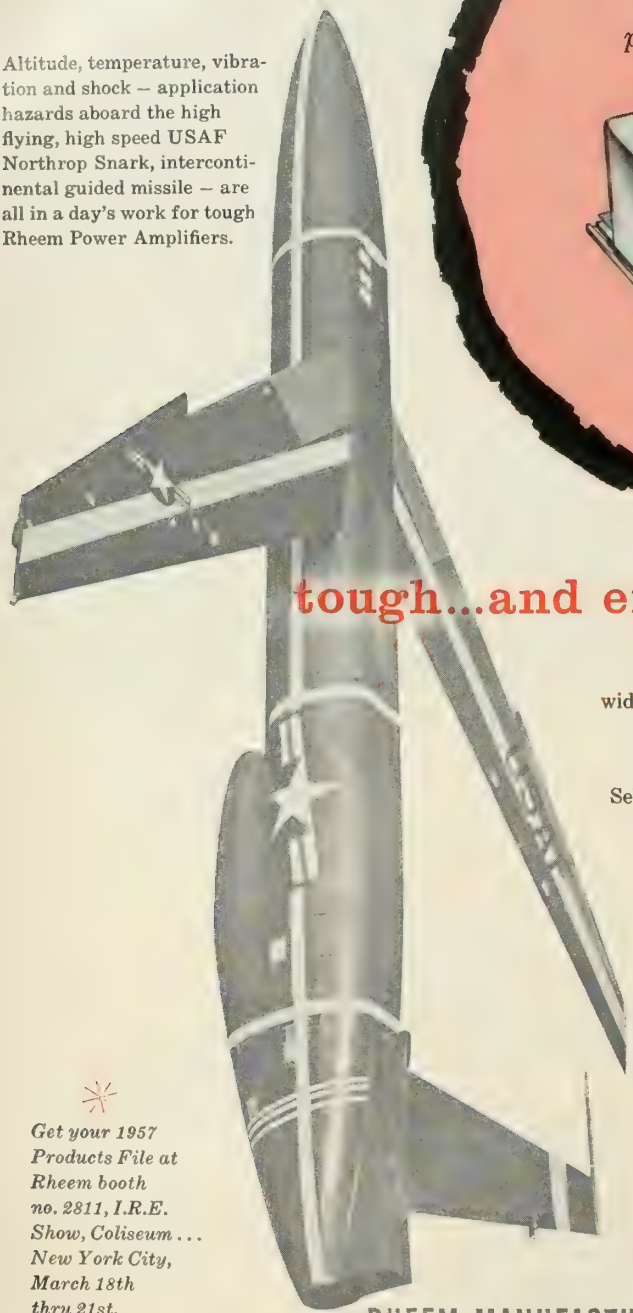


The Russians have calculated that the rocket will come within 17,932 miles of the moon. Its maximum distance from the earth will be 258,489 miles. The total duration of the flight from the earth to the moon and back will be 236.14 hours, about ten days.

At present orbits have been worked out which will allow the rocket to come within a distance of 3,100 to 3,700 miles from the moon, according to Russian scientists.

"During the rocket's return to our planet, its speed will increase once more to 6.8 miles per second. In order to retard the fall of the rocket, parachutes and gliders will be put out when it comes into the earth's atmosphere," says Professor Chebotarev. The Reds say this "new" discovery makes it pos-

According to Brigadier General Hollingsworth Gregory, man's first moon rocket may be a small instrumented vehicle designed to circumnavigate the moon and collect information of scientific value. Information on the unseen side of the satellite will be registered.



Variable focus Zoomar System television-type camera likely to be carried in the Air Force reconnaissance satellite. This video scanning system could give continuous photographs of 200,000 square-mile areas. Similar system might be employed in moon rocket. Mirrors reflect picture through telescope; orthicon unit converts picture into signals that are sent back to earth.

RHEEM REL-09

miniature RF power amplifiers

Altitude, temperature, vibration and shock – application hazards aboard the high flying, high speed USAF Northrop Snark, intercontinental guided missile – are all in a day's work for tough Rheem Power Amplifiers.

tough...and engineered to deliver

The REL-09, Miniature RF Power Amplifier, has widespread application in airborne telemetering systems. To ensure reception of high quality signals, step up the power radiated from your airborne equipment. Select the power amplifier which normally exceeds your requirements for vibration, shock, temperature and altitude. Use the Rheem REL-09 for consistent results. Power output—11 watts; Input Drive—1.4 watts. Detailed specification, price and delivery will be furnished promptly on request.

sible to say that the solution of the problem of sending a rocket to the moon and bringing it back is of the same order of difficulty as that of creating an artificial satellite of the earth.

The Other Side of the Moon

Now, what *is* on the other side of the moon? And why is it that we never see it? Of course, our moon rotates around its own axis, as do all the other planets and their moons in our solar system. Our moon, however, is peculiar in its rotational behavior.

Walk around a circular table in the center of a room, and you will notice that upon completing the circuit you have at the same time turned around once. You have faced in turn all the pictures on the walls in the room, and to do so you are bound to turn around, to look at those which were exactly behind you when you started on your circular tour. In the same way, the moon is circling around our planet, always keeping the same face turned in its direction, while completing the orbit around the earth during the course of a month.

Because it is always keeping the same face turned towards us, we can never observe the moon's other side. This absence of rotation relative to us means that the earth must remain fixed in the lunar sky, never rising or setting. Owing to a slight "wobble" of the moon as it travels in its orbit, the earth would seem to move in a small circle around its average position, but this would hardly be noticeable, except at points near the visible edge of the earth's satellite.

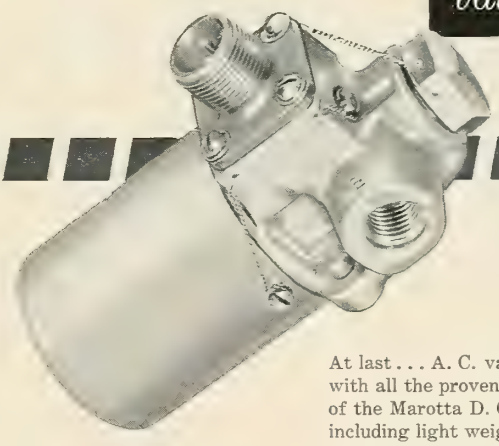
Here there would be a narrow zone where the earth would bob up and down on the horizon—and beyond this belt there would be the region where our planet is forever invisible. For some reason this is often called the "dark side," but of course it would receive just as much sunlight as the rest of the moon—nor is there reason to presume that it will be very different in other ways, scientists believe.

Despite the seeming beauty of the moon, the Queen of Night has no light of her own. Her silver mantle is borrowed sunlight. The moon is a dead world—dusty, dry and airless—according to most astronomers.

"Silence of Death Must Prevail"

"There is not a sign of life, not a tree, a flower, or even a blade of grass to relieve the dreary monotony of boundless plains, mountain heights, or of yawning chasms," a scientist writes about the moon. Not a sound can be heard on its surface; speech will be utterly useless, as there is no air to carry the sound of a voice.

"The silence of death must prevail, the absence of air must also produce startling effects in a lunar landscape, distant mountains appearing sharply outlined against a sky black as at night, their outlines only brought into sharp relief when illumined at sunrise," says astronomer Mary Proctor.



To the question "Is there life on the Moon?" most astronomers until quite recently would have returned an unequivocal "No," pointing out that the lack of air and the temperature extremes ruled out the possibility. Many astronomers still maintain this position, but a considerable number of experienced observers say they have detected changes in certain areas which suggest the existence of vegetation.

"It is by no means difficult to imagine that plant life might adapt itself to lunar conditions (some terrestrial cacti thrive in almost equally unpromising environments!) but for the present this must remain speculation," says astronomer Arthur C. Clarke.

There is no water on the moon's surface, nor the "seas" so fancifully named by Galileo, such as the Sea of Serenity, the Sea of Tranquility, the

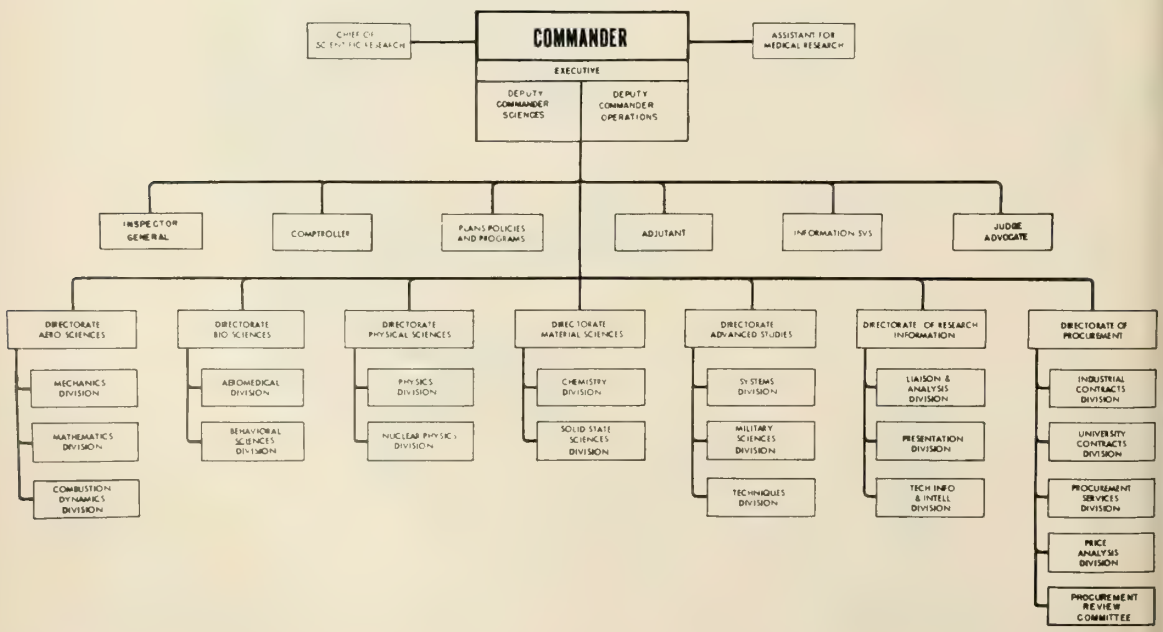
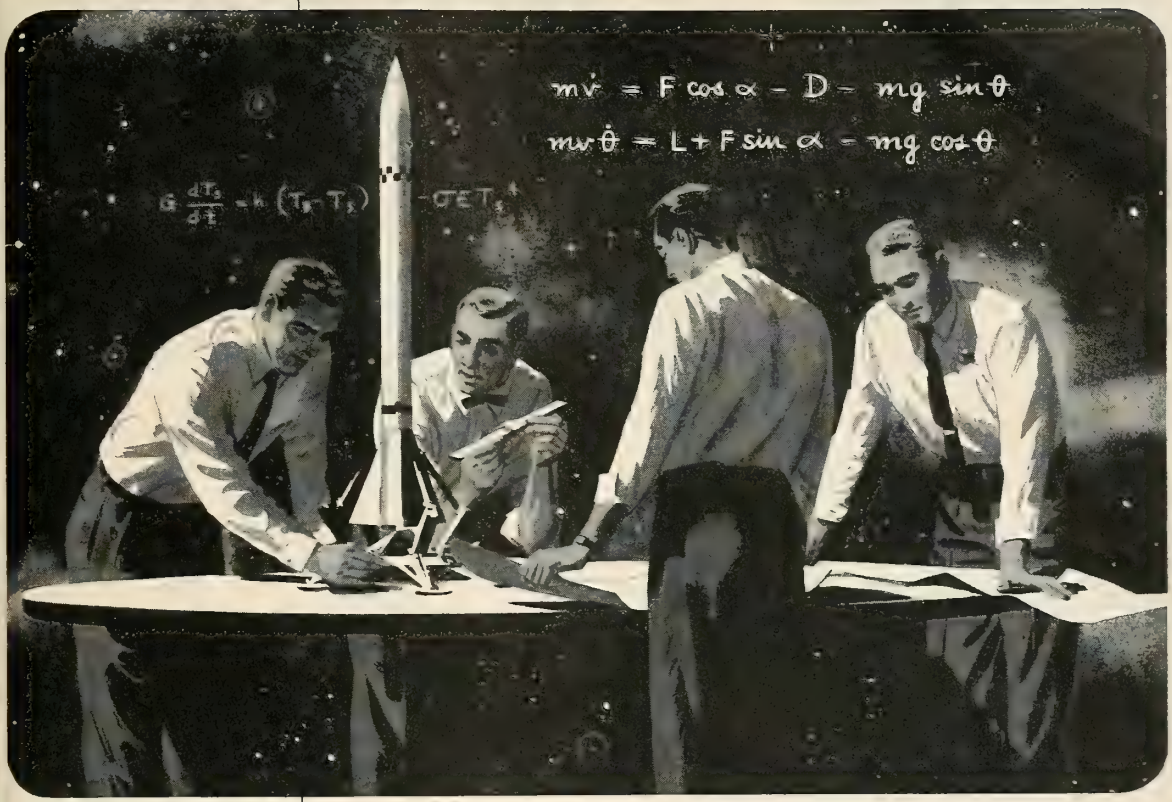
Convair, unofficially, has been mentioned as one of several companies preparing moon rocket hardware proposals. This picture shows three Convair "moon rocket" experts. Left to right: Director of Scientific Research, DR. CHARLES CRITCHFIELD; Chief Engineer, K. J. BOSSART and Preliminary Design Chief KRAFFT A. EHRICKE.



Bay of Rainbows, and others of like kind. However, these names are still retained on maps of the moon. Galileo named the greatest chain of lunar mountains after the Apennines, and this range on the moon borders on the Ocean of Storms. It extends some 460 miles, and is surmounted by a peak 21,000 feet high. Another mountain range named the Alps juts out from the Sea of Cold, and proves to be an exceedingly steep and lofty chain of mountains, one of its peaks called Mont Blanc reaching upward some 14,000 feet.



The height of many of the lunar mountains is equal to that of some of the highest on our planet. As the sun rises on the moon, the black shadows of these lofty peaks fall to a great distance as they creep across the plain below. As the sun approaches the point overhead, the shadows slowly decrease in length. At sunset on the moon the shadows fall in the opposite direction across the plains, until the mountain peaks only are illumined by the sun's light. The height of a lunar mountain or depth of a crater can be measured with considerable accuracy by means of its shadow.

Because of the moon's wobbling our researchers of the skies have been able to peek over the rim for some limited distance from time to time. What have they seen? Mountains, and more mountains. Most of them typical, ring-formed crater-type mountains, dark and cold, but impressive, spectacular.

Astronomers seem to think the rest of the moon's unseen side is filled with much of the same type terrain that can be seen from the earth. But we don't know. And since science cannot accept guesses or assumptions, since nothing but facts must prevail for our researchers in their effort to map the history of the universe we live in, tools for photographing the other side of the moon are most welcome. Only the United States Air Force can provide these tools; characteristically enough, the greatest of weapons, the intercontinental ballistic missile, will serve humanity in this research. It could happen as early as 1959, according to some engineers. By 1962 according to the Air Force's "conservative" estimate. But it *will* happen. ★

The Air Force Office of Scientific Research is in charge of the various moon rocket study contracts now being carried out. As the program progresses several other ARDC centers will become involved, particularly the Western Development Division.

Engineering Teamwork in Missile Development

The Jet Propulsion Laboratory is a stable reseach and development center located north of Pasadena in the foothills of the San Gabriel mountains. Covering an 80 acre area and employing 1700 people, it is close to attractive residential areas.

The Laboratory is staffed by the California Institute of Technology and develops its many projects in basic research under contract with the U.S. Government.

Opportunities open to qualified engineers of U.S. citizenship. Inquiries now invited.

Engineers and scientists interested in a wide range of activities will appreciate the fluid character of the research and development projects in progress at the Jet Propulsion Laboratory. These projects include research in the fields of Electronics, Physics, Applied Mathematics as well as the design, development and analysis of guided missile systems.

These men, though individually responsible, work together as a thoroughly integrated team on all of the aspects of the entire missile system instead of concentrating on certain highly specialized missile components.

Since this work includes projects involving guidance, electronics, systems analysis, structures, propulsion etc., which are constantly influenced by continuing Laboratory research, the comprehensive program contains problems which are challenging to individuals with interests in virtually every phase of engineering and science.

The great diversity of activity and constant progress being made in the various fields of endeavor by the staff of the Jet Propulsion Laboratory has proved to be a stimulating attraction to qualified people interested in pioneering in basic research, applied research and development engineering in the guided missile field. The result of this has been to bring together a congenial group of forward-looking engineers and scientists who are intensely interested in the pioneering projects now in progress at the Laboratory.

Additional men of this type are needed and if you are interested and feel you are qualified, send your resume today for immediate consideration.

Tactical Reliability—the Main Test

Combat Performance Determines Missile Quality

By Captain Patrick W. Powers, U. S. Army

AT A RECENT guided missile reliability symposium, a participant stated that a certain missile system had 14 out of 15 successful firings. Thus, it was 93% reliable, which is commendable indeed! However, judging from the murmurs of dissent from the audience, largely military, it was evident that his definition of success was not in agreement with that of the majority.

The usefulness of a missile as a weapon depends not only on its performance once it's launched but also on whether it gets unstuck at the precise time required by the military situation. Test range reliability is one thing; tactical reliability is quite another and the one, after all, that really counts.

There is a real need for a valid definition of tactical reliability expressed in explicit terms of weapon use. Reliability percentages without regard to operational firing conditions and functions don't give an adequate idea of a missile's usefulness as a weapon. Research and development firings are so different from military usage that figures are misleading.

The product of the reliabilities of critical components in a missile system is useless to the military commander in the field. He defines tactical reliability as the probability that a missile system will detonate the warhead at an effective distance from the target when he wants it—not at some random future time.

Often when discussing missile reliability we lose sight of the only military requirement for a guided missile: to get an effective warhead on target on time. The relationship between the warhead and the missile becomes, then, of critical importance and must be included in any concept of reliability.

Where the warhead detonates is broken down into a three-dimensional problem. A height of burst bracket is determined by the fuzing system and a range and azimuth error by the guidance system. The actual accuracy requirement depends on the effect desired on the target to be attacked and on the type and size of the warhead used. For some surface-to-air missiles, the guidance and fuzing systems may be combined but there remains a maximum three-dimensional miss distance outside of which the warhead will not be effective on an attacking aircraft.

A likely target for a surface-to-surface missile might be a large body of troops concentrating for a river crossing. The mission of the missile attack might be to render 50% of this mass of soldiers combat ineffective for a period of eight hours. To accomplish his mission, the commander would determine from his firing tables and warhead effects manuals the height of burst bracket and maximum miss distance to insure the proper effect on the target. Depending on the tactical reliability of the missile system and its accuracy, he might have to prepare one or more to accomplish the mission.

The accuracy or miss distance of successful missiles can be stated as a circular probable error or median radial miss distance with a maximum miss distance to include 95% of all missiles fired in the sample used. This approach will then more precisely define what is meant by a successful firing for testing and training purposes and give the commander reasonable accuracy limits on which to base his decisions for combat firings. For tactical purposes, an arbitrary miss distance is n ot valid since it would depend on the effect desired for a given target.

With a large and continuous personnel turnover, expert crews seldom

Martin Matador. It's a weapon and it's reliable only if it delivers its warhead where and when the field commander requires. In a combat situation, there is no second chance.

Trial Number	Preflight Successful	Inflight Successful	Remarks
1	No	No	Not fired; late
2	Yes	No	Fired; excessive miss distance
3	Yes	Yes	
4	Yes	Yes	
5	Yes	Yes	
6	No	No	Not fired; late
7	No	No	Not fired; late
8	Yes	Yes	Fired; third attempt
9	Yes	Yes	
10	Yes	Yes	

- *Actual Missiles Fired—7*
- *Preflight Reliability (7/10)—70%*
- *Inflight Reliability (6/10)—60%*
- *Tactical Reliability (6/10)—60%*

can be realized for an appreciable length of time. This requires reliable, soldier-usable equipment that can be operated under severe conditions.

Only combat experience will provide valid figures. A hypothetical example of the inflight reliability of a ballistic missile system based on these types of firings might be the following: success criteria—armed within 2000 meters of target; total missiles fired—10; successful missiles—6; inflight reliability—60%; accuracy—with a median radial miss distance of 800 meters and a maximum radial miss distance of 4000 meters.

Preflight Reliability

To meet a firing time, the missile system must have a high checkout or preflight reliability. Time is always of the essence in a tactical situation. The rejection rate of components that malfunction must be at a minimum so that combat firing deadlines can be met. Repair parts must be carried to replace defective components. Since only a limited amount of spares can be on hand, the checkout reliability must be high. Once the missile and associated equipment have been checked out, there may be a long wait period while system components are warmed up and turned off several times.

For air defense weapons and long range missiles, this cycling may occur for months and probably years, thus emphasizing the fact that these components must have a long life even if the missile is a "one shot" weapon.

Meeting a firing time also depends on the maintenance of complex electronic and mechanical equipment. This involves both training problems and a built-in system of maintenance. This perhaps can best be met by module packaging with a means for quickly isolating and replacing a defective unit. Maintenance support through various echelons of maintenance must assure field commanders that the firing organization will get parts and repairs for major items of equipment in an expedited fashion.

The key to the reliability of the military operators is a set of valid, troop-tested operating procedures. The commander hopes there will be no deviations from these procedures. However, the continuous equipment changes and modifications to a system after it is put into operational use makes this impossible. The responsibility for getting changes through to the field begins with the developing agency and extends down through the military channels to the operator.

If the missile system cannot detonate the warhead at an effective distance from the target at the proper time, then the tactical reliability is zero for that mission just as surely as if the target were missed by an excessive distance. For military training and contractor test firings, this time factor must be established and an unsuccessful trial charged against the system when it fails to meet the required time. Thus, a missile may eventually be fired successfully although previously charged with several unsuccessful trials because it failed to meet specified times.

Using the same ballistic missile system as in the previous example with a 30-minute time bracket specified as a trial, the three reliabilities might result as shown in the table above. Note that this missile system failed to make the firing times in trials 1, 6, and 7.

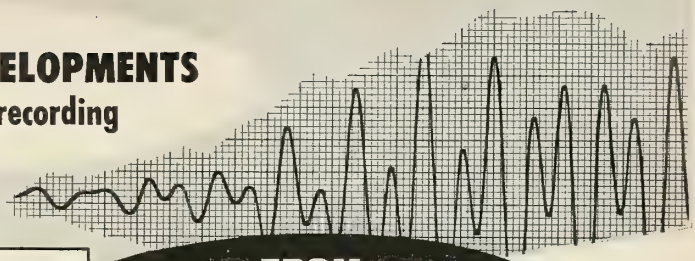
Maintaining and Improving Systems Reliability

Once a missile system has been issued to the field, the commander must be assured that tactical reliability will be maintained and improved. This reliability is a function of the reliability of the critical components of the entire missile system and of the reliability of the military operators. Without such recognition of these critical reliability factors, the finest research and development missile system will never become a successful tactical weapon.

Continued training by mock and live shoots must be emphasized. Units stationed away from one of the few missile ranges in the U.S. seldom get to fire their weapons. When they do fire, they can expand only a few missiles. This makes maintenance of a high level of proficiency very difficult. There is no substitute for actually using a weapon whether it is a rifle, an airplane, or a guided missile.

Consequently, the field commander must turn to mock firings, simulators, and technical assistance teams composed of experienced combat-arms soldiers to accomplish his task. The tactical reliability of a guided missile system and a military crew on the alert for months will indeed be low if an intense program is not followed to keep the state of readiness and training up to a high pitch.

A current analysis of firings must constantly be made to improve the missile system. Military training firings can be utilized for this if telemetry is used. In fact, telemetry should be used if possible for all tactical firings as a feedback of vital information to isolate malfunctions that otherwise never would be known. The developing agency must be on the alert to quickly solve technical problems that appear with tactical use.

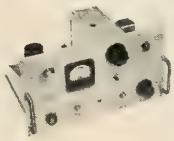


The most efficient means of managing the complex guided missile system from the contractor to the field is centralized technical control under the direction of a single office. Integrating missile channels of supply, maintenance, and information with conventional weapons does not solve the unique problems that have their roots in the firing organization. Remedial action must be immediate if readiness is to be maintained.

Summary

If the symposium participant mentioned earlier had stated that his missile system had detonated the warhead at an effective distance from the target within a specified time for 14 out of 15 trials under simulated military-tactical conditions, the cheers of the audience still would be ringing in his ears. This would have meant that our guided missile program had arrived at the threshold of absolute tactical reliability.

The results of military training and contractor test firings will be much more valid using such concepts of preflight and inflight reliability. In fact, the only way to compare and evaluate the reliability of different missile systems is to use a standard method of determining reliability based on the intended use of the weapon. ★

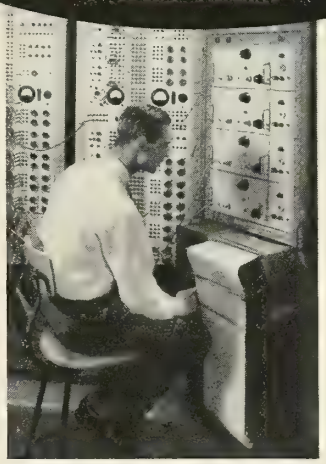


TECHNIQUES and DEVELOPMENTS
in oscillographic recording

FROM
SANBORN

PHASE SENSITIVE DEMODULATOR PREAMPLIFIER PROVIDES A DC VOLTAGE PROPORTIONAL TO AN INPHASE COMPONENT OF AN AC VOLTAGE WITH RESPECT TO A REFERENCE.

THE measurement of the amplitude of an AC voltage component is often necessary in performance studies of servo systems or of suppressed carrier signals over the carrier frequency range from 60 to 10,000 cps. In such cases the demodulator responds to inphase signals and rejects quadrature signals.



A circuit with these characteristics for use in an oscillographic recording system can be seen in the Model 150-1200 Servo Monitor (Demodulator) Preamplifier. It was developed by Sanborn as one of twelve interchangeable, plug-in front ends for "150" Series equipment, to be used with the appropriate Driver Amplifier-Power unit in any channel of a "150" system. Elements comprising the circuit from input to output, include: compensated stepped attenuator and cathode follower input circuit, phase inverter, push-pull mixer and demodulator stages, differential DC output amplifier and low pass filter. In addition, the chassis contains a VTVM to facilitate accurate adjustment of the reference voltage, and an overload indicator which lights a warning lamp when excessive quadrature voltages exist.

Adaptability to a fairly wide variety of applications is accomplished through broad input voltage, reference voltage and frequency ranges. In order, these are 50 mv to 50 v (for full scale 5 cm deflection), 10 v to 125 v; 60 cps to 10kc. Rise time with low frequency plug-in demodulation filter is 0.1 seconds; with high frequency filter, 0.01 seconds. Quadrature rejection is better than 100.1; for carrier frequencies up to 5000 cycles.

Two representative uses of the Servo Monitor Preamplifier are in the design and adjustment of servo systems, and with instruments used in the design, development or adjustment of other apparatus. The first is illustrated by use of the Preamplifier and associated equipment in the recording of the output shaft amplitude and driving frequency of an AC positional servo; the second by recordings made with a similar setup of the difference between output signals from a gyroscopically-controlled stabilizing device and the "pitch" and "roll" signals generated by a "Scorsby Table" used for testing the device under dynamic conditions.

For a detailed discussion of the principles and design considerations involved in the Servo Monitor Preamplifier, refer to the February, 1955 issue of the Sanborn RIGHT ANGLE, for Dr. Arthur Miller's article on "Measurements with the Servo Monitor Preamplifier."

Technical literature and engineering assistance on specific problems are always available from our engineering department.

BASIC FACTORS IN SELECTING OSCILLOGRAPHIC RECORDING EQUIPMENT

WHEN considering any oscillographic system or equipment for your application, three useful "yardsticks" to apply are (1) the recording method, (2) equipment adaptability, and (3) variety of equipment available. Here are the answers to the three, as they apply to Sanborn systems. In the record, rectangular coordinates accurately correlate multiple traces, simplify interpretation and eliminate errors. Permanent traces, produced by a hot ribbon stylus without ink, provide sharp peaks and notches, and clearly reveal all signal changes. One percent linearity results from current feedback driver amplifiers and high torque galvanometers of new design; maximum error is ¼ mm in middle 4 cm of chart, ½ mm across entire chart. From the standpoints of "adaptability" and "variety", Sanborn "150" equipment offers the versatility of 13 different plug-in front ends for any basic system . . . the choice of one- to eight-channel systems . . . the variety of nine chart speeds, timing and coding controls, console or individual unit packaging . . . availability of equipment as either complete systems or individual amplifier or recorder units.

The purpose of the foregoing information is to better acquaint industry with typical oscillographic recording problems and their answers, design considerations in Sanborn equipment, and basic data on what Sanborn makes and how it is being used.

Million - to - One Shot

Reliability Engineering—A New Science to Cut Missile Misses to One-in-Twenty

By William Shepard West
The Martin Company

TO THE ARMED services the proof of a guided missile is in its reliability. A missile is a brilliant weapon, but only when it proceeds to target upon receipt of the first command to launch. There is no second chance.

Military insistence on bug-free missiles finds emphatic expression in a contractual clause that quality control experts soon learn by heart. The clause commits the manufacturer to a reliability standard of, say, 95 per cent. His acceptance is a flat guarantee that when 100 of his missiles are fired, fewer than five will turn out to be duds. The remaining 95 must impact in the target area.

The 95 per cent standard is such a large order that odds of a million to one have been quoted against its achievement. The reliability engineer faces an engineering frontier newly born of military necessity. Outsiders have only a loose understanding of what he is up against. An attempt is made here to explain the reliability engineer's job and to suggest the magnitude of his responsibility.

Most of us started thinking of associated reliability concepts before we were in high school, linking them with dependability. The old college football team was reliable; it could always be counted on to "hold that line." Our first car was reliable; we knew it always would start by the time it had coasted down the hill. Our dog is reliable; she always barks when someone rings the doorbell.

Numbers and Reliability

Let us consider the dog and the doorbell through 10 days in terms of the simplest mathematics associated with reliability. Assume the doorbell is operated 10 times each day for a total of 100 operations. If the dog barks only when the bell operates, we would expect her to bark 100 times in this period. Let us assume that once each day she happens to be asleep when the bell rings, and when she sleeps she doesn't bark. The probability that she will bark when the bell rings, therefore, is 9 out of 10 each day, or 90 per cent of the time.

Suppose that we have five such dogs, each sleeping at random times, and that the doorbell also is operated on a random basis. What is the likelihood that all of the dogs would bark each time the bell rings? Only 60 per cent of the time, by the same simple probability—0.9 x 0.9 x 0.9 x 0.9 x 0.9=0.59. We have assumed that since the dogs do not hear the doorbell when they sleep, they will not hear the other dogs barking.

Briefly restated for the dog-doorbell situation, the problem area is this: a system employing only five items, each of which is 90 per cent reliable, will produce an over-all system reliability of only 60 per cent.

Extending this elementary concept gives rise to some surprising numbers. Consider a hypothetical missile system that has an electronic transmitter, command giver, and a missile—three subdivisions. The transmitter comprises at least a hundred items—wires, resistors, capacitors, tubes, soldered connections. Now if each of these hundred items is 99 per cent reliable, we figure that the over-all reliability of the set is $(0.99)^{100}$, or about 36.3 per cent.

Now it is common knowledge that radios are more than 36 per cent reliable. So the inference is plain that each component in your radio, operating in the environmental condition of your home, with circuits and components of conservative design, performs at a reliability rate higher than 99 per cent. The more highly powered transmitter, with its hundred or more items, works under a greater handicap than does the home set, making achievement of 99 per cent reliability of components somewhat more of a problem.

Environment and Design Objective

The minimum environmental conditions that virtually all systems must be able to withstand are set forth indirectly in the test procedures of military specifications, which imply temperatures from -65 to 160°F, altitudes from sea level to 50,000 feet,

various conditions of vibration, shock and acceleration, etc. The detail specification and the tactical use of weapon systems often exceed the requirements.

Accordingly, the demand on components is vastly more rigorous in tactical use than under typical laboratory or home conditions. Something that works well on a living room table may be inadequate in the deep freeze.

Another difference is the requirement for small size and light weight—a must in military missile applications, but sometimes a sign of cheapness in the home radio. In sum, the rigors of tactical weapon system environments obviously do nothing to encourage the highly dependable operation that the design objectives demand.

More Wood for the Fire

Referring back to the hypothetical missile system, we see that if the transmitter has 100 components, each of which is 99 per cent reliable, the transmitter is about 40 per cent reliable. No doubt, the other two subdivisions—the command giver and the missile itself—are each equally reliable. Our system then has little value because it is (0.40 x 0.40 x 0.40) per cent, or 6.4 per cent reliable, which is virtually useless. What can we do here?

For one thing, we could make each component more reliable. But is our analysis correct? Will the failure of any one component cause the missile to miss the target? There is ample evidence that it will. No item may fail during its intended tactical life.

How about increasing the reliability of the components from the 99 per cent figures we arbitrarily selected until all components and workmanship are 100 per cent reliable? Excellent for missile system reliability, but an impossible assignment. Why this will never happen is discussed by Marcus A. Acheson's "Electron Tube Life and Reliability." Pertinent extracts follow: ". . . if we remove all potential defectives in a lot, we will have removed the entire lot, whether it be a lot of tubes, a lot of people, or the pyramids of Egypt. Nothing lasts forever, and everything existing is a potential defective—we can only discover a rate at which this probability occurs, and lay our bets accordingly on the living population."

If you still demand 100 per cent, try to get an automobile with a guarantee that it will be 100 per cent reliable for its intended life. The writer, actively assisted by a skilled procurement organization, has experienced difficulty getting some component vendors to guarantee that their product will be 97

per cent reliable. Nevertheless, complex missile systems still must live up to an over-all reliability of at least 95 per cent. Our standard of reliability for each vital component and assembly, therefore, must exceed 99 per cent. The problem is familiar to missile manufacturers everywhere.

Financial policy makers might turn to reliability control as a means of reducing the staggering maintenance costs as well as insuring better field systems. Should the cost of developing and manufacturing a weapon system be doubled or tripled thereby, there would still be a net saving.

Framing the Issue

With statistics you can line up a million-to-one case against the probability of 95 per cent missile reliability. Even so, the missile builder has accepted the challenge.

The engineers at Martin have been conscious of the problem of aircraft reliability through the years, but the yardsticks used for aircraft reliability do not apply directly to missile systems. In fact, missile requiremenets are so exacting and their ramifications so diverse that Martin has established teams of experienced technical personnel to work solely for missile reliability wherever it is at stake. In practice, they move in to monitor every step from drafting board to target, including the design, test, production, and operational phases. Working with mathematics, testing methods, and design techniques, they integrate the requisite reliability control into the original engineering releases. Follow-up studies lead to recommendations for corrective measures in all phases affecting the missile system.

The total reliability cost for a typical Martin missile system amounts to roughly $3-million yearly. This figure includes expenditures for testing components, systems and equipment both in the laboratory and on the firing range. Roughly five percent of the engineering man-hours in this project go directly into the reliability effort. This compares to zero hours and zero dollars a few years ago before reliability became a missile problem.

In order to assure optimum results at minimum cost, it has been necessary to formalize the position of reliability engineering in the company's research, development and production structure. An article detailing how this has been done is planned for a later issue of m/r. ★

Honeywell Aero's MIG (Miniature Integrating Gyroscope). Weight: 0.5 lbs. Size: 1.75 inches in diameter. Performance: equal to gyroscopes 3 times larger. Just one of more than 70 new Honeywell Aero products put into production during the past year.

RESEARCH, DESIGN AND DEVELOPMENT ENGINEERS

WHAT WILL YOU THINK OF NEXT?

If it's in aeronautical controls, there are exciting opportunities for you at Honeywell. Honeywell Aero's outstanding development programs now in progress offer exceptional opportunities for research, design and development engineers in the following fields:

INERTIAL GUIDANCE • DIGITAL COMPUTERS • FLIGHT CONTROL SYSTEMS • LIQUID MEASUREMENT SYSTEMS • VERTICAL AND RATE GYROS • STABILIZED PLATFORMS • INLET AREA CONTROLS • JET ENGINE CONTROLS.

At Honeywell, you'll work with your own design team which includes a technician, a model maker, an evaluation engineer and a draftsman. You'll guide your own project from start to finish, get quick recognition and advancement.

You start with a first rate salary and because Honeywell rewards talent as well as experience, increases are based primarily on merit. There's a liberal program of extra benefits, too.

Positions are now open in Minneapolis, Minnesota, city of lakes and parks, which offers exceptional cultural, recreational and educational advantages for your whole family.

Production Engineers. There are also outstanding opportunities for production engineers in the above fields.

WRITE TODAY!

If you are interested in a career at Honeywell, call collect or send your résumé to Bruce D. Wood, Technical Director, Dept. TA19A Aeronautical Division, 1433 Stinson Boulevard, N. E., Minneapolis 13, Minnesota.

what's on your mind?

If it has to do with ballistic missiles, you know you're an ME who's both wanted and needed. But the big question: Where will you be happiest? We're convinced the answer is Firestone, where ideas are king, and where a creative climate encourages idea development.

At Firestone, men with leadership on their minds have pioneered in research, development and manufacture for 57 years. Currently, they're carrying forward the vital "Corporal" program for the Army. Perhaps more exciting, our facilities in both Los Angeles and Monterey are blazing new trails toward history-making goals.

Right now, we need more ME's with minds headed in these directions:

Structures Airframe
Dynamics
Stress Analysis
Materials & Process
Hydraulics
Propulsion System Design

A man at Firestone has a mind to discuss a happy future for you. Write him for a meeting of the minds.

ADVANCED PROPULSION SYSTEMS and EQUIPMENT from a new subsidiary of CURTISS-WRIGHT

The successful development of aircraft and missiles to guard America's security demands the highest order of creative thinking plus a finely-tuned sense of responsibility. A unique blending of these essential qualities with the will and facilities for accomplishment enables Propulsion Research Corporation to solve propulsion problems created by fantastic speeds and altitudes.

Whether developing advanced propulsion systems or the smallest possible axial blower, PRC engineers and scientists work in teams in an intellectually stimulating environment. Projects receive the benefit of impressive resources in research, analysis, design, prototype fabrication and test, and manufacture.

Current programs include engineering, research and development in the turbo machinery and related fields, and development and production of aircraft accessories. Underway are projects in specialized centrifugal and axial flow blower fans, turbo pumps, turbines, fluid pumps, valves, auxiliary power units and cabin conditioning units.

In solving critical technical problems of precision components for aircraft and missiles, PRC is pacing America's progress in the air . . . and into space!

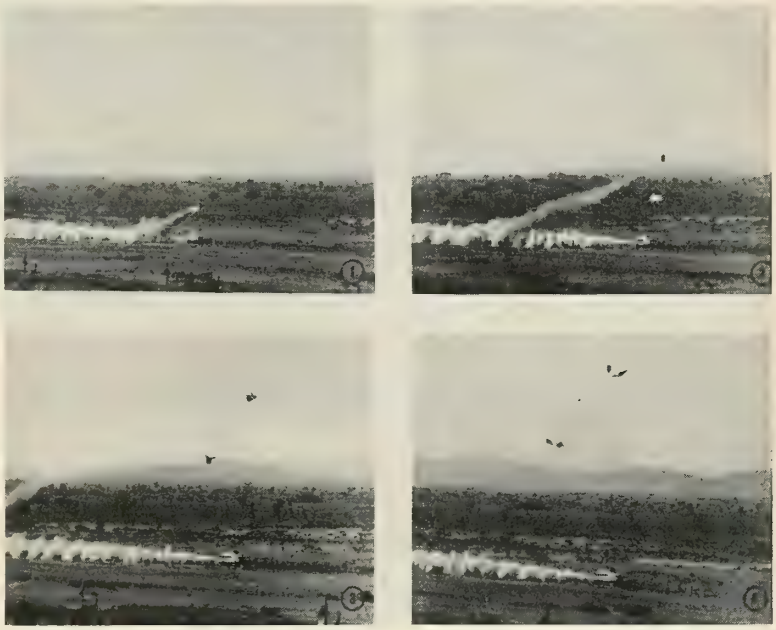
Cold Facts on a Hot Seat . . .

Rocket Sleds Help Supersonic Bailout Design

By Norman Baker
Boeing Aircraft Company

Thirteen major aircraft companies now are working cooperatively on an ejection seat development program. The objectives of this program will be to develop a standard upward ejection seat that will be compatible to the new supersonic jet fighter-type aircraft. The Industry Crew Escape Systems Committee (ICESC) was set up to coordinate overall program activities.



The ARDC has assigned Convair Division of General Dynamics Corp. to coordinate the ejection seat development program. Convair, in this capacity, has subcontracted portions of the development to other companies.

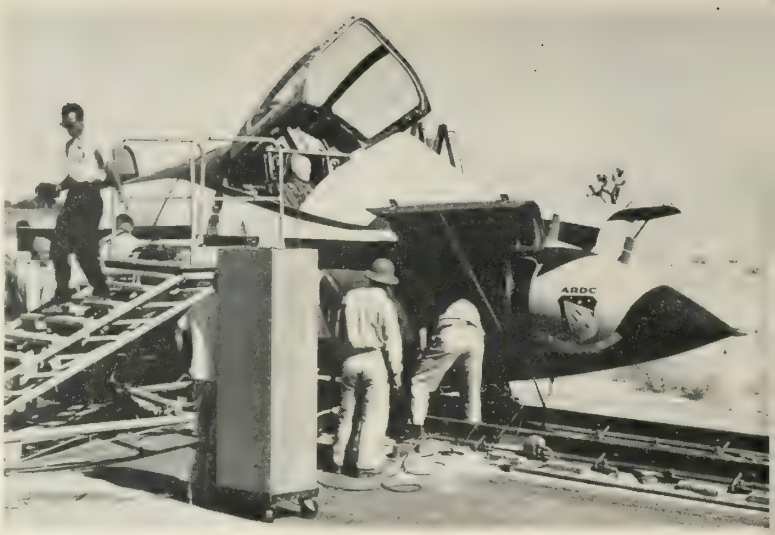
The most recent and outstanding ejection accomplishment of this program has been the development of the RESCU Mark I ejection seat (Rocket Ejection Seat Catapult Upward). RESCU Mark I seat is produced by Talco Engineering Co., Inc., Hamden, Conn. It combines a normal cartridge catapult with rocket propulsion.

RESCU Mark I operates on a two-step principle. The first step in the ejection sequence ignites a ¼ lb charge which propels the pilot's seat vertically. This phase of the operation operates in piston fashion similar to the standard M3 telescoping tube seat catapult. The M3 ejection system propels the pilot upwards, clear of the plane, where he is subjected to the force of the windblast. The tremendous deceleration due to the windblast is the contributing factor for reducing the pilot's chance for survival. The rocket propulsion unit on the RESCU Mark I fires as soon as the seat is clear of the cockpit. A 5-lb. propellant grain fired through a canted nozzle carries the pilot further from the aircraft.

Thrust of the rocket is in a line through the center of gravity of the seat-pilot combination. This adds a forward force vector to the ejection line of travel imparting a resultant forward force which tends to offset the force of the windblast. The thrust through the center of gravity of the seat-pilot unit creates dampening forces which reduce tumbling.

Convair Engineering Test Laboratory engineers and Air Force technicians recently made comparison tests

High-speed sequence camera records ejection of two dummies from Convair TF-102A rocket sled at Edwards AFB in California. 1) RESCU Mark I seat, trailing smoke from rocket clears cockpit. 2) M3 cartridge seat (arrow) is ejected as RESCU Mark I rocket burns out. 3) Rocket seat follows trajectory well above M3 seat. 4) Dummies separate from the seats. Elapsed time: less than one second. 5) Parachutes on dummies start to open. 6) Parachute of RESCU Mark I has opened fully. 7) Rocket propelled dummy starts to assume vertical attitude while M3 propelled dummy is still horizontal. Seat is upper right. 8) RESCU Mark I dummy (upper) making safe normal descent .M3 dummy is still in an unstable attitude.



of the M3 and RESCU Mark I ejection systems. Two instrumented anthropomorphic dummies were mounted in seats on a TF-102A nose section rocket sled at Edwards AFB test track. The side-by-side seating of the TF-102A trainer cockpit afforded the engineers an excellent opportunity for comparing the RESCU Mark I and the M3 ejection systems.

One seat was ejected by the RESCU Mark I unit, while the other seat was ejected by the M3-type cartridge catapult. Recent tests at Edwards, first of a long-range development program, were run at Mach .3 and Mach .73. In these initial tests the rocket propelled seat followed a much higher trajectory and the parachute attached to the dummy blossomed more fully than that of the dummy ejected by the M3. This resulted in a more stable, normal descent by the RESCU Mark 1 propelled dummy.

In the first test at Mach .3, the rocket seat propelled its dummy 124 feet above the ground. During this time M3 ejected seat had hoisted its dummy to a height of only 55 feet. During the second test at Mach .73, the rocket seat ejected the dummy to a height of 60 feet above the TF-102A's vertical fin. The seat ejected by the RESCU Mark I system experienced a smooth acceleration, instead of the explosive jolt produced by the M3 cartridge. This reduces the hazard of spinal compression which could be experienced during the ejection by the M3.

The entire sequence of ejection was recorded during these test runs by still, high-speed-sequence and motion picture cameras. Two telemeter transmitters were located on the sled and one in one of the dummies for further correlation of test information.

John G. Kalogeris, Convair engineer in charge of tests at Edwards, states that the new rocket seat "for the first time gives the pilot a good chance of ejecting safely from ground level in case of emergency."

Preparing for takeoff. Air Force and Convair engineers ready TF-102 sled for seat ejection test.

Electrofilm

HEATING ELEMENTS

ENGINEERED TO FIT YOUR DESIGN

SPRAYED-ON • FILM TYPE

for contour shapes

LIGHT: Weight 1/10 lb. per sq. ft.; only .012" thick

STRONG: Withstands severe thermal shock

THIN: Near zero thermal inertia. Reduces power requirements due to maximum heat transfer properties

RESISTANT: Resists electrolytes, water, oils, abrasion and weather

WIDE RANGE: Operates any voltage; 6 volts D.C. to 220 volts A.C.

New! sub-miniature ACERELAY* features outstanding Reliability

actual size

Typical Specifications

Contacts — double pole double throw bifurcated, break before make or make before break contacts

Contact Rating — 3 amp resistance @ 115V AC or 28V DC

Coil Resistance — to 10,000 ohms

Vibration — 5-2000 CPS at 20G

Shock — 50G

Life — minimum of 500,000 operations

Meets MIL-R-5757C

The above are standard. Modifications available.

Weighing less than ¾ of an ounce and no larger than a 3¢ stamp, the new ACERELAY (patent applied for) incorporates design advances which assure greatest reliability under the most severe conditions of shock, vibration, and acceleration.

The 201 Series ACERELAYS are ideal for missiles and rockets, radar systems, computers, ground and airborne equipment, and wherever ultra-compact size together with positive reliability are demanded. Prototypes delivered in 2 weeks . . . production quantities given expedited service.

Call or write today for complete details.

The Deadly DART Strikes Home!

The fast and powerful Dart is a rocket propelled surface-to-surface missile designed for Army Ordnance by Aerophysics Development Corporation, a subsidiary of Curtiss-Wright.

The smokeless – solid propellant rocket motor was developed by Grand Central under sub-contracts from Aerophysics Development Corporation and Army Ordnance. The deadly Dart is one more application of dependable solid propellant rocket power by Grand Central.

The Dart is but one of many interesting rocket projects currently under way at Grand Central. We invite qualified applicants to join this congenial and highly-skilled team of scientists.

Please direct professional applications to the Personnel Manager

Grand Central Rocket Co.

REDLANDS, CALIFORNIA

GRAND CENTRAL ROCKET CO. REDLANDS CALIFORNIA

Tailoring Molecules *for* Rockets

by Dr. David Z. Lippmann

A member of the Chemistry Department Staff at Reaction Motors, Inc., Dr. Lippmann specializes in combustion processes and theoretical analysis. He received his B. S. and M. A. in Chemistry at the University of Texas and his Ph. D. in Physical Chemistry at the University of California at Berkeley. He has been with RMI for three years.

The practical future of rocket power depends upon a great many factors—not the least of which is the solution of the problems facing the rocket propellant chemist. The ultimate rocket chemicals—whether nuclear, solid, liquid (mono- or bi-propellant), hybrid or the new "exotic" chemicals —must lie within the limited parameters of certain rigid requirements. This discussion deals with some of those basic considerations which influence the chemist's search for improved high energy rocket propellants.

The conventional rocket motor is a heat engine which converts the chemical energy of propellants into heat and the heat into kinetic energy. Propellants react in the combustion chamber of the rocket motor, releasing heat and forming gaseous products, which expand through a nozzle; the expansion converts part of their heat energy into kinetic energy. The gases, now moving at high velocity, are exhausted to the rear, and by the reaction principle they impart a forward force, measured in pounds of thrust, to the motor.

The thrust exerted by a rocket motor is proportional to the exhaust velocity of the reaction products. To produce a high exhaust velocity, the reaction of the propellants must yield a large quantity of heat per unit mass and this heat must be converted into kinetic energy efficiently.

The heat produced is the difference between the heat of formation of the propellants and the heat of formation of the reaction products; so the propellants should have large positive heats of formation and give products with large negative heats of formation. Because of the requirement for large heat of reaction per unit mass (not per mole), only the lightest elements are used in propellants. The most desirable elements are hydrogen, lithium, beryllium, boron, carbon, nitrogen, oxygen, fluorine, magnesium, aluminum and silicon; elements heavier than chlorine are rarely used. The heats of formation of propellants are maximized by incorporating high energy groups such as $-C\equiv C-$, $>N-N<$ and $-OO-$ into the propellant molecules.

The efficiency of conversion of heat into kinetic energy is inversely proportional to the mean molecular weight of the reaction products. Therefore propellants are designed to give light products, such as H_2, H_2O and CO.

These three requirements, i.e., that the propellants have large positive heats of formation, that the products of reaction have large negative heats of formation, and that the products have low molecular weights, cannot all be optimized simultaneously. A good propellant must have an optimum balance among them. In addition, a propellant should have other desirable properties, such as stability and high density.

The chemistry laboratories at RMI, in support of the applied research, development and production of advanced rocket power systems, are staffed with a team of specialists, highly qualified in many phases of chemistry and chemical engineering. This team is constantly working toward the achievement of this optimum balance of properties in their search for advanced rocket propellants. The well-rounded program of research, analysis and evaluation which contributes to this goal includes such typical activities as mathematical analysis, theoretical chemistry, propellant formulation, combustion chemistry, organic and inorganic synthesis, physical properties and analysis, with special sections devoted to solid and liquid propellant research.

Rockets for Black Gold

Proving that what goes up must come down, Grand Central Rocket Co. has developed a rocket for ramming new life into old and tired oil wells. Using a specially designed, controlled burning rocket motor sealed in the bottom of the well to build up pressure that exhausts through blowout plugs, oilwell engineers have exerted downward pressures equivalent to 5000 hydraulic horsepower in a single surge. In some cases the resulting soil fractures have enabled pumping rates to be increased 300 per cent. In the drawing, the igniter is at the top; rocket fuel in the middle; and firing nozzle at the bottom. The entire unit is only seven-and-a-half feet long and is dropped readily down the well casing. This is the first commercial use of one of Grand Central's solid rockets. The company also has the third stage Vanguard contract.

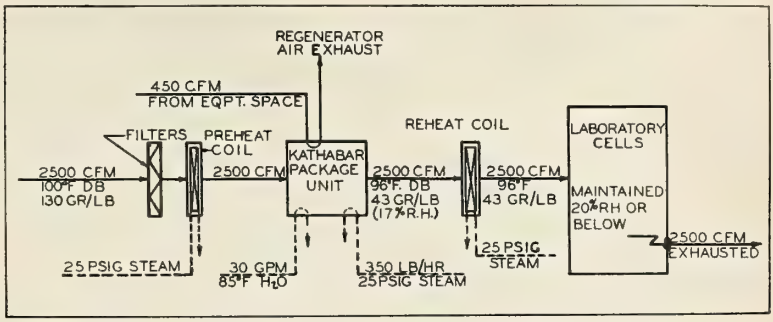
Humidity Control for Rocket Propellants

Working under a United States Air Force contract, Phillips Petroleum Company is utilizing related petroleum and chemical technology, their research knowledge and experience to develop new solid rocket fuels. These propellants are prepared and tested in small rocket motors at Bartlesville, Okla.

A chemical-type humidity conditioning system which serves this laboratory plays a vital role in the success of this program. Some of the chemicals used to compound these propellants are extremely hygroscopic. Both the physical and ballistic properties of the propellants are dependent on moisture present during processing. Tests on successive charges from a single batch could vary widely if change in moisture content occurred.

Solid propellant JATO units have been used for several years but have been made of expensive ingredients having limited availability. Phillips researchers are striving to develop a solid, less expensive propellant made of ingredients readily available in this country in large commercial quantities.

Several have been developed and are now being tested. Relatively simple devices, they ignite and burn in bottles or motors which can be made of inexpensive steel. Burning evenly and rapidly, the resulting gases travel through the nozzle at tremendous speeds.



In the ideal JATO rocket there is little flash or smoke and the gases are not toxic or corrosive. Once compounded and sealed in the motor, it should not vary in physical or firing properties even under tropic or arctic storage conditions.

Need for Humidity Control

Much of the solid propellant fuel development is "classified" for security reasons. Actual components cannot be named. It can be said, however, that the principal ingredients are a chemical oxidizer mixed with a binding agent which serves as the fuel.

Some of the chemicals used to form these charges are hygroscopic and are dried before use. To protect their physical properties during compounding and to insure accurate ballistic results from an entire batch, charges must be protected from moisture remain.

Initially a dessicant system was installed to maintain conditions in the laboratory cells at from 25 to 30 per cent relative humidity. In this humidity range the moisture in the air and that in the chemicals were barely at equilibrium. This dehumidifying equipment proved unsuccessful as it could not handle the sudden, high moisture loads placed upon it.

Schematic layout of Phillips Petroleum Co.'s humidity control system.

Many of the test cells are regularly hosed down to cleanse the surfaces of accumulated propellant dust particles. After various other systems were investigated, a very successful chemical-type dehumidification system was installed.

These units, two of which are used in the laboratory, are Kathabar Humidity Conditioners, manufactured by Surface Combustion Corporation, Toledo, Ohio.

Air Conditioning System

In Figure above is shown a schematic flow diagram of one of the Kathabar systems. All fresh air is used to avoid the accumulation of rocket fuel dust in filters and ductwork.

The 2500 cfm of air is shown entering the system at 100°F dry bulb and 130 grains of moisture per pound, maximum summer design conditions. This air passes through filters and enters the unit's air washer chamber. Both the preheat coil and the afterheat coil are for winter operation.

This system uses a liquid absorbent called Kathene. Its moisture absorbing capacity is a function of its concentration and temperature.

Thus, the Kathene solution at a set concentration is cooled in the air washer chamber to the temperature predetermined for proper dehumidification. Automatic regeneration in a separate chamber is accomplished by heating the solution with steam.

CHIEF MECHANICAL ENGINEER

. . . needed for challenging work in the growing field of upper atmosphere research by expanding pioneer in plastic stratosphere balloons.
You will do work on the design of space capsules, their instrumentation, and associated equipment.

If you have a background in modern aircraft structure design, mechanical, or aeronautical experience, please send your resume in confidence. Salary is open.

hofman LIQUID OXYGEN QUICK COUPLINGS

POSITIVE SEAL — NO GASKETS

Hofman Quick Couplings are designed to utilize mechanical CAM ACTION giving metal to metal medium pressure contact in place of gaskets for a POSITIVE seal while requiring only ¼ turn to open or close. Fabricated from high quality bronze, these units will give long, trouble-free life. Hofman Quick Couplings are available in 1", 1½", 2", 2½", 3" and 4" sizes. Armored transfer hoses with couplings installed can also be furnished.

Send for our new 16 page catalog LOW TEMPERATURE APPARATUS

hofman Laboratories, Inc., Newark, N. J.

West Coast Agent: BLAIR-MARTIN CO., INC., 1010 Fair Oaks, So. Pasadena, Calif.

In the air washer chamber the air stream contacts a flood of the Kathene solution as both pass over the extended surface cooling coils. The coolant in these coils both cools the absorbent solution to the right temperature for dehumidification and cools the air. The air is dehumidified and goes on to the distribution duct system. The solution falls into a sump from which it is pumped back to the top of the air washer chamber for additional dehumidification passes. A small quantity of solution is also pumped to spray heads in the regenerator.

When the solution becomes diluted, steam is passed through the coil in the regenerator. This heats the solution, forcing it to give up the absorbed moisture. The solution falls into the sump once more and the released moisture is entrained by a scavenger air stream, 450 cfm as indicated on the drawing, and vented outside. Regeneration is completely automatic.

After the dehumidification pass, the air, at 96°F, 46 gr/lb (17% RH) is ducted to each test cell. The cells are constructed of double reinforced concrete, one foot thick. They are baffled to contain shrapnel in case of an explosion and have blow-out panels to allow the explosion force and gases to escape.

Maximum utility requirements of this system are 30 g.p.m. of 85°F water and 350 lb/hr of 25 psig steam. The unit has a wide range of turndown. When outside conditions are not maximum design, it will deliver air at 17 percent RH and much lower, still using only 85°F water. Less steam is also required when outside conditions are below 100° F and 130 gr/lb. The second unit, 1350 cfm capacity is now placed on standby. Connected to the same duct system it can be utilized if increased activities should overload the first unit, or when planned expansion is authorized in the future. All duct work in the system is interconnected to allow the entire 2500 cfm to be directed to one, two or any combination of test cells if needed.

In the southwest, electric power is more expensive than any other energy source. Since this unit has only a ¾ h.p. pump motor and a 1 h.p regenerator air fan, operating costs compared to other systems are much less. As these are the only moving parts of the system, only routine maintenance is necessary.

Another factor in favor of this system is that there is no "carryover" of absorbent solution in the leaving air stream. Carryover of any kind would impair the accurate compounding and testing of rocket charges. ★

"NIGHT CHESS" a painting by Simpson-Middleman, a doubly gifted team of artists with a scientist's penetrating insight. They portray here "a chess-like game played in a segment of space on a skewed board with pieces of uncertain value against an unknown antagonist. The next move is unforeseen—it will come out of the dark—it will be history's most fateful gambit."

High stakes are yours to win at Boeing

Your future comes quickly at Boeing . . . for the future is Boeing's business. There is no reverence here for "limits"—creative engineers are exploring exciting pathways into the unknown.

Here, the jet age has already begun in air travel. America's first jet liner, the giant Boeing 707, has been test flying for over 2 years.

Because Boeing is already looking beyond this and other "tomorrows," still searching more distant horizons, we need you.

We welcome all types of engineers and scientists and advanced mathematicians who enjoy the excitement of being far ahead in the vaster vistas of supersonic flight, of electronic guidance, in virtually every field associated with flight.

It is a stimulating experience. And in this sympathetic climate, you'll find very quickly that "you belong . . . at Boeing."

Drop a note now to John C. Sanders, Engineering Personnel Administrator, Boeing Airplane Company, Department R-61, Seattle 24, Washington.

BOEING

HOW FAR IS A Stone's Throw?"

Pretty far, when the 'stone' is the Army's Redstone Missile, which is the responsibility of the Army Ballistic Missile Agency at Redstone Arsenal in Alabama. While range figures are classified, you can be sure the Redstone can carry its warhead a long way.

Servomechanisms, Inc. designed and developed the Redstone's Thrust Controller system, which operates to maintain constant pressure in the Rocket Thrust Chamber. As an indication of its accuracy and reliability, the system controlled pressures to within 1% of the CHAMBER PRESSURE in hundreds of hot firings.

This is an excellent example of how Servomechanisms, Inc. has utilized the experience, acquired through years of developing accurate and reliable sub-systems for high performance jet aircraft, to make a substantial contribution to the guided missile field. Many other developments in this field are now in progress.

Propulsion Notes

By Alfred J. Zaehringer

California Research Corp. has patented a rocket fuel (acyclic mercaptans with 1-5 carbon atoms) for hypergolic use with nitric acid. Mixed mercaptans obtained from naptha cracking process can be used. The fuel can also be blended with up to 50% volume of hydrocarbon fuels. Small additions (2-to-20%) of nitric oxide, sulfuric acid, or $NOHSO_4$ to the oxidizer reduces ignition delay. A 1:3 (volume) mixture of ethyl mercaptan and nitric acid (with 15% sulfuric) gave an ignition delay of 10 milliseconds at —40° F.

Add to the growing list of "Zip" investigators. Diborane flame studies have been reported by Battelle Memorial Institute and the Royal Aircraft Establishment. In stability studies Battelle ran into unusual flame holding effects and other abnormal behavior, apparently caused by the deposition of large amounts of B_2O_3 slag in flameholders.

The French have devised a continuous method for producing isopropyl nitrate. The direct interaction of nitric acid and isopropyl alcohol gives a 78% yield based on the original amount of alcohol.

Eugen Saenger of the Research Institute for Physics of Jet Propulsion (Stuttgart, Germany) hypothesizes that "photonic gas," a type of radiation, may govern the mechanism of propellant combustion and the detonation of solid and liquid explosives.

British Imperial Chemical Industries has come up with a new solid propellant for low-pressure or rocket propulsion. Oxidizer is guanidine nitrate (88.75%). Polymitrophenols or polynitrosophenols (10-35%) are used to "sensitize" the thermal decomposition of the oxidizer. Catalyst is vanadium pentoxide (0.2-1%). Other additives are asbestos fibers (0.5%) and potassium nitrate (0.25%). Apparently the propellant is formed into grains by compression.

General Electric has in operation a $2 million Propellant Development Lab. at Evendale, Ohio for exploring the combustion of new fuels "with heavier hydrocarbons than JP fuel."

Hydrazine for propellant use is still small. Present cost is $2-3/lb. Present producers are Olin Mathieson and Fairmount Chemical. Stanford Research Institute is now working on a non-aqueous electrochemical process which could bring costs way down.

Next producer of UDMH may be Metalectro (Laurel, Md.) recently acquired by National Distillers Products Corp. Present producers are Commercial Solvents, Food Machinery, and Olin Mathieson.

The Navy has awarded a $38 million contract to Callery Chemical to build a high energy chemical fuel plant. Probable production: pentaborane for chemically fueled bombers.

Ammonium picrate for solid propellants now seems dead. The last government production plant at Little Rock, Ark. is to be sold.

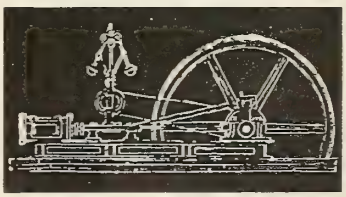
Look to Canadian Industries, Ltd. to enter the solid propellant field. Location may be at its Nobel Works in Ontario, Beloeil Quebec, or Edmonton, Alberta.

Production of hydrogen peroxide is now near 45 million lbs./yr. Latest entries in the production field are Solvay Process at Syracuse, N. Y., Shell Chemical at Norco, La., and Columbia-Southern at Barberton, Ohio. Estimates are that 30-50% of total production goes into military use.

"HOT NEWS"
for Rocket Engineers!

Woven Material Resists Temperatures up to

2000°



RUSCO has developed a technique of weaving Ceramic fibre into an extremely flexible product particularly adaptable to Rocket and Missile parts insulation.

It can be provided in a wide range of shapes . . . tapes, sleeves, tubes . . . in fact any size or shape to meet your specification.

In Washington for Defense Department's recent missile auxiliary power unit symposium were Paul Ricks (facing away), AiResearch Project Engineer and ex-Peenemunde researchers Rudolph H. Reichel and Fred R. Kunze, both with Bell Aircraft.

T. I. Paganelli has been appointed ngr. of the Special Radar Projects Sec- ion, General Electric's Heavy Military Electronic Equipment Dept., which is re- sponsible for development of new elec- ronic systems for ballistic missiles. **E. P. Heinemann** has been named manager- naterials of General Electric's Light Mili- ary Electronic Equipment Dept.

Harrison A. Storms, Jr., succeeds **C. . Hansen** as chief engineer of the Los ngeles Div. of North American Aviation. Mr. Storms was formerly mgr. of research nd development.

J. Raymond Berry, Jr. has been ap- ointed Washington representative for North American's Missile Development nd Rocketdyne divisions.

Former CAA Administrator **Fred Lee** as joined Olin Mathieson Chemical Corp. s asst. to **W. Foster,** executive v.p. in harge of high energy fuel operations.

Dr. Louis F. Doty, recently supervisor f weapons systems planning in General lectric's Nuclear Propulsion Dept., rejoins ircraft Armaments, Inc. as head of the erodynamics Dept.

J. F. Forster, vice president and asst. eneral mgr., Vicker's, Inc., has been ap- ointed executive v.p. in charge of all ickers operations.

Andrew F. Haiduck has been named xecutive v.p. of Lear, Inc., supervising nd coordinating activities of all company ivisions and subsidiaries, as well as as- uming duties of **A. G. Handschumacher,** ice president and director of sales, who as joined another company.

Norman F. Trost, formerly with Gen- ral Motors' Aeroproducts Div., has been ppointed president of Narmco Mfg. Co.

Jesse Zabriskie, division mgr. of Bell ircraft's Guided Missiles Div., announced he appointment of **Tex S. Lines** as his ssistant and **John C. Parkin** as director f engineering.

B. F. Coggan was elected vice presi- ent and manager of Convair-San Diego nd **Charles F. Horne,** vice president and anager of Convair-Pomona.

Robert H. Noorduyn has been ap- ointed Dallas district mgr. for Walter idde & Co.'s Aviation Div.

Walter T. Runiewicz and **William M. unwody** have been named chief com- onents engineer and chief systems en- ineer, respectively, for Clifton Precision roducts Co.

Harold C. Erskine, general mgr. of the castings division, has been named asst. general production mgr. for Aluminum Company of America. He was formerly director of the Aluminum and Magnesium Div. of Business and Defense Services Administration, Dept. of Commerce.

PAGANELLI

Senior AiResearch project engineer C. F. Drexell shows press FALCON power unit.

TROST

Richard A. Maher has been appointed chief engineer of Hoffman Laboratories; **Carlton Wasmansdorff,** vice president, has been assigned to the research and development of new electronic systems and products; **E. Philo Davis** has been named manager of advertising and sales promotion; and **Tom C. Clark** has been appointed director of military sales.

Eugene J. Venaglia will be manager of Sperry Rand Corp's new electronics laboratory at Clearwater, Fla.; **Paul T. Cullen** has been promoted from surface armament sales representative to asst. to the president and general mgr. of Sperry Gyroscope Co. **Charles S. Rockwell** has been named vice president and general mgr. of the Ford Instrument Co. div. of Sperry Rand Corp.

C. E. Pappas was named asst. director of scientific research for Republic Aviation Corp.; **Travers Auburn** has joined the company as chief industrial engineer.

Roland C. Webster and **Rudolf H. Edelston** have joined the Chemistry Div. of Atlantic Research Corp., Alexandria, Va., where Webster will work on the development of rocket-powered seat ejectors and Edelston with the design of rocket components and rocket testing equipment.

Franklyn E. Dailey, Jr., has been appointed mgr. of the applied science section, Research and Advanced Development Dept. of Stromberg-Carlson.

Harry E. Pinkerton has been named president of the International Electronics Corp. (Intec), a joint American-French venture into the field of electronics.

Cliff Anliker was appointed supt. of manufacturing of Robertshaw-Fulton Controls Co.'s Aeronautical Div.

Louis E. Benitez has been promoted to director of customer relations for armaments systems, **Thomas J. Mitchel,** to director of electronic systems, and **Perry Smith** to director of commercial sales, Crosley Div., AVCO Manufacturing Corp.

W. R. Miller has been appointed vice president of Longren Aircraft Corp., in charge of Longren de Mexico.

John S. McCarthy was selected as McDonnell Aircraft Corp.'s Dayton, O. representative to handle military relations and engineering.

R. B. Young has been appointed general mgr. of Aerojet-General Corp.'s liquid rocket plant at Sacramento; **Dr. John V. Atanasoff** has been named resident mgr. of Aerojet's Ordnance Engineering Div. at Frederick, Md.

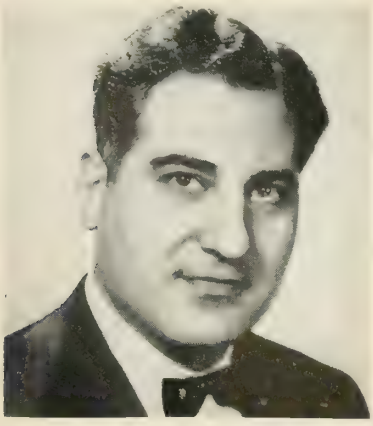
COLE

L. E. Dalton was elected vice president in charge of manufacturing for all divisions of the Kelsey-Hayes Co.

Herman J. Pelkey has been named plant mgr. of the Kellett Aircraft Corp.

Robert A. Cole, supervisor of computation and data processing for Boeing Airplane Co.'s Bomarc project since its inception, has joined Tally Register Corp. as chief engineer.

Dr. James E. Shepherd will direct Sperry Gyroscope's Electronic Tube Div. to be located at Lake Success, N.Y.



A. A. Demetriou is in charge of new office at Huntsville, Ala., to represent Northrop Aircraft and subsidiary, Radioplane Co., at Redstone Arsenal.

Andrew A. Nargizian, a pioneer member of the World War II Manhattan Project, has been appointed assistant to the president of Avion division of ACF Industries to coordinate missiles systems activities at the Avion plants in Paramus, N. J., Alexandria, Va., and Los Angeles.

Carl W. Bollum, Sr., former deputy chief of the Army Ballistic Missile Agency's Washington Office, was named engineering asst. to the general mgr. of Fairchild Guided Missiles Div.

Douglas B. Nickerson has been appointed chief engineer of Hydro-Aire, Inc., replacing **Richard M. Degen,** resigned. **Lt. Gen L. C. Craigie** (USAF, ret.) has resigned as vice president-engineering of Hydro-Aire but will continue to serve as a director and consultant.

Richard L. Bean has been appointed public relations mgr. of Lockheed Aircraft Corp.'s California Div., succeeding **William R. Wilson** who has been assigned as director of market development in Lockheed's expanded aircraft sales organization.

NARGIZIAN

Raymond J. Condon has been appointed vice president in charge of government projects for Minneapolis-Honeywell, with headquarters in Washington, D.C.

Stanley W. Burriss and **John H. Carter** have been named managers of the weapon system organization, Lockheed's Missile Systems Div., at Sunnyvale and Palo Alto, Calif. respectively.

Richard B. Gulliver has been appointed mgr. of industrial relations of the Fairchild Guided Missiles Div., replacing **Lynn G. Walck,** resigned. **John W. Robinson** has been named public relations asst. for Fairchild Engine and Airplane Corp.

Dave N. Peterson, formerly executive advisor to vice pres. **Stan Smithson,** has been named facilities administrator for North American Aviation's Missile Development division. **Norman P. Hays,** retired Air Force colonel and formerly chief of the Armament Laboratory's Strategic Bombing Branch, was appointed asst. to the gen. mgr. of the Autonetics division. **Robert J. Clark** has been named mgr. of North American's new European office in Geneva, Switzerland.

BOLLUM

C. A. Gongwer, co-inventor of the MiniSub, has been appointed to the new Large Solid Propellant Rocket Advisory Committee of the Aerojet-General Corp.

Donald E. Brown has been appointed chief engineer of Consolidated Electrodynamics Corp.'s Glendale div.

Under a new setup at Northrop Aircraft, Inc., **Robert R. Miller,** vice president and gen. mgr. of the present company, becomes corporation vice pres. and gen. mgr. of the Northrop Div., embracing the company's aircraft and missile facilities; **Dr. William F. Ballhaus,** chief engineer of Northrop, was elected vice pres. and chief engineer of the Northrop Div.

Charles E. Arnold has been appointed mgr. of the Avionics Laboratory of Sylvania Electric Products Inc. and **Frederick J. Anderson** is assistant mgr.

Frank M. Viles, Jr., has been named vice pres. in charge of manufacture of semi-conductors of Federal Telephone and Radio Co., a div. of International Tel. and Tel. Corp.

George H. McKaig is the new mgr. of production planning and **James T. Jones** has been named mgr. of production engineering at Hughes Aircraft Co.'s manufacturing div.

FIVE IMMEDIATE OPENINGS FOR DESIGN ENGINEERS

★

Armament Design Engineer. To design, install and test gun, rocket and missile systems. Requires degree in Engineering and either one year armament installation design experience, or three years general design experience.

★

Senior Surfaces Design Engineer. To create production design of wing, tail and control surfaces for missiles and fighter aircraft. Engineering degree and four years design experience.

★

Senior Hydraulics Designer. For development, detail design and test work on complex hydraulic power control systems. Engineering degree and at least four years experience in hydraulic design.

★

Support Equipment Engineer. For a wide range of development assignments including complete airborne photo systems and submarine handling equipment for guided missiles. Engineering degree and at least three years design experience.

★

Designer for Pilot Escape System Requires Engineering degree and at least three years work with pilot escape mechanisms, plus other related practical design experience.

To arrange for a personal interview, or for a prompt, confidential report on these openings, write to:

Mr. J. W. Larson, Asst. Chief Engineer
Dept. MR-2

CHANCE VOUGHT AIRCRAFT
INCORPORATED DALLAS TEXAS

A Vought Vignette

FIRST IN A NEW SERIES

The Aircraft Designer Who Went to Sea . . .

IT WAS A ROUTINE CRUISE for the *Bon Homme Richard*. But for Wayne Burch, it was a memorable climax to months of hard work. Aboard the carrier with the Chance Vought design specialist was the white-lacquered fighter he'd worked on so long.

★

Wayne had joined the Crusader dayfighter project in Preliminary Design, on alighting and arresting gear. He'd transposed his initial drawings into detail design and, later, he'd watched his gear pass jig and aircraft drop tests. At the Navy Test Center, the Crusader's gear absorbed maximum sink speeds and arresting tension, and Burch once more was there.

★

Now, Navy pilots on the *Bon Homme Richard* were taking the Crusader to sea, and Burch was going along. This time his assignment was simply to watch, and this time the Crusader was to be just part of the picture. Vought wanted him to experience carrier life and to see how his new weapon fitted in. For Wayne, whose sea log began and ended with one day's fishing from a 20-foot launch, it promised to be an eye-opening voyage.

For six days the designer shared quarters with Navy fighter pilots and had coffee with maintenance men. He studied aircraft spotting and catapulting, and he learned the sign language of the LSO (Landing Signal Officer). He marveled at the fingersnap timing of the Navy's deck handlers and at the *Bon Homme Richard's* mid-voyage refueling of two bobbing destroyers.

★

Wayne calls it "one of the most enjoyable weeks of my life" . . . and, as other sea-going Vought engineers have discovered, "one of the most profitable, too.

"Now I know the pilot's job, what maintenance wants . . . how really big the operation is.

"It's something you don't get if you stick too close to design.

"I guess you'd call it *perspective*."

At Chance Vought the designer stays in touch with his product . . . Contact begins in development, extends through test and includes, when possible, a study by the designer of the tactical environment in which his weapon will serve.

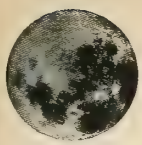
CHANCE VOUGHT AIRCRAFT
INCORPORATED · DALLAS, TEXAS

Eyes that look beneath the sea

SEARCHING the depths of the sea for submarines, mines, to locate wrecks, to aid in navigation, to guide fishermen to a catch—these are some of the accomplishments to date of sonar as developed by Minneapolis-Honeywell.

Original research in sonar is continuing at our marine equipment laboratory in Seattle, and aboard our specially designed research ship, *Neper*.

If you are interested in developmental work in any phase of underwater ordnance, Honeywell's Ordnance Division would welcome your inquiry. They are prepared to put the facilities and talent of our sonar experts to work for you immediately—and to draw upon our pool of 25,000 skilled men and women in research, engineering, design and development, production and field service.



For further information, write to Honeywell Ordnance Division, Dept. MI-3-74, Hopkins, Minnesota.

Missile Miscellany

An old and thinking friend who actually doesn't wish to quarrel with Einstein has a question about a clock at speed that goes slower: "According to Relativity, the clock in motion can be considered at rest, and the clock at rest, in turn, can be considered to be in motion. Doesn't this raise the possibility that when the journey's finally over and the two clocks are back together, each will be slower than the other?"

Relativity also requires the equivalence of gravitic and inertial mass. If so, explain why a gravity pendulum with a bismuth bob gains one beat in 17.432 by another pendulum of exactly the same oscillation length having a zinc bob; and why torsion pendulums act similarly.

And out of Chicago, an industrial designer with some engineering knowhow feels the "blasting off" rocket is about as primitive as a Chinese firecracker, and as close to what a space ship will look like as the ornithopter was to the airplane.

A rocket engineer cloud-walking the recent space-flight symposium figures berrylium liquid propellants may result in a 0.96 mass ratio and a practical two-step moon vehicle . . .and from elsewhere, recent reports of exotic additives to solid propellents. This page also hears of concern over the possibility of radiation damage to rocket fuels at high altitudes . . . And then, there's the AF major who wants to transport ice and water from Jupiter to Venus so as to make the latter inhabitable.

Navy, researching a way to make domesticated algae do a quicker conversion job of CO_2-to-O_2, is bothered by algae who shade their brothers from light source—wonders how to "mix light in" with little fellows. Is this for permanently submerged atomic submarines, or space ships?

This page too has its "authoritative sources", one of whom tells that in exchange for missile knowhow and hardware, Britain will supply U.S. with IRBM bases.

Overheard from a disgruntled radar operator dangling his toes in the blue Pacific: "A Regulus launched from a submarine made it unscathed to target through combined coastal defenses". . . . This page also learned that some one finally thought of podded tanks for extending range of the air-breathers now in service . . . a sound system expert with a 25-year interest in rocket mail reports that Italy last year issued a stamp with a satellite circling the world . . . of Wernher von Braun's products, this comment from a major missile component supplier: "—cast iron products that look like flying washing machines, but practical" . . . a reference to the Pentagon as the puzzle palace from a Navy combat count-downer . . . while lunching, an aerodynamicist after a frustrating morning trying to rationalize Reynolds numbers, laminar flows and transfer heating rates concluded: "What we're trying to do is sphere the cylinder". . . . with all the talk of hyperthermantic flight, an industry PR who knew no better asked why we don't take aerodynamic heat into the vehicle and put it to work . . . then we met a grinning structures man who's discovered that epoxy-resin bonded fibre-glass now does many hot missile jobs with ease . . . not long ago a Redstone with delusions of Jupiter went 500 miles . . . an Army missile general figures if he waits Wilson will— . . . and in memoriam, acknowledgement to Chinaman Wan-Hoo: about 1200 A.D. he rigged 47 war rockets in fatal attempt at powered flight . . .

INDUSTRY SPOTLIGHT

By Joseph S. Murphy

Plastics Mold Missile Age

A carrying case at 150 feet from ground zero survives an atomic blast virtually undamaged . . . A guided missile nose cone stands the heat and friction generated at three times the speed of sound . . . A vibrating conveyer's springs take 10 million cycles without failure.

These are some of the wonders of reinforced plastics, the 12-year old industrial youngster which is helping smooth the way for the missile age.

Over 1,200 business and industry representatives from a dozen countries looked over the latest offerings of the reinforced plastics industry at its 12th annual Exhibit and Conference in Chicago early in February. The displays showed clearly why almost 140 million pounds of reinforced plastics were consumed in 1956—almost a third more than 1955. A similar rise is expected in 1957.

The versatility of the material, a combination of plastic resin and reinforcing material, seems limitless: from fishing rods to electronic equipment to railroad boxcars. It goes into pleasure boats, patio roofs, sports car bodies, air conditioner housings and tooling.

The aircraft industry ate up 20 per cent of the industry's output in 1956, followed by the construction industry with 16 per cent. The remainder was divided up as follows: boats 16 per cent; consumer products such as luggage, sleds, etc., 10 per cent; automotive, 8 per cent; containers, trays, tanks, 5 per cent; appliances such as laundry tubs, refrigerator liners, water softener housings, etc., 5 per cent; miscellaneous, 20 per cent.

Although polyesters still make up the bulk of the resin used in reinforced plastics, others are moving in: epoxy resin, low pressure phenolic, polystyrene, silicones, melamine, vinyl. Of the 140 million pounds of reinforced plastics sold in 1956 resins accounted for half with reinforcements and fillers making up the remaining half. Breakdown of the resins: 65 million pounds polyesters, 4 million—epoxies, half a million—phenolic and the remaining half million divided among silicones, polystyrene, melamine and vinyl.

The production of polyester resin has jumped from 3½ million pounds in 1945 to 71 million in 1956.

This year's exhibit made a big play for the consumer, displaying a large number of new products currently in mass production:

Streamlined super-market checkout counters (one is being molded every 2½ minutes with more than 7,000 already produced); lightweight translucent silo covers (the potential is thought to be in six figures); outboard cruisers (40,000 reinforced plastic boats in 1956); record players, adding machines, parcel post scales, hammer handles that would take 3,000 pounds to separate from their heads; a sports car with plastic components.

The conference stressed the growing importance of the industry in the electronic equipment field. Increasingly small parts molded of reinforced plastics premix and molding compounds are finding their way into automotive and electronic equipment. More and more, the missile industry is also turning to plastics of different types to fill its exacting and various needs.

A 74-frame color slide film and script, "Designing with Reinforced Plastics," is available for $15 from the Public Relations Department, Society of the Plastics Industry, Inc., 250 Park Ave., New York 17, N. Y. The film probes the uses of reinforced plastics in a wide variety of industries.

Kemsco to Specialize In Cryogenics Field

Kemsco, Inc. of Santa Barbara, Calif. his discontinued manufacture of maritime supplies and will devote future operations exclusively to the field of cryogenics (low temperature), according to its new president James K. La Fleur.

First major missile item it will build is a high-pressure stainless steel reciprocating pump of special design to handle liquid oxygen and nitrogen. It is intended for use at test centers and operating bases in pressurizing missile fuel chambers.

The Kemsco low temperature pump, first of which was due to enter service last month, is designed for a maximum pressure of 10,000 psi and normal operating pressure of 5,500 psi at a flow of 5 gallons per minute.

According to La Fleur, the company has equipped itself for engineering, development, modification and testing of all equipment to be used for low-temperature service. La Fleur was formerly associated with The Garrett Corp. and was chief engineer of Wall Cryogenics before joining Kemsco.

Rototest Opens Facility For 'White Noise' Testing

First independent commercial "white noise" test facility, capable of simulating the noise spectrum of jet and rocket engines up to 150 db, has been opened by Rototest Laboratories, Inc. at Lynwood, Calif.

White noise, an acoustics term that refers to all-frequency testing, is distinguished from discreet noise which refers to a given frequency.

The new Rototest facility is designed to test aircraft and missile components and equipment to the 150 db sound level intensity and produce it over a cross sectional area of 64 sq. in.

According to Rototest, at least three missile producers—Convair, Boeing and Bell—already have included "white noise" test requirements in their specifications for certain components. Company officials also said this type testing is expected to become a standard requirement of the military services in the near future.

New Supersonic LAB Under Construction

New supersonic combustion laboratory being built by Fairchild Engine Division, Fairchild Engine and Airplane Corp., is expected to be completed by mid-May. It will be used for experimental work in aerodynamics and thermodynamics.

Avco Builds R&D Center

Avco Manufacturing Corp. last month broke ground for Wilmington, Mass. for the $15 million R&D center of its Research and Advanced Development Division. Company expects new facility to be in full operation by mid-1958.

Here's another

New DC Motor by EEMCO

Type D-932, designed and produced as an alternator drive for a 400 cycle supply on a new missile.

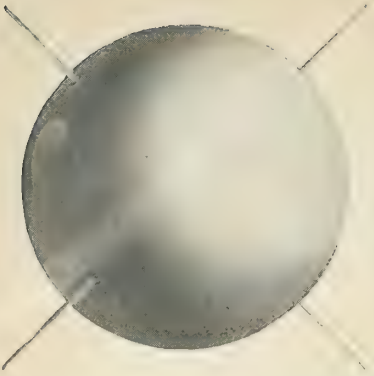
EEMCO Type D-932 DC motor operates continuously at a regulated speed of 12,000 rpm, plus or minus ½ of 1%, under the following varying conditions:

From .5 HP to 2.6 HP with a terminal voltage of 27.5 DC, plus or minus 1.5 volts.

The constant speed of 12,000 rpm is maintained by a frequency regulator that supplies the control field of the double-field stator of the motor. Type D-932 has an internal spline, and can be supplied with or without a radio noise filter, which is shown in the illustration.

Type D-932 is another in the series of new AC and DC motors being custom designed and produced currently by **EEMCO** for the latest missiles and supersonic jet aircraft. In fact, there is an **EEMCO** motor or actuator system on the majority of such new weapons now in production or projected for use by our Armed Forces.

This, we believe, is an expression of confidence in **EEMCO**, which for the past 15 years has specialized exclusively in the design and production of motors and actuators, both linear and rotary, for prime and subcontractors in the aircraft industry.



SPECIFICATIONS FOR TYPE D-932

Type: DC motor for alternator drive for 400 cycle supply on a missile.
Speed: Continuous at 12,000 rpm, plus or minus ½ of 1%.
Speed Control: By frequency regulator supplying control field.
Load: From .5 HP minimum to 2.6 HP maximum.
Terminal Voltage: 27.5 DC plus or minus 1½ volts.
Weight: With radio noise filter—13.9 lbs. Without same—12.4 lbs.

Industry Highlights

By Fred S. Hunter

Some 80 past and present associates of Dr. W. B. Klemperer, chief scientist for the missiles engineering department at Douglas, organized a surprise dinner to observe his 20th anniversary with the company in a fitting and proper manner. Klemp is an old Zeppelin man who has been through a lot since then and the party brought out considerable reminiscing. Such as how before World War II the Douglas company began to give consideration to the intercept problem and put Klemp to work on it. He came up with a big fat report that Douglas thought a highly intelligent piece of work. It was so good Douglas decided Wright Field should be given the opportunity to see it. Wright Field liked it too. So much so it promptly slapped a great big secret stamp on it. Yep, they had secrets in those days, too. After that no one at Douglas was allowed access to the report, including Klemp himself.

The Klemperer dinner reminded Bernard Benson, president of Benson-Lehner Corp., of the early days of missile firing. First, they chased the cows off the range. Then they touched a few wires together and counted one, two, three—GO! "That was before we learned to count backward," grinned Benson.

•

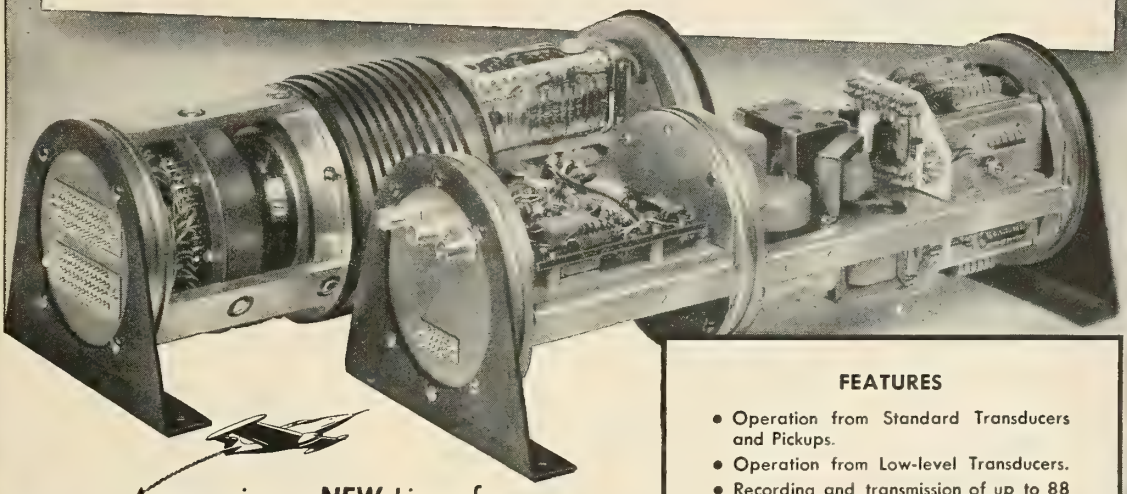
Magnitude of an ICBM test program is illustrated by the fact that Convair has had personnel assigned to the Air Force Missile Test Center at Patrick AFB since 1953, where one of these days, now four years later, the *Atlas* will be launched over the range extending out into the Atlantic. By the time Convair is up to full-scale test operations on the *Atlas* it will have a payroll of 450 people at Patrick. Convair also has had test personnel at the Edwards Rocket Base in California since 1955, two years, working on the test program for the *Atlas* power plants.

North American's engine test site at Santa Susanna represents another example of what rocket testing entails. Rocketdyne has 19 test stands at Santa Susanna and averages one test per stand per shift (2) per day. It uses 250,000 feet of oscillograph paper a month and 300,000 feet of magnetic tape recording the data.

Little things add up: Lockheed Missile Systems division saved 1000 man-hours on a mockup job by switching from plaster to stryofoam, a lightweight plastic that can be cut to any shape and then solidified by an overcoat of plastic-painted glass cloth. A safety committeeman at MSD observed that constant hammering broke down the surfaces of blunt-edged chisels, leaving sharp rough ends that chipped off into flying bits of steel that imbed themselves into workers' fingers, hands and arms. He suggested that chisel tops be kept round and polished. An inspection turned up only one that did not need repolishing.

•

Engineering data unit at Atomics International has replaced the standard file cabinets formerly used by engineering drawings with an open library-type steel shelf rack. Boyd Corwin, unit supervisor, estimates the 12 x 7 ft. open rack takes the place of 20 file cabinets, a saving of 50% in floor space and a substantial amount in equipment cost. Filing is easier, so handling time is reduced.



•

Tripling of Northrop Aircraft's Torrance facility is related to growing projects on the intercontinental Snark . . . Marquardt Aircraft netted a substantially increased profit in 1956, but Roy Marquardt says the earnings will be reinvested in the business to pay for future growth.

NEW FROM ASCOP

LOW LEVEL PW MULTICODERS

Open a Whole New Field of Mobile Instrumentation!

Announcing a NEW Line of

SUPERSENSITIVE PW AIRBORNE EQUIPMENT

For Remote Measurement, Recording, Transmission

The new ASCOP D Series PW Multicoders provide, for the first time, supersensitive, low-level remote measurement of data from airborne vehicles. The extremely high input sensitivity, fast sampling rate, and wide selection of data channels (up to 88) of these new Multicoders . . . together with their critical accuracy, ultra-high altitude pressurization, and rugged design . . . suit them ideally to today's most important testing and prototype applications involving recovery and repeat use.

Provides A Complete Data System

The new ASCOP Multicoder, combined with ASCOP M Series Ground Station Equipment and suitable transmission or recording equipment, constitutes a complete data handling system that is easy to operate, flexible in application and provides simplified real time reduction. ASCOP also produces a complete line of PW Data Systems and equipment, Telemetering sets and High and Low Speed Rotary Sampling Switches. Contact ASCOP regarding your present program *today*.

FEATURES

- Operation from Standard Transducers and Pickups.
- Operation from Low-level Transducers.
- Recording and transmission of up to 88 data channels.
- Ease of data reduction.
- Pressurized for very high altitudes

SPECIFICATIONS

- **Input Sensitivity:** 0-15 mv or 0-30 mv
- **Input Circuit:** Differential balanced to ground
- **Data Channels:** 43 or 88
- **Sampling Rate:** 20 or 10 samples per second per channel
- **Output:** Standard pulse width
- **Power Requirements:** 115V, 400 cycles

ASCOP

WE PROVIDE THE LEVER . . . YOU MOVE THE WORLD

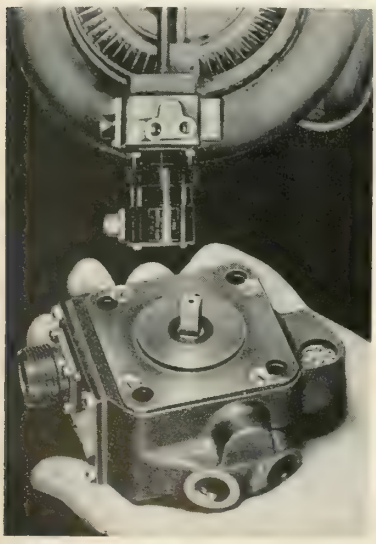
NEW MISSILE PRODUCTS

Robertshaw-Fulton Unveils Liquid Level Switch

A 9-ounce liquid level switch which utilizes radioactive means to sense and control fuel levels in supersonic aircraft and missiles has been unveiled by Robertshaw-Fulton Controls Co. The system consists of a 2-oz. ½ x 4¼ in. probe and a 7-oz. 3¾ x 2 5/16 x 1¼ in. transistorized amplifier of rugged construction to meet aircraft and missile needs.

The sensing probe contains a hermetically-sealed beta source and a beta detector (geiger mueller tube) mounted inside the fuel tank or cell. These are separated by a small cavity into which the liquid flows.

When no liquid is present, radioactive particles pass from the source to the detector; when liquid enters the cavity, the radioactive particles are absorbed and the radiation level is reduced.



The R-S system converts this change in radiation to an electrical signal, amplifies it by a transistorized circuit, then actuates a relay that is used to energize warning lamps, valves or servo motors to correct the fuel distribution on the aircraft or missile.

Company officials place the signal response time at about 1/20th of a second and its accuracy at —1/10 in. whether liquid level is rising or falling. Switch works on 28 volts d-c at 0.05 amps.

Circle No. 225 on Subscriber Service Card.

SPEED GOVERNOR

A new speed governor and tachometer switch proposed for a variety of

applications in aircraft, drones and missiles has been introduced by The Lee Co.

Essentially a "droop" type governor with a 7% permanent droop, the Lee development has been designed for direct throttling of a propellant to a gas generator and has been used for throttling of JP-4 fuels on small jet engines.

Company officials, however, visualize its potential as a speed regulator on auxiliary power units, overspeed protection device for turbo pump sets, and for sequencing and control of remotely operated engines as on drones or air-launched missiles.

The governor weighs about 1 lb. and measures 3.18" x 4.31" x 1.71" overall.

Circle No. 204 on Subscriber Service Card

ROCKET TEST STAND

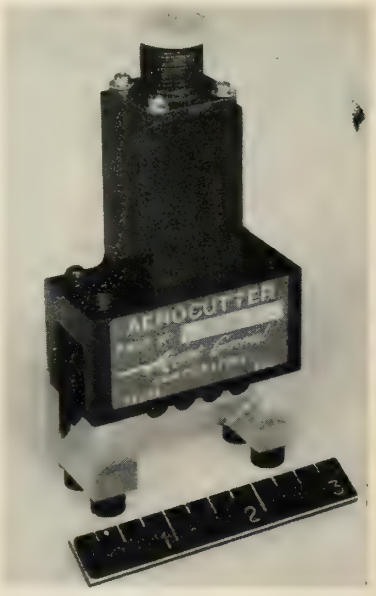
Aerophysics Development Corp. subsidiary of Curtiss-Wright Corp. has developed a vertical balancing machine capable of dynamic balancing of rocket motors, rotating launchers, and turbo machines weighing up to 5,000 lbs. in weight.

It is said to handle rocket motors with thrust ratings up to 20,000 lbs. and diameters up to 36 in. Turbo machines or components, such as flywheels, can be accommodated at dimensions up to 10 ft. in length and speeds of 10,000 rpm.

According to ADC, rotating units weighing several hundred pounds have been balanced to an accuracy of about 1,000,000th of a radian. Experience showed that test and correction cycle could be completed in about one hour.

The new balancer will also measure dynamic unbalance of a spinning rocket motor when shut down or firing. In addition, with slight changes in suspension system, it can be adapted for measuring jet misalignment of rocket motors ranging in capacity from 100 to 20,000 lbs. thrust.

Circle No. 206 on Subscriber Service Card



LOW-NOISE BLOWER

Turbo Research Corp. has developed the Model 101 centrifugal blower intended to fill the gap in pressure range between previous centrifugal and axial types used in aircraft and missiles.

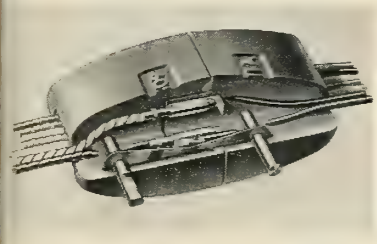
The Model 101, featuring a drastic reduction in noise levels, is rated to deliver 1300 cu. ft. of air per minute at 8,000 rpm against a discharge head of 4 psig. Literature available.

Circle No. 208 on Subscriber Service Card

CARTRIDGE-ACTUATED CUTTER

Aerojet-General Corp. has introduced a new cartridge-actuated cutting device that weighs only one pound and occupies 7.5 cu. in. of space for airborne use in severing aircraft and missile system lines.

The Model AGX-1800 Aerocutter, as a typical example, is designed to sever four stainless steel tubes of ¼ in. diameter and .035 in. wall thickness while they are pressurized to 150 psi with corrosive fumes.



As an added feature, the unit will

cut the tubes so that one end may vent to ambient pressure and swage the other against an anvil to seal it and prevent further flow. It is fired by an electrical impulse which actuates a non-corrosive propellant and may be reloaded for repeated use.

In addition to airborne applications, the company proposed use of the Aerocutter in safety systems for nuclear reactors, as well as for hydraulic or pneumatic devices and mobile ground equipment.

MISSILE CONNECTORS

New series of electrical connectors which feature the molding of insulation directly onto contacts and leads has been introduced by Alden Products Co.

The new design, intended for use in fool-proof, tamper-proof cables for critical aircraft and missile operations, calls for molding of contacts and leads with one hot shot of connector insulation into connector bodies arranged integrally within their cables.

Among special IMI (integral molded insulation) connectors unveiled by Alden is an umbilical disconnect for missile use.

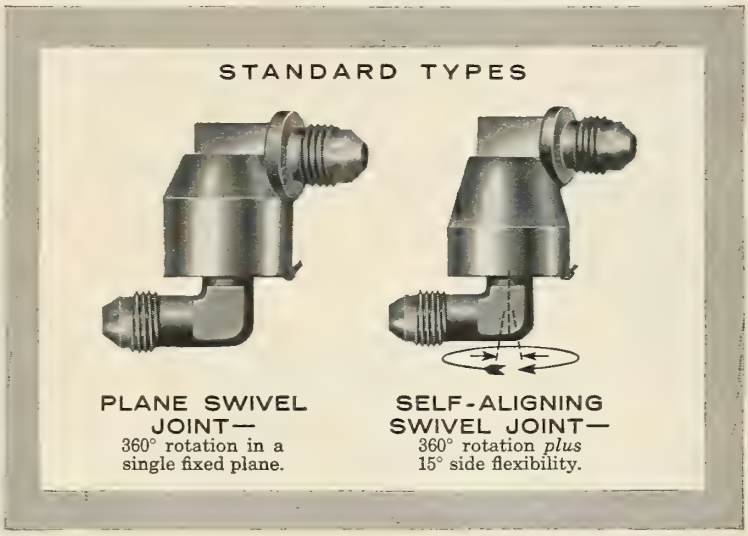
PROPELLANT PUMP



A new ball-piston type missile fuel pump designed for handling low viscosity, low-lubricity, highly corrosive propellants such as normal propyl nitrate has been announced by General Electric Co.'s Aircraft Products Dept.

At 260°F, the GE pump is rated to deliver 0.50 gallons of propyl nitrate per minute. In addition, GE states, use of corrosion resistant materials in its construction makes the pump suitable for high-temperature operation with many other exotic missile fuels.

"TAPE-ON" SURFACE TEMPERATURE RESISTORS

for Temperature Telemetering

- NO THICKER THAN A PIECE OF TAPE
- OUTPUT UP TO 5 VOLTS WITHOUT AMPLIFICATION
- AVAILABLE IN VARIOUS RANGES FROM −300° to +400°F.
- RESISTANCE CHANGE OF 100 OHMS OVER SPECIFIED RANGE
- NO HOLES TO DRILL — QUICK AND EASY "TAPE-ON" INSTALLATION

Trans-Sonics Type 1371 "Tape-on" Surface Temperature Resistors are precision resistance thermometers with a platinum resistance winding as the sensing element. These resistors which are no thicker than a piece of tape may be applied to *any surface* whose temperatures are to be measured. In a commutation circuit, they modulate standard telemetering transmitters without amplification. The new Type 1371 "Tape-on" Surface Temperature Resistors may be added to an installation using other Trans-Sonics temperature transducers without any further circuit modification. Each resistor is furnished with 6" long fibreglas-covered constantan leads. Write for Bulletin 1371 to Trans-Sonics, Inc., Dept. 9.

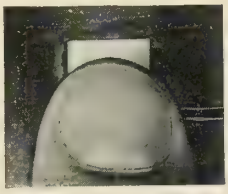
*Reg. Trademark

SPECIFICATIONS

SIZE: ¼" x 5/16"

Accuracy: ±2% of full scale range

Precision: ±0.5% of full scale range



Maximum Continuous Current: 20 ma rms (averaged over 1 second)

Environmental Operation Conditions

Vibration: 1" double amplitude, 0 to 22 cps ± 25g, 22 to 2000 cps

Shock: 100g in any direction, per paragraph 4.15.1 of MIL-E-5272A (10 milliseconds shock)

INSTANT INSTALLATION

As easy to apply as a thumb print.

For Transducers, See Trans-Sonics

Trans-Sonics, Inc.

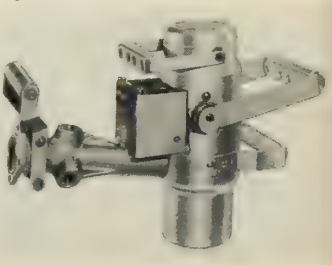
MISSILE RECORDER

A miniature magnetic tape recorder, already used to secure skin temperature data in high-speed, high-altitude flights of Aerophysics Development Corp.'s HTV (hypersonic test vehicle) has been introduced by North American Instruments, Inc.

The new units—weigh 2¼ lbs. and measure 4 in. in diameter by 5 in. high making them ideal for use in collecting aerodynamic data from missiles too small for conventional telemetering equipment.



According to E. Bollay, NAI president, a single recorder has been recovered and reused eight times in missile tests to date at Holloman AFB, N. Mex. In all, company officials say some 12 different firms are using the units in rocket and missile testing.

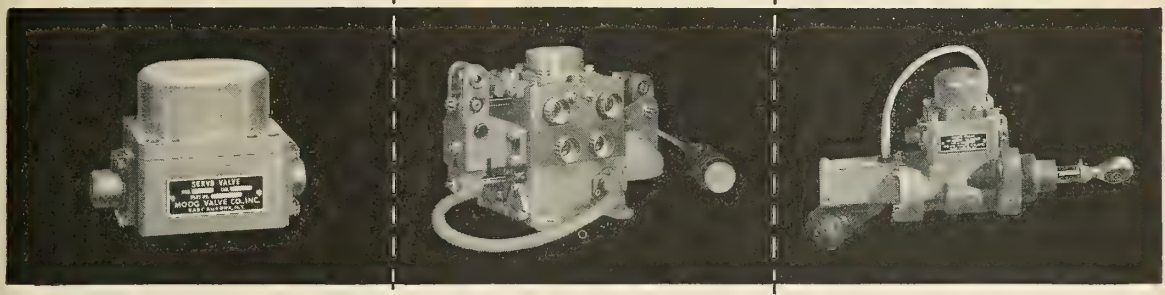
ACID TRANSFER NOZZLE

A missile oxidizer transfer nozzle developed by Lear, Inc., Lear-Romec Division, is designed especially for handling fuming nitric acid and is rated for operation at temperatures extending from —65° to +140°F.

The Romec nozzle, designated Model RR13110, meets requirements of Spec. MIL-N-25556 and uses only the purer aluminums and special stainless steel alloys to resist the corrosive action of HNO_3.

Normally, two nozzles are needed to transfer liquid propellants or oxidizers from the supply tank to the missile—one for filling and the other for venting the tank. The Lear nozzle provides a teflon gasket flange to which the vent or fill hoses are attached.

The Model RR13110, which is rated to handle a flow of 100 gallons per minute, incorporates two safety interlocks in its construction. The first prevents inadvertent opening of the flow control valve before the nozzle is attached and locked to the adapter on the missile tank: the second prevents unlocking nozzle from adapter while the flow valve is open.



Lear-Romec also produces Model RD13040 adapters used on the missile tank and servicing trailer in conformance to Spec. MIL-A-25555. Literature available.

From MOOG . . . **Advanced Electro-Hydraulic Servo Components**

Moog is the industry's leading producer of electro-hydraulic servo valves. This leadership has been achieved by advanced valve design resulting in high performance, high quality, reliability and efficient manufacture. The same creative approach applied to industry's newer problems has resulted in the introduction of Moog Dual Input and Servo Actuator units.

These recent achievements in the creation of advanced custom designed electro-hydraulic servo components are evidence of Moog's continuing progress.

SERVO VALVE

• These proportional "dry motor" electro-hydraulic servo valves feature high dynamic response, sensitivity, linearity and reliability. Light-weight and compact, they are also available in custom designed versions for special or advanced applications.

DUAL INPUT SERVO VALVE

• This new component provides for positioning of aircraft control surfaces by summing mechanical and electrical inputs without external use of mechanical linkages. Use of an entirely new concept offers improved performance, system simplification and saving of space and weight.

SERVO ACTUATOR UNIT

• Custom designed integrated assemblies include actuating cylinder, electro-hydraulic servo valve and feedback sensing device. In a closed loop, actuator displacement is a function of input signal.

TO THE ENGINEER IN A "HURRY"

Axiomatically, to get somewhere in a hurry, you get aboard something that moves pretty fast.

If your "somewhere" is a career in engineering, consider Moog. From three founders to five hundred employees within five years, we are today the industry's leading manufacturer of advanced electro-hydraulic servo components. Our engineers made this possible by continuous pioneering of the new and successful developments in the field. As our rapid expansion continues, we have many openings at all levels for qualified personnel.

Best time to get aboard is now.

From Electro Instruments comes a revolutionary new concept in digital instrumentation.

transistorized, plug-in modules for precision measurements of dc, ac, ohms and ratios

NOW GET MAXIMUM FLEXIBILITY FOR CUSTOM APPLICATIONS WITH STANDARD, OFF-THE-SHELF MODULES

Check these new specifications and features—the result of thousands of applications and field experience of more than 1,000 digital instruments

Fully transistorized circuits in the new modules provide

1. Increased reliability.
2. Reduced power consumption.
3. Low heat dissipation.
4. Miniaturized packages.
5. Elimination of radio noise and line transients.

New specifications and features

1. Wider dynamic range covering all voltages from **100 microvolts to 1,000 volts,** resistance range from **10 milliohms to 10 megohms**—in **single** instruments!
2. Input power frequencies from **50 to 400 cycles!**
3. New balance logic speeds down ranging!
4. Automatic ac ranging from 30 to 10,000 cycles!
5. Controlled stepping switch drive increases switch life by a factor of **three!**

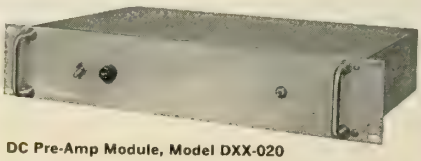
Complete flexibility

1. Universal 3½" x 19" x 12" chassis with mounting hardware for **any** rack.
2. **No** modifications required for operating printers, IBM Punches, etc., or for combining with auxiliary E-I input modules or instruments.
3. **All** contacts readily accessible at rear panel on connectors.
4. With auxiliary plug-in modules, digitized data is provided in printed form, punched cards or tape with **no** modification to basic measuring instruments.

Circle No. 44 on Subscriber Service Card.

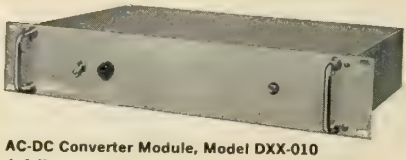
BASIC MODULES

Universal Power Module, Models DXA-000 or DXB-000



Supplies *all* power and reference voltages for other E-I modules. Power and reference supplies and stepper drive amplifier are transistorized. Powers one or more modules.

Calibration: Automatic
Reference Stability: 0.01% from 40° to 125° F.
Input Power: 115 volts, 50 to 400 cycles.
Write for Bulletin 175-1



DC Switch Module
Model DVX-400: 4 digits; **Model DVX-500:** 5 digits

Contains Digital Potentiometer. Provides visual in-line read-out of digits, polarity, decimal point. All contacts accessible at rear panel connector. Front and rear panel input connectors. Power supplied by Universal Power Module.
Write for Bulletin 175-2

DC Pre-Amp Module, Model DXX-020

Input: 1 range scale, gain of 10.
Output: 0.0001 to .9999 volts. **Linearity:** 0.01%.
Gain Multiplication Accuracy: 0.01%.
Input Power: 115 volt, 50 to 400 cycles.
Drift: 10 microvolts per hour.
Write for Bulletin 175-5

AC-DC Converter Module, Model DXX-010

A fully transistorized AC-DC converter.

Accuracy: 0.1% of reading, or 2 mv.
Frequency Response: 30 to 10,000 cycles.
Range: .0001 to 999.9 volts.
Zin, AC: 1 meg. on the 1 volt scale, 10 megs. on other scales; 20 mmf.
Ranging: Automatic. **Reading time:** 3 seconds, average.
Write for Bulletin 175-4

Resistance Switch Module
Model DOX-400: 4 digits; **Model DOX-500:** 5 digits

Contains balance circuit, bridge ratio arms. Provides visual in-line read-out of digits, range. All contacts accessible at rear panel connector. Power supplied by Universal Power Module.
Write for Bulletin 175-3

Using E-I's new, transistorized, modular design, any precision instrument for measuring DC, AC-DC, Ohms, DC and AC ratios can be constructed from basic units!

NEW LITERATURE AVAILABLE—Write for new short form Bulletin 175 containing information about the new Electro Instruments modular design.

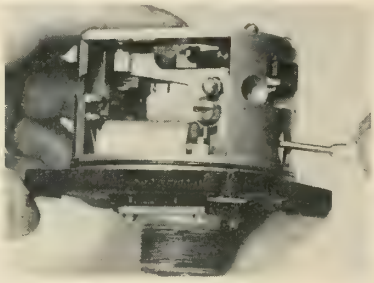
MULTI-CHANNEL PROGRAMMER

A small programming device, the MPR-13, provides up to 13 channels for electrical programming of either repeat or random cycling. Weight is 3 lbs. 10 oz. and size is 2 x 3 x 6 inches. The device uses a moving insulating tape marked lengthwise in time and divided into 13 channels through punched holes and slots in the tape.

As the tape is advanced contactors close for a period equal to hole size or slot length. A magnesium casting is used for low weight and high resistance to shock and vibration. The Photographic Products, Inc.

Circle No. 217 on Subscriber Service Card

MICROWAVE DIODE



A silicon diode for use as a low-level detector in missile guidance, beaconing and telemetry has a theoretical tangential sensitivity of —53 dbm at 9000 mc for a receiver bandwidth of 10 mc.

Use of the MA-408B is said to give an improvement of 4-5 db when it replaces IN23C mixer crystals in low-level circuitry. For highest sensitivity a dc bias of +50 microamperes is recommended. The Microwave Associates, Inc.

Circle No. 216 on Subscriber Service Card

ACCELEROMETER

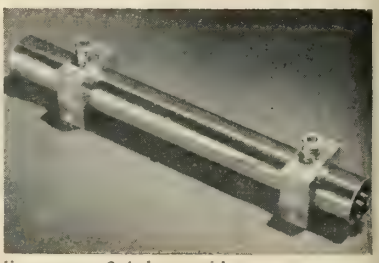
An accelerometer which has a caging mechanism to prevent wear when the unit is not in use offers accuracy to ½% and an operating temperature range from —50°C to 100°C. The caging mechanism of the new Series LA07-0100-1 is electrically released when it is in use.

Vibration from 10 to 2000 cps to 10g can be withstood and the device is shock-resistant to 40g or to 100g on special order. Rated linearity is 0.5 to 1.0%. Potentiometer pickoff is 500 to 20,000 ohms, and resolution to 0.15% is obtained. Humphrey, Inc.

Circle No. 218 on Subscriber Service Card

TRANSISTORIZED INVERTER

A dc to ac inverter with no moving parts has been designed to provide 300 va using transistors. Weighing 5.5 lbs. and occupying a volume of 96 cu. in. the new CW-1029 will withstand vibrations of 10g between 10 and 2000 cps.



Use of the inverter is planned in the second stage of the Vanguard vehicle as a power supply for servos. Efficiency is rated as 60-70% with a harmonic content of less than 5%. Cooling is through the mounting base of the unit. Stability is within 0.2 cycles. The Electrosolids Corp.

Getting Talos Off to a Good Start

DESIGN
ENGINEERING
DEVELOPMENT
PRODUCTION

For its initial flight, the XX*-ton Talos ram-jet missile is pushed skyward by a powerful booster rocket. In a split second from launching, internal pressures are up to XXXX* psi . . . nozzle temperatures to XXXX* F. To design and produce a unit to endure such sudden torture called for an unusual combination of specialized engineering and fabricating skills. A major responsibility for the Talos rocket case was assigned to The M. W. Kellogg Company

Since 1951, M. W. Kellogg has been closely associated with the development and production of propulsion units for a wide range of missiles. Kellogg's most recent contribution is the development of reinforced plastic for rocket cases, using a unique filament winding method which produces structures of unparalleled accuracy and light weight.

INDUSTRY BAROMETER

An analysis of Defense Department expenditure estimates reveals that in fiscal 1958 about 17 per cent of major procurement and production funds will be spent for guided missiles. Thirteen per cent will go for missiles during fiscal 1957.

During FY 1956, approximately $10 out of every $100 spent by the three services for major procurement and production was for guided missiles. In 1951, the rate was only $.50 out of every $100.

Of the three services Army has had the greatest growth in missile expenditures. Spending for missiles equalled 25 per cent of major procurement expenditures in 1956, and in 1958 missiles will account for 41 per cent. The 1956 missile expenditure percentages for the Navy and Air Force were 5 and 9 per cent, respectively; and in 1958 they will be up to 7 per cent and 17 per cent, according to DOD estimates.

Major procurement and production expenditures include, in addition to guided missiles and aircraft and related procurement, money paid out for ships and harbor craft; combat vehicles such as tanks, infantry assault and armored vehicles; support vehicles—trucks, ambulances, busses; artillery, including anti-aircraft; weapons; ammunition; electronics and communications equipment such as radar, radiac and infrared, and meteorological equipment; and production equipment and facilities. Other items not classified elsewhere, but whose size, unit value, or procurement and production problems indicate inclusion under the general category of major procurement and production, are also accounted for in this category. Such items are railroad equipment, major materials handling equipment, construction equipment and special training devices.

Guided missiles, as a part of the major procurement category, include, in addition to the complete missile with integral armament components, expenditures for the following: launching, guidance and control devices, boosters and sustainers; propellants (other than standard petroleum fuels); special tools and ground handling equipment peculiar to the handling of missiles; unmanned aerial targets, excluding target drones used primarily for training. The missiles category excludes standard aircraft engines not procured for use on guided missiles, and missiles and components for research and development or still in the research and development stage.

Bell Applies New Microwave Power Find

First successful application of a recently discovered new source of microwave power has been achieved by Bell Telephone Laboratories.

Using what is known as the "maser" principle, a new electronic device using solid-state materials for radio energy generation and amplification was operated at Bell's Murray Hill Laboratories.

The "maser" was first demonstrated in molecular beams of gases in 1954 by Prof. C. H. Townes at Columbia University.

It means "microwave amplification by stimulated emission of radiation." The principle makes use of spinning electrons in a solid cyrstalline substance in the field of a strong electro-magnet.

Equipment used by Bell included a waveguide cavity containing the crystal. The whole assembly was immersed in liquid helium. The cavity has two resonant frequencies.

One was equal to the frequency of oscillation and the other to the energizing source. The crystal, paramagnetic salt diluted with a diamagnetic substance to reduce electron interaction, was located at the point of maximum field intensity—2,800 oersteds.

When a 17,500-mc energizing signal at about 100 milliwatts was brought into the cavity, the spinning electrons underwent a transition from one energy state to another and self-sustained oscillations occurred at 9,000 mc. Power output was 20 microwatts.

Bell scientists say the new oscillator has an attainable noise figure hundreds of times lower than presently available devices. This could result in development of new long distance communication systems.

In such uses the device could be easily tuned by varying the applied magnetic field and bandwidth would be around 100 mc.

AIA Hits Congress' Report On Recruitment

Aircraft Industries Assn., in a sharp rebuttal to Congressional criticism of costs in aircraft and missile engineering procurement, has charged that Navy Department figures were erroneously interpretated by a House group in arriving at its statistics.

Directing its comments at a report issued by the House Subcommittee on Manpower Utilization and Departmental Personnel Management, AIA officials explained that the fault rested with subcommittee calculations which based recruiting costs on net hires rather than on the Navy's system of gross hires.

Proper adjustment of figures cited by subcommittee chairman, Rep. James C. Davis (D-Ga.), would scale Davis' average cost of $1,317 per new employe down to the Navy figure of $808, AIA pointed out.

Citing an extreme example of the inconsistency of Congress approach, AIA asked what cost per new employe would be used if a firm spent $10,000 to recruit 10 new employes and in the same period lost 10.

The industry association also took issue with a comparison by chairman Davis of defense contractors and commercial business firms leading to a conclusion that the former spent more than 10 times as much for recruiting. AIA simply noted that the Congressman unfairly balanced the recruiting costs of 37 defense contract firms against similar costs of only 17 commercial firms.

Concluding its criticism, AIA noted that Congress took no testimony from industry in its investigation and urged that it confer with industry before launching any "corrective" program, as such action could have serious effects on the overall defense program.

Student Engineer Program Launched At Fairchild

Fairchild Engine Division, Fairchild Engine and Airplane Corp. has launched a cooperative student engineer program involving six major engineering schools to help alleviate the shortage of trained engineers.

The program is arranged to combine, in a five year span, four years of college education and two years of actual experience in aircraft powerplant design and development. Schools associated with the Fairchild program are Univ. of Cincinnati; Univ. of Detroit; Antioch College; Georgia Tech; Drexel Institute and Northeastern University. Project at Fairchild is being coordinated by T. F. Hammen, Jr.

Acme Gets AMC Award

Acme Precision Products, Inc. of Dayton, O. has received a $5,888,851 contract from Air Materiel Command for a new liquid oxygen plant.

EMPLOYMENT

ELECTRO-MECHANICAL ENGINEER

ICBM NOSE CONE DEVELOPMENT

PRESSURE SYSTEMS

SALARY to $11,000

The Missile & Ordnance Systems Department of General Electric, prime contractor for the development of the ICBM and IRBM nose cones, has an opening of unusual potential on its staff.

Required: ME, EE, or physics graduate with 5 to 10 years' experience in design, development and evaluation of barometric switches and pressure probes as applied to ordnance and missile systems.

Responsibilities: technical direction, functional leadership and project integration of three to eight engineers.

The environment is completely technical and professional. We are a research and development laboratory affiliated with one of the world's largest, most diversified and progressive industrial organizations. We hold prime contracts of a long-term nature with all of the armed services. Salary and benefits are liberal. Philadelphia location. Excellent facilities and equipment.

The Manager of our Arming and Fuzing Component Equipment Design Operation would be pleased to review your resume. A personal interview with him in Philadelphia will be arranged at our expense if your qualifications are appropriate. If you prefer, you need not reveal the name of your present employer.

Please write to

An Announcement

OF FIRST IMPORTANCE TO EXPERIENCED ROCKET ENGINEERS AND SCIENTISTS

- *Reaction Motors initiating big new Research and Development Program*
- *Key spots offered to men who have already made a name for themselves in Rockets*

If you're one of the relatively few trained rocket men in America, your experience will pay off handsomely at Reaction Motors. The first rocket company in America, RMI is now entering its period of greatest expansion, a period that will see far-reaching developments in America's fastest-growing industry. Your participation in RMI's program during this crucial period is your best guarantee of leadership in the industry. In a job like one of those listed below you'll be strategically placed for both achievement and advancement.

1. Senior Design Engineer

Prefer ME or AE degree and a minimum of 6 years experience in aircraft engines or airframes. You should have extensive design experience, including plenty of board time, shop contact, structural design, stress analysis. You will be working directly with design engineers and layout draftsmen on design of light weight, complex structures.

2. Instrumentation Engineer

BS minimum in mechanical, aeronautical or electrical engineering; 3-5 years experience on aircraft engines. Must be familiar with the application of instrumentation to testing of rocket or other aircraft engines, the utilization of currently available instrumentation, or the modification and adaptation of such instrumentation for particular requirements and wide limits of flow temperatures, pressure, thrust, etc.

3. Stress Engineer

Degree in engineering or applied mechanics. Required experience in mechanical design with emphasis on stress analysis: 3 years for an engineer, to 6 years for the senior engineer. Must be able to handle and/or supervise involved analyses—including the effects of dynamic forces, high temperature gradients and high pressure differentials—under conditions where light weight is vital.

4. Project Engineer

BS or MS in ME, AE, or ChE—with at least 5 years experience in the design, fabrication and test of rocket thrust chambers, gas generators and ignitors. Project engineers also needed with background which includes knowledge of principles and problems associated with design, development and analysis of hydraulic or pneumatic power plant controls and systems.

RMI'S 6 MAIN PROJECT AREAS INCLUDE:

MISSILES • PILOTED AIRCRAFT • LAUNCHING DEVICES • GROUND SUPPORT EQUIPMENT • LIQUID AND SOLID PROPELLANT CHEMISTRY • NUCLEAR ROCKETS

For additional information on these or any other positions, drop a note or send complete resume in strict confidence to:

HOW DO YOU GROW AT ARMA?

Through diversification!

In our recent advertisements, we spoke of the growth opportunities offered by Arma. Almost immediately, perceptive engineers began writing us, asking for more information.

"How *does* an engineer grow at Arma — precisely?"

Our answer, in a word, is *diversification.* Arma offers one of the *broadest programs of work diversification* in the electronics field.

At Arma, an engineer follows a project from original design, right through final production. As a result, our engineers and scientists are exposed to many activities not usually found under one roof — areas into which they can grow, as their abilities and interests lead them.

Here are some of the areas — 69 examples — in which Arma concentrates its efforts in:

MISSILE CONTROLS & GUIDANCE and FIRE CONTROL

1.0 SYSTEMS DEVELOPMENT
- 1.1 Digital Computers
- 1.2 Autopilots
- 1.3 Infrared
- 1.4 Electromagnetic Devices
- 1.5 Gyroscopics
- 1.6 Inertial Platforms
- 1.7 Missile Guidance
- 1.8 Fire Control
- 1.9 Servos

2.0 PROJECT ENGINEERING
- 2.1 Airborne Fire Control
- 2.2 Airborne Armament
- 2.3 Air-to-Air Missiles
- 2.4 Semi-Automatic Test Equip.
- 2.5 Air Traffic Control

If you want to participate in the growth that *must* come to a man working in so diversified an environment, write and tell us the area in which you're most interested. (Or use the coupon below.) Your confidence will be respected, and you will hear from us promptly. If you prefer, forward confidential resume. No reference contact without your permission.

Technical Personnel Department M-674

ARMA

Division of American Bosch Arma Corporation
Roosevelt Field, Garden City, Long Island, N. Y.

Gentlemen:

☐ Please send me additional information concerning the job numbered _____

☐ Or, additional information concerning the area of _____
(state interest if not in above listing)

NAME _____

ADDRESS _____

CITY _____

ZONE _____ STATE _____

Missile School Marks 4th Year

HUNTSVILLE, Ala.—One of the nation's most important but least appreciated defense agencies is observing its fourth anniversary here this month by getting a new name and putting the Army's new *Lacrosse* surface-to-surface and *Dart* anti-tank missiles on public view for the first time. In fact, it exhibited the Army's whole family of missiles, except the late models of the IRBM and ICBM.

The Ordnance Guided Missile School—now the U.S. Army Ordnance Guided Missile School, by official decree—held an open house, showed movies, displayed its sleek weapons served cake and coffee—and even allowed cameras.

The School has been somewhat overshadowed in this area by the presence of its more spectacular sister installations, Redstone Arsenal and Army Ballistic Missile Agency.

Yet in four years it has provided the nation with the nucleus of its new missile defense units. More than 5,000 key officer and civilian personnel have been "graduated" from its courses in the use and maintenance of the *Nike Ajax, Corporal* and *Redstone* missiles and are now on duty with missile units in the field and at key headquarters.

They are the beginning of a vastly expanded program that will see thousands of men—and some women—trained to handle the increasingly potent and varied arsenal of missiles available to the Army and other branches of the service. A $7 million building program is under way to provide training in *Nike-Hercules, Dart, Sergeant* and *Lacrosse* missiles.

Navaho Cutback at NAA Forces Layoffs

Reduction by the Air Force of a portion of the second-stage test vehicle (X-10) in the *Navaho* missile program has resulted in a reduction in force at North American Aviation's Downey and Los Angeles *Navaho* activities.

However, a portion of the layoffs will be absorbed by attrition (not hiring replacements), and NAA said it will also attempt to re-assign employees who can qualify for job openings in other divisions.

The remaining layoffs, of undisclosed number, will be made by NAA in accordance with existing union agreements. The force reduction became necessary when the Air Force

rdered the company to divert ma-
rials from X-10 test vehicles to more
dvanced stages in *Navaho* missile de-
elopment, essentially introducing a
stretch-out" in the *Navaho* program.

Marquardt Aircraft Grants General Pay Hike

Marquardt Aircraft Co., producer f the ramjet powerplant for the Boe- g *Bomarc,* announced a general wage crease of 4% for salaried employes ffective on February 18. Hourly em- loyes also received a 7 to 12¢ per our pay hike.

The new increase, which affects bout 2,680 personnel, increases Mar- uardt's top technical and office hourly cale to $3.12 an hour and top factory rade to $2.93.

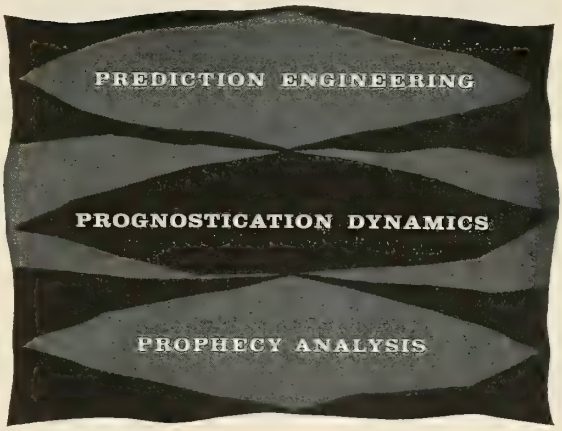
Culver City Quarters For Douglas Engineers

Douglas-Santa Monica division as shifted about 160 missile engineer- g personnel to new quarters at Doug- s A2 location in Culver City, Calif. s a result of the growth of missile ngineering work at Santa Monica.

Company is now constructing a ant balcony that will add 45,000 sq. . of office space for the division's issiles engineering department.

New GE Contract For J79s May Be For Regulus II

General Electric Co. has an- ounced receipt of a $53,414,557 Air orce contract for additional J79 jet ngines but did not identify the air- aft for which they are slated.



The J79 is presently used in the ockheed F-104A and Convair B-58 personic bomber, but is also known power the supersonic Chance ought Regulus II missile, a possible planation for the omission of air- aft mention in the announcement.

Douglas, Northrop Get Missile Contracts

Northrop Aircraft, Inc. has re- ived a $3,366,647 contract from Air ateriel Command covering flight sting of "undisclosed equipment" pre- med to be a missile.

Douglas Aircraft Co. at Sacra- ento, Calif. received a $1,305,528 MC award for guided missile (*Thor*) velopment work.

PHYSICISTS • GAS DYNAMICISTS
ELECTRICAL and MECHANICAL ENGINEERS
for

These are not really the titles that Republic Aviation uses to describe the work of its Dynamics Analysis Section — but they justifiably could be.

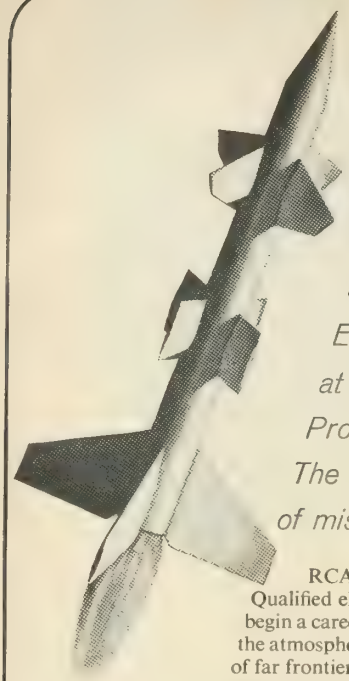
Why?

Because the work involves the analysis of controls systems in the proposal and design stage — before the mathematics and engineering principles ever take concrete form.*

In Republic's Dynamics Analysis Section you will find some of the best engineering and physics minds in the country. They work in small groups predicting the performance and guiding the design of control complexes for advanced jet-craft and missiles — complexes based on electronic, pneumatic, hydraulic and thermodynamic units.

Openings still exist at Republic for engineers and physicists well grounded in fundamentals. You will find opportunities for using servo design techniques, analog computer methods and the strategems of operations analysis — as well as the more orthodox mathematical tools — in solving problems of varied and stimulating nature.

Training or experience in servo mechanisms is essential, knowledge of analog computer techniques and operations analysis desirable.



Discriminating prophets know that Republic offers the best in professional development, security, working and living conditions. Long Island with its beaches and parks, facilities for every type of recreational activity, nearness to major cultural centers, and with its refreshingly new communities, represents graceful living at its best in the East.

To discover more of the opportunities at Republic, send a complete technical and personal resume to:

Mr. George Hickman, Engineering Employment Manager

REPUBLIC AVIATION
FARMINGDALE, LONG ISLAND, NEW YORK

*Our professional prognosticators have a record to be proud of — development of Republic's famous Thundercraft, latest of which is the incredible F-105 Thunderchief, supersonic USAF fighter-bomber, capable of carrying atomic loads.

ELECTRONIC ENGINEERS...

become one of the first staff members of RCA's new ENGINEERING OPERATION at WHITE SANDS Proving Ground. The very nerve center of missile electronics!

RCA is new to White Sands! Qualified electronic engineers can now begin a career in a responsible position where the atmosphere crackles with the stimulation of far frontiers in missile electronics. Specific RCA assignments are in missile electronics, ground support systems, missile guidance and complex launching systems. You must, of course, have your EE, ME or physics degree, several years' electronic design experience . . . and must be familiar with one of these fields:

System and sub-system analysis
Reliability data control
Evaluation of new components
Internal instrumentation
Equipment control
Data analysis

Projects will relate to sub-systems such as:

PRECISION RADARS
DIGITAL DEVICES
ANALOG DEVICES
DATA PROCESSING EQUIPMENT
FIRE CONTROL
DATA SIMULATION

Start at an excellent salary . . . A full program of liberal benefits gives your income added security. RCA's Tuition Refund Plan will provide for advanced studies. RCA pays relocation expenses.

ARRANGE CONFIDENTIAL INTERVIEW WITH ENGINEERING MANAGEMENT

Send complete resume to:
Mr. John R. Weld
Employment Manager, Dept. V-13C
Radio Corporation of America
Camden 2, N. J.

RCA®

RADIO CORPORATION of AMERICA

DEFENSE ELECTRONIC PRODUCTS

Chrysler Transfers Personnel to ABMA

HUNTSVILLE, Ala. — Chrysler Corporation, which has been manufacturing limited quantities of the Army's Redstone short-range missile in its Detroit plants, is transferring 21 employes and their families to Huntsville, Alabama. Purpose of the move is said to bring specialized missile engineers into closer contact with the Redstone Arsenal and Army Ballistic Missile Agency here.

Local representatives of Chrysler would not comment on reports that the transfer of the group portends increased production here of the Redstone and other missiles. Heretofore, production of the Redstone missile has been equally divided between Detroit and Huntsville.

RMC Organizes Subsidiary Plant On West Coast

Rochester Manufacturing Co. of Rochester, N. Y. has set up an engineering and production subsidiary at Pasadena, Calif. to produce aircraft and missile high pressure gauges.

New firm, to be called Rochester Manufacturing Co. of California, will produce gauge equipment developed by Lindsay Engineering Co. of Pasadena. J. E. Lindsay, former research scientist at California Institute of Technology and inventor of the new gauge, will be manager of engineering for the RMC subsidiary.

A. H. Ottman, RMC president, said the west coast firm probably will be geared to assemble and store products manufactured in its three Rochester plants, including weapons fire control components.

New Missile Gear Firm Formed in Massachusetts

Geartronics Corp., new precision instrument gear firm located at 30 Nashau St., Woburn, Mass. has been formed as an outgrowth of the merger of Massachusetts Gear & Tool Co. and Gear Systems, Inc.

According to John H. Lyman, the firm's president, the consolidation will provide facilities for production of both precision and commercial gears, complete gear systems and gear research and development for industrial and military applications.

Prior to the merger, Gear Systems, Inc. played a major role in R&D activity for radar, aircraft, missile, computer and atomic energy applications. Heading research for the new firm is Prof. Earle Buckingham.

ormerly of the mechanical engineering department at Massachusetts Institute of Technology.

Martin Begins Shift into Denver Plant

The Martin Co. during February moved a starting group of 63 employes into its new Denver plant that is slated to build the *Titan* ICBM. Over the next several months, the company expects to install about 600 tools and major pieces of equipment into the facility and to vacate a temporary manufacturing plant in Denver.

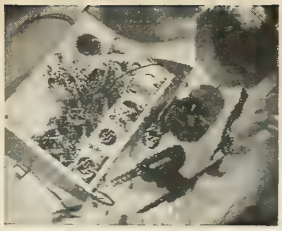
To date, Martin contracts from the Air Force on the Titan project total $385 million.

Beckman Computers Ordered For *Thor, Titan*

Two new orders for computer and data processing equipment have been announced by Beckman Instruments, Inc. for major missile programs.

Douglas Aircraft Co. has an order with the Fullerton, Calif. firm for a 200-channel, Beckman 112 transistorized data-processing system to speed research on Air Force's *Thor* intermediate range ballistic missile.

Baldwin-Lima-Hamilton Corp. also took delivery of the first of a new series of transistorized special purpose analog computers designated the Beckman 101. Baldwin-Lima-Hamilton will use a total of 10 Model 101 computers as part of the instrumentation on test stands it is developing for Martin-Denver for the *Titan* ICBM project.

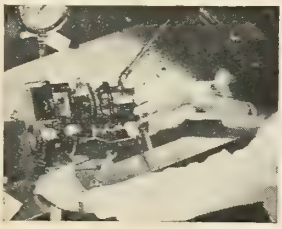


Both devices are being produced by Scientific Instruments Division of Beckman.

Bell To Expand R&D Program

Bell Aircraft Corp. is planning a $15 million expansion of its research and delevopment facilities including the construction of The Lawrence D. Bell Research Center on a 100-acre tract in Cheektowaga, N.Y.

Bell president Leston Faneuf, in a recent talk in Buffalo, said the center will include a hypersonic windtunnel and other facilities for thermal barrier research.



Expansion program at Bell also will include a new electronic computer and data processing center, a large engineering research building and a development manufacturing shop. These facilities will occupy 619,000 sq. ft.

TEST EQUIPMENT

The Test Equipment Engineer is engaged primarily in the design of specialized missile check-out equipment. As missiles push the state of the art, test equipment must exceed the missiles in precision and reliability. Automatic programing, go-no-go evaluation, and automatic data processing add up to automation in missile testing.

This engineer is evaluating his design of a precision power supply—one of the building blocks that will be system engineered into a family of versatile matched missile and sub-system test equipment. Engineers work as individuals.

HYDRAULIC DESIGN

Excellent opportunities are available for the engineer to observe the performance of his design. Here, under the watchful eyes of its designer, a hydraulic power unit is undergoing adjustment and setting prior to severe testing at simulated high altitude conditions.

Many components, which a few months ago seemed almost impossible to design, are now being tested under the severe conditions required to qualify them for flight operation—and passing with flying colors.

STEERING INTELLIGENCE

Two Steering Intelligence Engineers discuss space allotment in a new guidance component. This close association of engineers with the "flying" equipment is typical of the Steering Intelligence Section. Engineers in this section are primarily *and directly* concerned with refining the guidance equipment to steer the missile with greater accuracy, at greater ranges and with simpler and more reliable electronic equipment and, consistently, with minimizing the cost. Work is actively in progress in every principal field from microwave equipment to inertial end instruments.

Bendix

PRIME CONTRACTOR FOR TALOS MISSILE

Offers more interesting and challenging job opportunities!

If you are interested in guided missiles, you will be especially interested in Bendix. As prime contractor for the important and successful Talos Missile, the job opportunities here cover the widest possible scope, and the opportunities for advancement are practically unlimited.

Here is a compact, hard-hitting organization backed by all the resources of the nation-wide Bendix Aviation Corporation—an organization dedicated to the design and production of the finest in guided missiles.

If you can accept a challenge, want an opportunity to grow with a leader in its field, and can accept the responsibility that goes with opportunity, send for the thirty-six-page book "Your Future in Guided Missiles". It gives the complete, detailed story of the function of the various engineering groups and the many job opportunities available for you.

Just fill out the coupon. It may help you plan a successful future in the guided missile field.

Bendix Products Division—Missiles
412 L, Bendix Drive, South Bend, Indiana

Gentlemen: I would like more information concerning opportunities in guided missiles. Please send me the booklet "Your Future In Guided Missiles".

CAREER ENGINEERS ARE COMING TO BALTIMORE TO JOIN THE LEADERS AT WESTINGHOUSE-BALTIMORE

Today's electronic pioneers are reversing the maxim of Horace Greeley to "go West young man." They're coming East, but, they're going Westinghouse . . . and building their careers at Westinghouse-Baltimore. Here, the frontiers of tomorrow's electronic developments are being charted—and here, the young engineer can assure himself rapid professional growth with a company that respects and rewards its engineers. Wherever you are located—whatever school you attended—whatever your engineering experience and ability—you owe it to yourself to investigate the opportunities open to you at Westinghouse-Baltimore. Find out why so many of your fellow engineers have come to Baltimore to join the leaders in the electronics field. Write that letter today—and get the facts. You have nothing to lose—and a great future to gain.

CURRENT OPENINGS EXIST IN:

CIRCUITRY • MICROWAVES • SERVOMECHANISMS MAGNETIC AMPLIFIERS • DIGITAL COMPUTER DESIGN & APPLICATION • FIRE CONTROL SYSTEMS • OPTICS COMMUNICATIONS • PACKAGING • TRANSFORMERS ANALOG COMPUTER DESIGN • VIBRATION • RADAR DESIGN FIELD ENGINEERING • INFRARED TECHNIQUES • ANTENNAS TECHNICAL WRITING • TEST EQUIPMENT • HYDRAULICS MAGNETRON TUBE EVALUATION • METALLURGY

TO APPLY:

For a confidential interview send a resume of your education and experience to:
Dr. J. A. Medwin, Dept. 624, Westinghouse Electric Corporation, P. O. Box 746, Baltimore 3, Maryland

CAN YOU FILL THIS CAREER OPENING?

ELECTRONIC TRANSFORMER ENGINEERS—Design and development of audio, i-f and r-f coils, flea-power to 600 x 10^6 v-a, frequencies up to 1000 MC, both linear and saturable, involving problems of balance, shielding, bandwidth, insulation, heat transfer, wave shape, efficiency and regulation.

SALARY—TO $9,100.00

Columbia U is Commended By GE for Defense Efforts

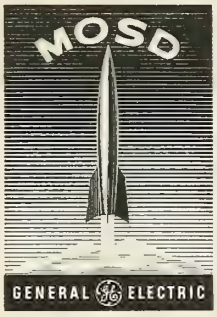
Columbia University's Electronics Research Laboratories have been commended by General Electric as a leading contributor to the nation's air defense capability. J. J. Farrell, General Manager of the G-E Heavy Military Electronic Equipment Department at Syracuse, said that certain basic computing, storage and display components used in a new ground control intercept system produced by his department for the Air Force were developed at Columbia's Research Laboratories under the initial direction of Dr. John R. Ragazzini, who is now Executive Officer of the University's Department of Electrical Engineering. Professor L. H. O'Neill, currently Director of the Electronics Research Laboratories, completed the development.

Mr. Farrell termed the development of the intercept system an outstanding example of "university-industry cooperation" aimed at the primary goal of promoting national security. Nomenclature for the overall system which includes the Columbia developed "Ragazzini Computer" is the AN/GPA-37 Radar Course Directing Group. The system is designed to receive data from long range radars, track the potential enemy aircraft and subsequently direct our interceptors to the target for the kill.

$2.4 Million Missile Awards By AMC

Largest of three new missile contracts awarded by USAF's Air Materiel Command went to Goodyear Aircraft Corp. and totaled $1,279,496 for *Matador* (TM-61B) missile guidance system facilities. GAC is prime contractor for both *Matador* guidance and ground handling equipment.

Other AMC contracts were awarded Aerojet-General Corp. ($266,882) for rocket boosters and igniters, and to Hughes Aircraft Corp. ($920,000) for *Falcon* missile facilities.



Ryan Gets New Contract For *Firebee* Drones

Ryan Aeronautical Co. has received two Air Force and one Navy contract totaling $5,350,000 to produce more than 100 additional *Firebee* jet target drones. The *Firebee* is now in use at USAF's Vincent AFB, Ariz.

Ryan officials said that other contracts expected soon will extend *Firebee* production to mid-1958. Company is also developing an advanced version of the drone for USAF to enable it to reach higher speeds and altitudes.

Continental Aviation & Engineer-

ENGINEERS & SCIENTISTS

SYMBOL OF ADVANCED THEORY AND RESEARCH IN THE GUIDED MISSILE FIELD

This General Electric department is prime contractor for "Intercontinental Ballistic Missile" and "Intermediate Range Ballistic Missile" nose cone development. Increasing emphasis on this and other guided missile programs continues to create openings on our professional staff for graduate engineers and scientists with experience in the following or related fields:

MATERIALS & PROCESSES • AERODYNAMICS • AEROPHYSICS • THERMODYNAMICS • ELECTRICAL DESIGN • STRUCTURAL DESIGN • STRESS ANALYSIS • DATA PROCESSING • SYSTEMS • SYSTEMS TEST • FIELD TEST • VIBRATION • INSTRUMENTATION • CONTROLS • ARMING AND FUZING • INERTIAL GUIDANCE • GROUND SUPPORT EQUIPMENT DESIGN

We would be pleased to receive a resume of your education and experience in order to arrange a personal interview with the manager of the appropriate technical area. Please address all correspondence to:

Mr. John Watt • Room 540-8
MISSILE & ORDNANCE SYSTEMS DEPARTMENT
GENERAL ELECTRIC
3198 Chestnut Street, Philadelphia 4, Pa.

Engineers!

The "Heart Beat" of the missile is the electronic system that directs and guides its unerring flight. The Crosley Division of AVCO Manufacturing Corporation is expanding its programs and there are top positions for Engineers in many different categories.

★ADVANCED RESEARCH ENGINEERS

★SENIOR RESEARCH ENGINEERS
Airborne Defense Systems

★PROJECT ENGINEERS
Computer & Analytical Systems
Guided Missile Programs

THERE ARE ALSO OPENINGS IN:

★GUIDED MISSILES

★COMPUTER AND ANALYTICAL SERVICES
Design and Development
Programming and Application

★GROUND RADAR

★AIR TRAFFIC CONTROL

★ANTENNA AND MICRO-WAVE EQUIPMENT

★COMMUNICATIONS
Airborne Transmitters
And Receivers

★AIRBORNE FIRE CONTROL SYSTEMS

★AIRBORNE DEFENSE SYSTEMS

★SERVO-MECHANISMS

★TRANSISTORIZED EQUIPMENT

Write us and find out where you can fit into the major programs now being started. We'll send you literature and we'll tell you about the advantages of family living in Cincinnati—the "Queen City of the West—Closest to the Heart of America." There are numerous company benefits and you will be paid generous relocation expenses.

Send resume to:
MR. NICK M. PAGAN,
Employment Manager, Dept. M

AVCO MANUFACTURING CORP.
CROSLEY DIVISION

2630 GLENDALE-MILFORD ROAD
EVENDALE, CINCINNATI 15, OHIO

ing Corp., producer of the J69 jet engine for the *Firebee*, disclosed that a Ryan XQ-2B drone has achieved an altitude of 53,500 ft. during tests at Holloman AFB, N. Mex. Drone was recovered by parachute after 97 minutes of powered flight.

Positions Available in U.S. IGY Satellite Tracking

The Astrophysical Observatory of the Smithsonian Institution, 60 Garden Street, Cambridge 38, Massachusetts, is accepting applications from scientists and technicians for positions in the Optical Satellite Tracking Program of the IGY. Qualified personnel will be assigned as observers to IGY stations in the United States, and in foreign countries for periods from one to two years. Prior experience in physics, astronomy, or electronics is mandatory and an academic degree in one of these fields is desirable.

Interested persons should write to the Associate Director, Satellite Tracking Program, at the address mentioned above.

Elgin Gets $360,000 In New Nike Contracts

Recent $360,000 contract award to Elgin National Watch Co. for safety and arming mechanisms for Nike missiles has increased by more than 200% its production in that program, the company reports.

Elgin is presently working on three contracts for the electro-mechanical fuzing device which it recently redesigned under assignment from Diamond Ordnance Fuze Laboratories.

Republic To Build New Wind Tunnel

Republic Aviation Corp. has let a $200,000 contract with Burns and Roe, Inc., New York engineering and construction firm, to design and supervise construction of a new windtunnel facility for advanced aircraft and missile testing.

Project will involve two tunnels—a transonic facility covering speed ranges from Mach 85 to 1.4, and a supersonic tunnel for testing up to Mach 4)3,000 mph).

Tunnel facility will be housed in a 72 by 82 ft. building at Republic's Farmingdale, L. I. location. Total project will run about $1 million.

Firm of Burns and Roe previously was responsible for design of ground equipment for both the Bendix *Talos* and Boeing *Bomarc* missiles as well as the Naval Aero Turbine Test Station, Trenton, N. J.

missile literature

ANALOG COMPUTERS. New booklet entitled "High-Speed Analog Computers, Key to Rapid System Development," presents question-and-answer type description of a number of computer types and their application in development of control systems for military weapons, by GPS Instrument Co., Inc.

Circle No. 107 on Subscriber Service Card

MICRO SWITCHES. New 32-page catalog available from Micro Switch, a Division of Minneapolis-Honeywell Regulator Co. describes more than 140 switches, switch actuators and terminal enclosures it produces for airborne applications.

Circle No. 108 on Subscriber Service Card

SERVO MOTORS. Bulletin No. 385 issued by Norden-Ketay Corp. contains complete data on its standard and custom servo motors.

Circle No. 109 on Subscriber Service Card

BALANCING MACHINE. A 16-page booklet published by Stewart-Warner Corp. gives details on its electronic dynamic balancing equipment used for aircraft and missile jet engine rotors, impellers, gears and flywheels, etc.

Circle No. 110 on Subscriber Service Card

D-C MOTORS. Fractional Horsepower d-c motors built to Spec. MIL-M-8609 are illustrated in 8-page booklet by Lundy Manufacturing Corp.

Circle No. 111 on Subscriber Service Card

NICAD BATTERIES. Nickel cadmium batteries for aircraft and missile use are described in 8-page technical report prepared by Nickel Cadmium Battery Corp.

Circle No. 112 on Subscriber Service Card

SHOCK TUBES. Avco Manufacturing Corp. has published a 10-page brochure describing new services it offers in the design and manufacture of special shock tubes for aircraft and missile research. To date Avco has developed units capable of simulated speeds of Mach 25 at altitudes exceeding 100,000 ft.

Circle No. 100 on Subscriber Service Card

ROCKET FACILITIES. Four-page brochure describing facilities and past activities in solid-propellant rocket development is available from Grand Central Rocket Co.

Circle No. 101 on Subscriber Service Card

PROPELLANT-POWERED CUTTERS. New leaflet distributed by Propellex Chemical Corp. announced availability of its electrically-initiated, propellant-powered cutters for parachute risers and reefing cords.

Circle No. 102 on Subscriber Service Card

MINIATURE BEARINGS. New 16-page catalog lists RMB miniature ball and roller bearings produced in Switzerland and marketed in U.S. by Landis & Gyr, Inc.

Circle No. 103 on Subscriber Service Card

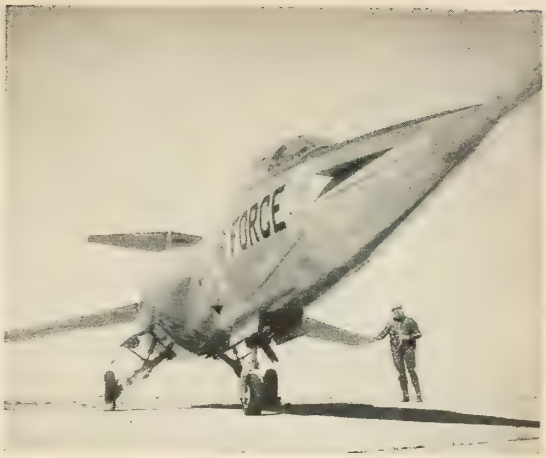
METALLURGICAL TESTS. Complete scope of metallurgical testing services available from Crippen & Erlich Laboratories, Inc., subsidiary of Foster D. Snell, Inc. are described in four page folder. Price list included.

Circle No. 104 on Subscriber Service Card

SILICONE REPORT. Laboratory report on its new fluorinated silicone compound for aircraft and missile fuel systems is available from Acushnet Process Co.

Circle No. 105 on Subscriber Service Card

MAGNESIUM/TITANIUM DATA. New 44-page booklet published by Brooks & Perkins, Inc. describes in detail the physical and mechanical properties of magnesium and titanium, including forming, welding, machining, heat treatment and stress relief characteristics.



Circle No. 106 on Subscriber Service Card

INFRARED SYSTEMS. New 8-page brochure issued by Servo Corporation of America described company's infrared applications and research activities in producing and delivering some 21 such weapons systems to date.

Circle No. 120 on Subscriber Service Card

LOW TEMPERATURE APPARATUS. Hofman Laboratories, Inc. has published a 16-page catalog illustrating low temperature equipment it produces, including capacity and performance data on specific liquid oxygen and nitrogen handling units.

Circle No. 121 on Subscriber Service Card

Throws out electron tubes... keeps chopper

Today's aviation electronic standards are often tough to meet. Demands for extreme miniaturization are coming hard on the heels of new reliability and performance standards.

We've heard of one well-known manufacturer, for example, who has gradually eliminated all electron tubes and most other conventional electronic parts from his jet engine control system.

But it's significant that this manufacturer is still using the Bristol Syncroverter® Switch to convert servo signals from d-c to a-c.

The reason? There's no equivalent that comes up to the Syncroverter Switch's performance. *Long life* and *Immunity to Severe Shock* and *Vibration* are outstanding characteristics of the Syncroverter Chopper.

During vibration over the range of 5 cps to 2000 cps and up to 30G, the effect on output waveform is negligible.

Write today for data on this outstanding chopper for your critical signal conversion problems. The Bristol Company, 173 Bristol Road, Waterbury 20, Connecticut.

Bristol Syncroverter Switch. Covered by patents.

6.73

TYPICAL OPERATION

Driving frequency range:	0-2000 cps (400 cps used for these characteristics)
Coil voltage:	6.3V sine, square, pulse wave
Coil current:	55 milliamperes
Coil resistance:	85 ohms
***Phase lag:**	55° ± 10°
***Dissymmetry:**	Less than 4%
***Switching time:**	15° ± 5°
Temperature:	—55°C to 100°C
Operating position:	Any
Mounting:	Flange or plug-in—fits 7-pin miniature socket

*These characteristics based on sine-wave excitation.

TAKE ADVANTAGE OF MISSILES AND ROCKETS NEW SUBSCRIBER SERVICE

DO YOU WANT MORE INFORMATION ABOUT NEW MISSILE AND ROCKET PRODUCTS?

All you do is circle the number on the card to the right that corresponds to the number following the items mentioned inside this magazine.

DO YOU WANT MORE DETAILS ABOUT THE ADVERTISED PRODUCTS OR SERVICES IN MISSILES AND ROCKETS?

These data are yours for the asking. Just circle off the proper number indicated below or next to the particular advertisement you want to know more about. Your request for information will be forwarded promptly to the companies concerned.

Coming Next Month

the Revised

SPRING-SUMMER 1957 EDITION

of the

WORLD AVIATION DIRECTORY

Guided missile expenditures are jumping from $1.1 billion last year to an estimated $1.5 billion this year and over $2 billion (estimated) for 1958. In aviation manufacturing third quarter 1956 figures show a $18 billion backlog—up $4.5 billion over the same period in 1955. In air transportation, total revenue of the U.S. scheduled airlines shows a 14% INCREASE in 1956 over 1955.

With missile spending still rising and the entire aviation industry still very much in a boom, you'll be needing more complete information than ever before for buying—spending—research and reference purposes. Next month the complete WORLD AVIATION DIRECTORY comes off press.

This completely revised 1957 WORLD AVIATION DIRECTORY in its new Spring-Summer Edition packs in all names and job titles of over 21,000 key people in the industry plus listings of more than 6,500 companies. Here, in one handy volume of over 1,000 pages are 27,000 names of executives, companies, their products/services; plus names of organizations, all classified and cross-indexed for fast reference. Included is a big valuable special BUYERS' GUIDE.

helping guide the NIKE

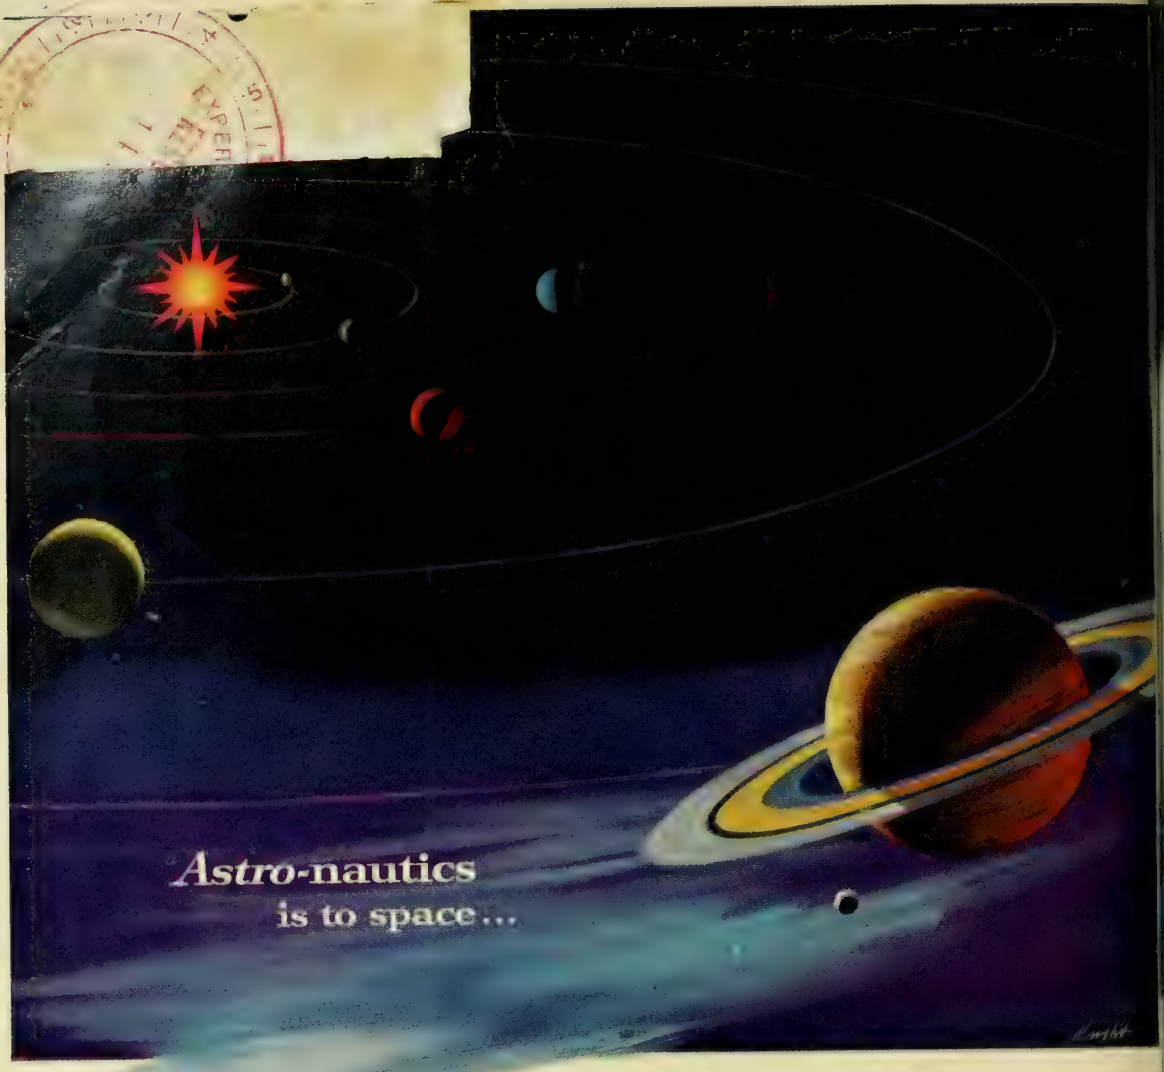
To intercept and destroy, Nike flies higher and faster than *any* aircraft. The electronic brain of the Nike outmaneuvers the fastest fighter. To keep the Western Electric Control Unit thinking clearly, an Eastern Pressurization Unit and Aircraft Pumps control the operating pressures of the electronic systems.

Nike is the first missile to enter full combat-ready service. As others are developed to fly higher, faster, and deadlier, Eastern accepts the critical task of helping to break through the barrier of the unknown and untried. With *creative engineering* and the facilities to test and to manufacture new-idea equipment without delay, Eastern serves those who put the ting in national air defense.

When your design-application calls for the control of temperature or pressure in electronic installations, Eastern liquid-cooling units and pressurization equipment can help you meet government requirements.

Eastern hydraulic power units are extremely compact and provide extremely accurate control under severe operating conditions in servos and similar applications.

Eastern solicits inquiries involving your projects. We offer our creative engineering service for new designs, as well as an extensive line of existing units and adaptations.



Aviation Catalog 340, on request.

This Issue:

US AIR FORCE LONG-RANGE MISSILE DEVELOPMENT

"MIL SPECS"

The industry has long established the Mil Spec as a measuring stick of performance and quality. At Narmco, we too feel at home with Mil Specs.

But the manufacturer of airframes and missiles searches for and insists upon properties and performance values which go beyond Mil Specs ...to the limits of present knowledge. Narmco offers effective support to such programs.

There are very good reasons why this is so. Narmco's selected teams in research, development, application, production, and quality control were "born and raised" on the tough ones and ultimate goal concepts! More and more Narmco products are being used every day in the airframe and missile industry... *doing jobs that metals alone cannot do!*

These Narmco products qualify and exceed Mil Specs: Conolon 506, MIL-R-9299; Conolon 501, MIL-P-8013; Metlbond 4021 system, MIL-A-5090B; and Metlbond 302 has pending qualification under MIL-A-8431. In addition, a wide range of Narmco products meets rigid "customer specifications" established by nearly a score of the leading airframe and missile manufacturers.

NARMCO

PIONEERING THROUGH RESEARCH

Narmco technical field representatives throughout the United States and Canada can assist in solving your structural design problems quickly, efficiently and economically. For immediate assistance, write, wire or phone...

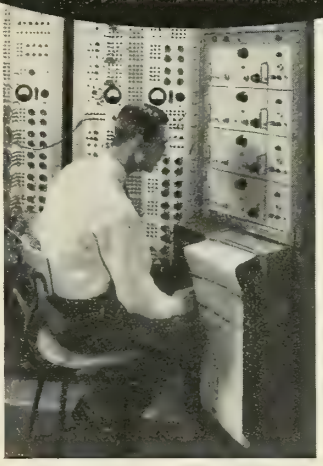
TECHNIQUES and DEVELOPMENTS
in oscillographic recording

FROM
SANBORN

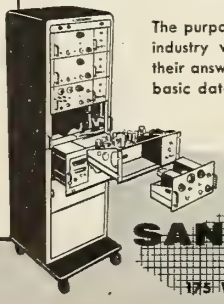
PHASE SENSITIVE DEMODULATOR PREAMPLIFIER PROVIDES A DC VOLTAGE PROPORTIONAL TO AN INPHASE COMPONENT OF AN AC VOLTAGE WITH RESPECT TO A REFERENCE.

THE measurement of the amplitude of an AC voltage component is often necessary in performance studies of servo systems or of suppressed carrier signals over the carrier frequency range from 60 to 10,000 cps. In such cases the demodulator responds to inphase signals and rejects quadrature signals.



A circuit with these characteristics for use in an oscillographic recording system can be seen in the Model 150-1200 Servo Monitor (Demodulator) Preamplifier. It was developed by Sanborn as one of twelve interchangeable, plug-in front ends for "150" Series equipment, to be used with the appropriate Driver Amplifier-Power unit in any channel of a "150" system. Elements comprising the circuit from input to output, include: compensated stepped attenuator and cathode follower input circuit, phase inverter, push-pull mixer and demodulator stages, differential DC output amplifier and low pass filter. In addition, the chassis contains a VTVM to facilitate accurate adjustment of the reference voltage, and an overload indicator which lights a warning lamp when excessive quadrature voltages exist.

Adaptability to a fairly wide variety of applications is accomplished through broad input voltage, reference voltage and frequency ranges. In order, these are 50 mv to 50 v (for full scale 5 cm deflection), 10 v to 125 v; 60 cps to 10kc. Rise time with low frequency plug-in demodulation filter is 0.1 seconds; with high frequency filter, 0.01 seconds. Quadrature rejection is better than 100.1; for carrier frequencies up to 5000 cycles.



Two representative uses of the Servo Monitor Preamplifier are in the design and adjustment of servo systems, and with instruments used in the design, development or adjustment of other apparatus. The first is illustrated by use of the Preamplifier and associated equipment in the recording of the output shaft amplitude and driving frequency of an AC positional servo; the second by recordings made with a similar setup of the difference between output signals from a gyroscopically-controlled stabilizing device and the "pitch" and "roll" signals generated by a "Scorsby Table" used for testing the device under dynamic conditions.

For a detailed discussion of the principles and design considerations involved in the Servo Monitor Preamplifier, refer to the February, 1955 issue of the Sanborn RIGHT ANGLE, for Dr. Arthur Miller's article on "Measurements with the Servo Monitor Preamplifier."

BASIC FACTORS IN SELECTING OSCILLOGRAPHIC RECORDING EQUIPMENT

WHEN considering any oscillographic system or equipment for your application, three useful "yardsticks" to apply are (1) the recording method, (2) equipment adaptability, and (3) variety of equipment available. Here are the answers to the three, as they apply to Sanborn systems. In the record, rectangular coordinates accurately correlate multiple traces, simplify interpretation and eliminate errors. Permanent traces, produced by a hot ribbon stylus without ink, provide sharp peaks and notches, and clearly reveal all signal changes. One percent linearity results from current feedback driver amplifiers and high torque galvanometers of new design; maximum error is ¼ mm in middle 4 cm of chart, ½ mm across entire chart. From the standpoints of "adaptability" and "variety", Sanborn "150" equipment offers the versatility of 13 different plug-in front ends for any basic system . . . the choice of one- to eight-channel systems . . . the variety of nine chart speeds, timing and coding controls, console or individual unit packaging . . . availability of equipment as either complete systems or individual amplifier or recorder units.

The purpose of the foregoing information is to better acquaint industry with typical oscillographic recording problems and their answers, design considerations in Sanborn equipment, and basic data on what Sanborn makes and how it is being used.

Technical literature and engineering assistance on specific problems are always available from our engineering department.

keeping an idea locked between your ears?

If it deals with guided missiles, you'll find Firestone has the key to unlock it—and open the door to a happier future for you. Firestone's creative climate and tangible rewards keep that door open to a steady flow of achievement and growth.

Since the turn of the century, Firestone men with ideas between their ears have pioneered in research, development and manufacture. Currently, they're carrying forward the vital "Corporal" program for the Army. Even more exciting, our facilities in both Los Angeles and Monterey are forging new links in the chain of progress.

Right now, we need more ME's with ideas for the unlocking ... ideas that have to do with:

Structures Airframe
Dynamics
Stress Analysis
Materials & Process
Hydraulics
Propulsion System Design

A man at Firestone can help you make the most of that idea—and your future. Write him today!

The Weapon Comes First

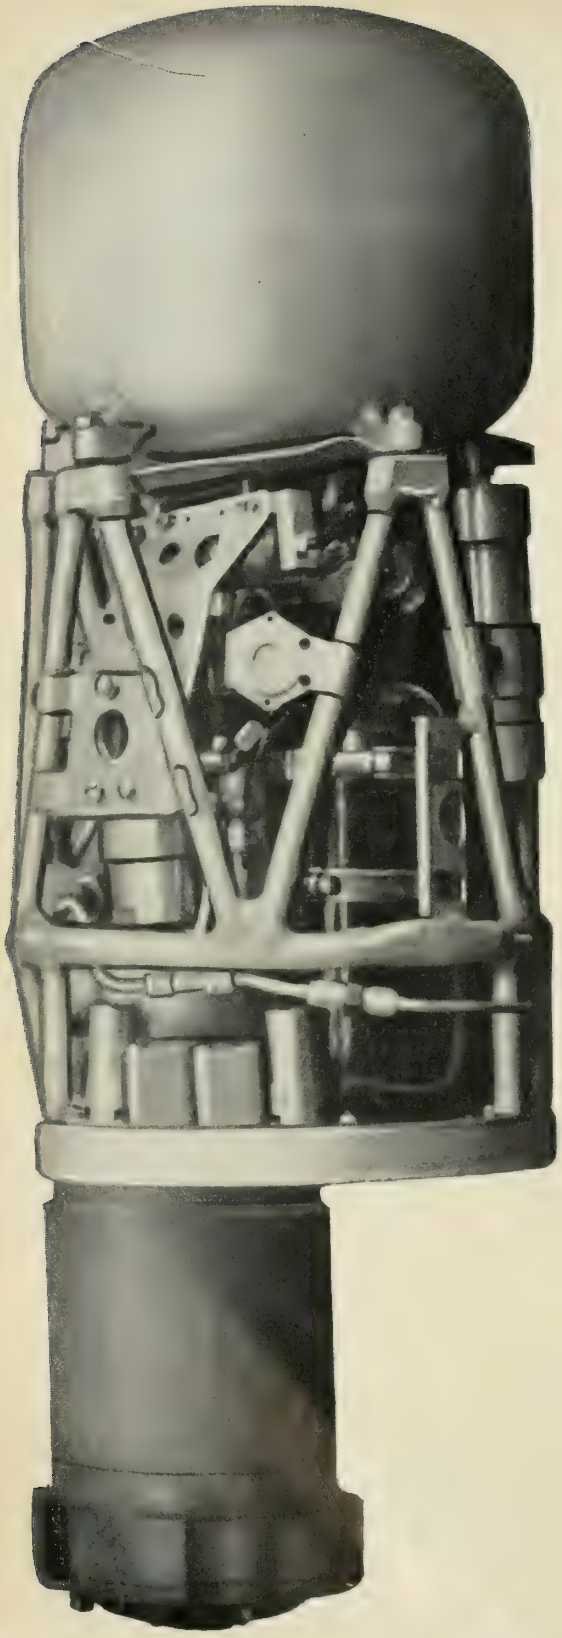
America's long-range ballistic missile effort is not an academic exercise in a vacuum. It is not a casual endeavor that can long endure the deprivations and distractions of roles and missions disputes, political jockeying or ulterior bickering of any kind. Who intones the countdown may have a bearing on this or that Service's prestige and future and is important to tomorrow's battlefield tactics and strategy. But, the overriding order of business is to see that such a countdown ability exists in time.

The men of the Kremlin will not hesitate to resort to sudden, devastating nuclear assault if they are once certain that the capability for immediate massive retaliation is even momentarily lost to the West. Meanwhile, reports of Soviet successes in ballistic missile development cannot be assumed to have other than some basis in fact.

Thus, the current *Jupiter* and *Thor* schedule of test firings plus reports that *Atlas* is moving to its launching pad is a source of hope rather than terror.

The proximate success of this unprecedented technological undertaking reemphasizes this country's inability to admit the impossible; and sets enviable standards for a young, precocious industry.

The contributions of the men behind these programs cannot be reckoned by the salaries they are paid or the fame they gain. It is unfortunate that the only means the Free World has to preclude war is to maintain the ability to win a war. But we know of no alternative. To this these men are dedicated.



In this sense, it is only logical that at this level of prime importance — research and development — secondary considerations now be set aside; that Army and Air Force missile men shake hands, rather than hurl epithets.

If current roles and missions assignments are incorrect, this will soon be apparent. Now, it's more important to get a weapon in being than to fight over who uses it.

It is certain that the result of the many approaches will be better than that of any one. It is also certain that though this is a tool for war, the peaceful future of its progeny lies in the infinite reaches of outer space.

This is the beginning of the second era of man. If it were without its quarrels, it would not be human.

ROBERT H. WOOD

Extra Muscle for Missiles

A DEPENDABLE SOURCE OF AUXILIARY POWER

Pioneers in the development of reliable, lightweight, self-contained monofuel auxiliary power systems for guided missiles and piloted high performance aircraft, Kidde now offers its combined engineering talents and precision manufacturing resources to firms interested in advanced applications of auxiliary power systems.

At present, Kidde has available turbine-driven units with horsepower of up to 200. These high speed units are designed to supply accurately regulated power at mean altitudes of 40,000 feet and up. However, they may easily be made environment-free, permitting airframe builders extremely wide latitude in systems design.

As a part of its power system development program, Kidde has gained wide experience with many monopropellants. These include ethylene oxide, hydrazine, hydrogen peroxide and propyl nitrate.

Whatever your present or future auxiliary power requirements, Kidde is ready to develop, test and manufacture equipment which will meet your exact specifications. For full information, write Kidde today.

Honeywell Aero's HIG-6, one of the most precise gyros ever designed, is now in quantity production. With a drift rate of less than 0.1 degree per hour, it represents the furthest advance yet made in a production, inertial-type gyro. The HIG-6 is applicable to both full inertial and aided-inertial systems. Standard models of this gyro can be delivered in as little as three months' time.

AERONAUTICAL DIVISION, MINNEAPOLIS-HONEYWELL

MILITARY FIELD SERVICE

an integral part of Burroughs responsibility for computation in SAGE

For its vital computation phase of SAGE (continental air defense system) Burroughs responsibility to the Air Force begins with research . . . extends through engineering, development, production, testing, and installation . . . and includes essential field training, service and engineering.

Resident teams of Burroughs Military Field servicemen are assigned to each SAGE site. These specialists install and continually test each computer, executing field service functions through intimate knowledge of the equipment.

Already, scores of Burroughs specialists are on Military Field Service duty at home and abroad, wherever they are required to service complicated equipment.

This is another demonstration of Burroughs *complete* systems responsibility for numerous Armed Forces projects embracing instrumentation, control systems, communications, electronic computers, data processing.

In the areas of our proved capabilities, we welcome further inquiries. Call, write or wire Defense Contract Organization, Burroughs Corporation, Detroit 32, Michigan.

Budd

Explorers of the Unknown in Metals—Wants High Level

ENGINEERS

To Blaze New Trails in the Development & Perfection of Metals Suited for Use in

- **AIRCRAFT STRUCTURES**
- **MISSILE STRUCTURES**
- **NUCLEAR PROPULSION & REACTOR ELEMENTS**
- **NUCLEAR PROPULSION STRUCTURES**

Another *FIRST* for Budd!

Here in our Aircraft Research and Nuclear Propulsion Laboratories — an outgrowth of the research activity which produced such great industrial engineering FIRSTS as the all steel automobile body, stainless steel railway cars and the all steel two-engine planes — BUDD has just reached another milestone in its exploratory achievements: a solution to the practical and efficient manufacture of structures for aircraft and missiles subject to aerodynamic heating has been found!

With a manufacturing background of nearly half a century and more than 20,000 people on its payroll, The BUDD Company is the established leader in its field. To competent Technical and Scientific Personnel seeking an association with a company offering established employment stability and salaries commensurate with ability, there *truly* is no finer place to work.

If you are interested in an association in a high level research environment, in one of our plants in the East, please fill in the Ready-Reference Card below and send to THE PLANT OF YOUR CHOICE, today, along with a complete resume of your educational and work background.

THERMAL CONDITIONING OF ROCKETS AND GUIDED MISSILES

HEATING OPTICAL, ELECTRONIC, OR HYDRAULIC AIRBORNE EQUIPMENT

WHERE CAN YOU USE G-E SPECIALTY HEATING EQUIPMENT?

Whenever your equipment requires thermal conditioning, General Electric specialty heating equipment can help.

G.E. has had extensive design and manufacturing experience in providing controlled heating for a wide variety of applications. These applications range from giant guided missile blankets to tiny one-inch-long accelerometer heaters. Problems of intricate shape, large or small size, unusual environmental conditions, and amount of heat required have all been solved.

LET US ANALYSE YOUR HEATING PROBLEM; a General Electric specialty heating expert is available and a prompt answer is assured.

FOR MORE INFORMATION contact your General Electric Aviation and Defense Industries Sales Office or send coupon.

General Electric Company
Section KK 220-10A, Schenectady 5, N. Y.

letters

Speaking of Lintz Basalt Why Not a Gravity Article?

To the editor:

Lintz Basalt in your February '57 Missile Miscellany is very interesting and an article on the current "Anti-Gravity" research projects would be an ideal follow-on.

With more than five major companies working on these projects for the past year, some of the outstanding progress could be reported.

J. E. Surratt, Jr.,
Vice-President,
Society of Aeronautical Weight Engineers, Inc.
Greenville, Texas.

As soon as we have collected sufficient evidence of specific work and proposals for such an article to be of real use to our readers, we plan to publish such a rundown. So much of a misleading, sensational nature has been published on this subject recently, we are proceeding very cautiously.—Ed.

To the editor:

I was quite astounded by the item in the Missile Miscellany column to the effect that the Silicate, Lintz Basalt, will not accelerate at 980 cm/sec. Since this is contradictory to all known physical laws if the deviation is within the limits of experimental error, I feel compelled to pursue the matter. As a graduate physicist actively engaged in the missile field, I follow your magazine closely and if past experience is any criterion I must concede that there could be some substance in this article.

James L. Morgan
C & M Enterprises
Box 512
Pacific Palisades, Calif.

To the editor:

In the February issue you published some information in your column "Missile Miscellany" which to me was strange and important. It concerned a mineral which you call "Lintz Basalt."

You specify that it gave spontaneously more heat than uranium and also that it would not accelerate at 980 cm/seg^2 in free fall.

I have spent two days at our library looking thru all our abstracts, including government information and have not yet found anything related to this "silicate." I would appreciate very much if you could tell me from what source you got that information.

J. Davila-Aponte
Physics Department
Universidad de Puerto Rico
Rio Piedras, Puerto Rico

To the editor:

This is with reference to the "Lintz Basalt." Two months before he died in 1929, Dr. C. F. Brush mentioned that he had found similar anomalies on other silicates, and other compounds of elements of high atomic weight, such as barium, lead, bismuth, and that he was in the process of correlating their impairment in falling velocity with their persistent generation of heat.

For 20 years he had been conducting experiments, with the greatest accuracy, to detect anomalies of different substances in their response to gravity, such as the ones you mentioned for the Lintz Basalt, and the zinc and bismuth pendulums.

Utilizing another test equipment to minimize the possibility of experimental error, the National Bureau of Standards conducted again some of Dr. Brush's calorimetric experiments. The results were substantially the same, leaving in their wake a big question mark.

During the last 25 years, has anyone probed beyond?

Jacques Cornillon
P.O. Box 137
Point Pleasant, Pennsylvania

That's a good question, M. Cornillon, one to which m/r, too, would like an answer—Ed.

To the editor:

In your February issue you published a notice on "Lintz Basalt" which develops heat permanently and is accelerated less than all other material.

I would appreciate it very much if you could advise me what Lintz Basalt is; I cannot find it anywhere. Furthermore if you could give me your source where I could find more about that phenomenon.

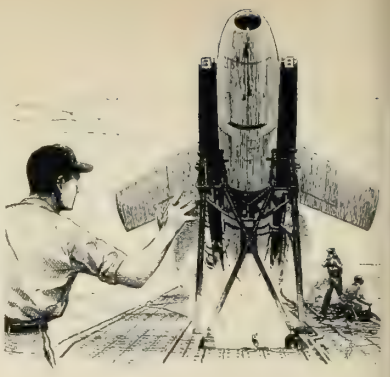
Dr. Curt Borchardt
19 Gormley Ave.
Toronto, Canada

More References On Lintz Basalt

To the editor:

Reference your letter of 26 February 1957 concerning Lintz basalt.

Thank you for the information on the reference you gave me, but nowhere in Mr. Brush's paper do I find anything concerning the acceleration of this basalt in free fall. Since this is the olive in the martini, so to speak, may I trouble you again for a reference concerning this portion of the statement?



Furthermore, in the March issue of m/r you mention NBS confirmation of his work. May I have the number of the report?

Finally, along with no doubt many other requests, may I have the reference on the zinc and bismuth plumb bobs.

You have managed to stir up a fair sized storm of controversy with your conversation pieces.

Leslie M. Bagnall
5840 Coleman St.
Ft. Worth 14, Texas

You're so right. The reference given on page 10 (The Proceedings of the American Philosophical Society, Vol. 65, April 23, 1926, a paper by Brush) of the March m/r concerns only the constant generation of heat in Lintz Basalt. References to retarded free-fall are given in Vol. 206, No. 1232—II, page 143, of the Journal of the Franklin Institute, "Some Experimental Evidence Supporting the Kinetic Theory of Gravitation," by Charles F. Brush, M.E., M.S., Ph.D., D.Sc., Eng.D., LL.D. Brush's observation of the constant generation of heat in

FOUR IMMEDIATE OPENINGS FOR ENGINEERS

★

Structural Test Engineer. To handle component structural tests (static and fatigue) under various environmental conditions — elevated temperatures, particularly. Experience in this field desired, but not essential.

★

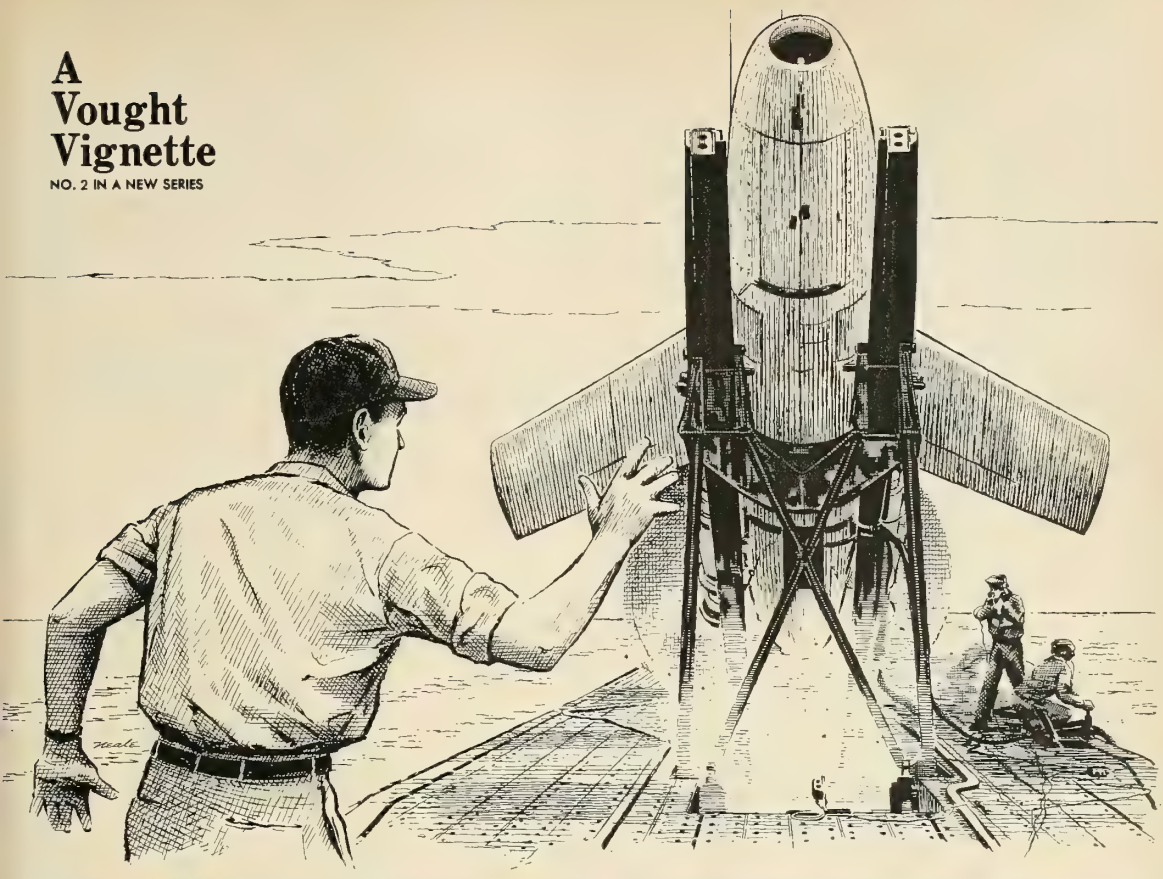
Electronics Liaison Engineer. To provide engineering assistance to manufacturing and laboratory units on electronic assemblies. Degree in mechanical or electrical engineering required.

★

Senior Structures Loads Engineer. To determine air and ground loads and airframe temperature distributions; to analyze aircraft performance relative to shipboard operation; to determine repeated load criteria of aircraft components. Requires degree in engineering, applied mathematics, or physics, plus three or more years experience in aircraft loads, applied mathematics, or applied mechanics.

★

Statistical Analyst. To determine system reliability from component failure rates. Requires knowledge of statistics and probability and a degree in statistics, mathematics, or in a related field.



To arrange for a personal interview, or for a prompt report on these openings, write to:

Mr. J. W. Larson, Asst. Chief Engineer
Dept. MR-3

CHANCE VOUGHT AIRCRAFT

A Vought Vignette

NO. 2 IN A NEW SERIES

The Missile Engineer with undersea legs

Jack Welch felt honored when he was tossed, fully clothed, into the Navy's sub harbor at Port Hueneme, California. In their own rugged way, submariners were extending him their thanks. He'd been a big help in the introduction of Chance Vought's Regulus I missile to the Navy's Undersea Fleet.

Months before his ceremonial splash, Jack had accompanied the Regulus aboard the submarines *Tunny* and *Barbero* as a representative of Vought's Missile Operations Engineering Group. A veteran of the Regulus flight test program and a collaborator on the conversion of the subs to missile carriers, Jack brought knowledge the Navy welcomed. Likewise, the Navy crews were to share with Jack some equally valuable experience.

Jack, with the submarines *Tunny* and *Barbero,* cruised the East and West Coasts, performed over 200 dives, and once prowled far west of Hawaii. The missile man helped the undersea crews complete initial checkouts of Regulus support equipment — culminating in the first missile launch ever made from a submarine. Then they went about solving environmental and supply problems that arose during tests. Jack added to his mechanical engineering experience a valuable store of electrical, weapon systems and Navy knowledge.

Back in home port, on the *Tunny's* quarter-deck, with a full crew assembled, submarine officers reviewed Jack's contributions. He'd gone beyond his duty as a technical advisor, they concluded. He'd become an expert submariner as well. In fact, he'd qualified for the Silent Service's Gold Dolphin insignia . . . and all hands would proceed at once with the traditional initiation. That's when Jack took his plunge.

Today, Jack divides his time between Chance Vought and a half-dozen Navy shipyards. His job is to see that current missile and ship design is meeting the missile needs of the Fleet. Problems are many, but Jack maintains there's a solution for each. "That's a lesson I learned from the submarine forces," he said. "They gave me a real indoctrination in a can-do attitude under actual operating conditions."

At Chance Vought the missile engineer belongs to a team that already has experienced every conceivable missile problem, from development to operational readiness. Here, current assignments range from theoretical work to the introduction of complete missile systems to the Fleet.

CHANCE VOUGHT AIRCRAFT
INCORPORATED DALLAS, TEXAS

ANALYTICAL ENGINEERS

At Hawthorne, in Southern California, Northrop Aircraft has a continuing need for experienced engineers seeking new opportunities. There are attractive positions open in the following fields: Aerodynamics, Dynamics, Thermodynamics, Stress, Loads, Performance Analysis.

In Northrop's superbly equipped multi-million-dollar engineering and science center, now nearing completion, you will be given constantly fresh and challenging assignments. Present programs include Northrop's new supersonic trainer airplane, the Snark SM-62 intercontinental guided missile, plus advanced aircraft and missile projects yet to be revealed.

You'll be associated with a high-calibre engineering team that has established an outstanding record in aeronautical design and development. Your initiative and ideas will be recognized, encouraged and rewarded, for at Northrop Aircraft the progress of personnel is as important as the progress of projects.

Besides attractive remuneration, you will enjoy other benefits unexcelled in the entire industry—retirement plans, health and life insurance, college educational reimbursement plan, regular vacations plus extra year-end vacations with pay. Easily-reached mountain, desert and beach resorts in sunny Southern California offer year 'round attractions for you and your family.

You will find the career opportunity you are seeking at Northrop, pioneer in the design and production of all weather and pilotless aircraft. If you qualify for one of these attractive positions, contact the Manager of Engineering Industrial Relations, Northrop Aircraft, Inc., ORegon 8-9111, Extension 1893, or write to: 1015 East Broadway, Department 4600- L, Hawthorne, California.

letters

various materials was confirmed by E. A. Harrington of the National Bureau of Standards. The only report of his work on this subject m/r has so far found appears in the Proceedings of the American Philosophical Society, 1933.

It is entitled: "Further Experimentation on the Constant Generation of Heat in Certain Silicates." To m/r's knowledge nobody has attempted to duplicate Brush's observations of retarded fall.M/r would like to note that it is not attempting to promote Brush's "Kinetic Theory of Gravitation," but merely wonders about the possible significance of some of the experimental evidence he produced to support his theory, which—at first glance—seems to have some bearing on the basic assumption of the equivalence of gravitic and inertial mass.—Ed.

More On Red Rockets

To the editor:

When I saw on p. 43 of your February issue a picture of a Russian missile which "ascended to great altitude" in the 1930's, I immediately recollected a news item in an old *Bulletin* of the American Interplanetary Society (15, 1, Jan. 1932) which I quote:

SOVIET ENGINEERS CONSTRUCTING TWO ROCKETS

A dispatch to the New York Times from Moscow indicates that research engineers of the Leningrad Oseaviakhim are constructing two rockets . . . one . . . is planned to be shot to an altitude of thirty miles by means of powerful discharges; the other (is to be used for) carrying two passengers to a height of ten miles into the stratosphere. Both rockets will be cigar-shaped, constructed of light alloys and steel welded together . . . descent is to be made by parachute. A communication from Professor Rynin of Leningrad . . . states that a group of rocket experiments (sic) is now active in Soviet Russia . . . headquarters at Moscow . . . group consists of about 200 engineers and scientists.

Another news item (Astronautics 31, 7, June 1935) records:

"Dispatches from Moscow announce that a Soviet stratosphere committee has ordered the construction of a rocket capable of attaining a velocity of 2,200 feet a second and a possible altitude of 34 miles . . . It is also reported that plans are being studied for a larger rocket designed to ascend several hundred miles.

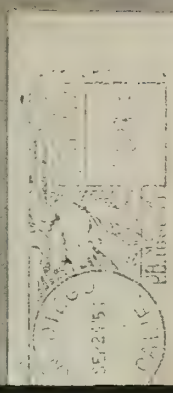
I wonder what the connections may be between these various reports?

Frederick I. Ordway, III,
General Astronautics Corp.
P. O. Box 26, Oyster Bay, N. Y.

Wants More on Drafting In Missile Industry

To the editor:

I consider m/r an excellent aid to the American missile industry. Thank you for the many interesting articles contained within its pages.



May I ask that you consider the addition of a new department, under the suggested title "Drafting in the Missile Industry"? In my opinion this would not only be helpful but, would add greatly to your list of subscribers by offering

Attention: Mr. L. Avnet, President

Gentlemen:

In the past year, we here at Convair have devoted a great deal of attention to the performance of your company. We are very pleased to report that your performance has been excellent. The splendid cooperation and service extended to Convair in all your negotiations, by your Top Management Sales Personnel, is highly commendable.

Our normal production flow and scheduled delivery of airplanes is directly contingent upon our suppliers' promise to perform to his committed shipping schedules. You have not only maintained and fulfilled these promises, but have, on many occasions, accelerated your deliveries at our request. This letter is to express our sincere appreciation for your many extraordinary efforts and the fine business relationship we have enjoyed.

Very truly yours,

What a source of supply! Resident Govt. source inspection on the premises!

breaking the barriers
with Utica Vacuum Metals

Now that supersonic flight has become routine, today's challenge lies in developing *metals* and *means* of cracking the thermal barrier.

The metals problem has already been partially solved by superalloys produced through Vacuum Melting. This process, as developed by Utica, has yielded such super refractory alloys as Udimet 500—a clean, pure alloy combining unsurpassed stress-rupture life with superior high tensile strength in the 1200° F to 1800° F range. *At 1600° F, Udimet 500 has a tensile strength of over 100,000 PSI.*

In addition to the development of new and superalloys, Utica specializes in upgrading the quality of existing alloys.

VACUUM MELTING
provides these properties

- High temperature corrosion resistance
- Increased ductility
- Extreme cleanliness
- Precise chemical control
- Longer stress-rupture life
- Increased tensile strength
- Better fatigue resistance
- Greater yield strength
- Greater impact resistance
- Greater creep properties

UTICA METALS DIVISION OF KELSEY-HAYES

UTICA DROP FORGE & TOOL DIVISION — U-MET ALLOYS — KELSEY-HAYES CO., UTICA 4, NEW YORK

information readily assimilated by all in the profession.

Further I feel that it is a point of great urgency to have a source of information from which the missile industry can develop standards, similar in organization to those of the aircraft and automotive industries.

William Brown
Design Draftsman
Utica-Bend Corp.

Wants More m/r's

To the editor:

Congratulations on your issue on Russian rockets and missiles! This has really shaken up several people that I know.

I would like to subscribe to three subscriptions to your magazine, and would like to get a set of back copies for our library.

H. J. Rand
Rand Development Corporation
12720 Lake Shore Blvd.
Cleveland 8, Ohio

Space Suit Swiped

To the editor:

I know you would like me to draw your attention to the anonymous boost I've been given from behind the Iron Curtain in the space-man illustration on page 74 of MISSILES & ROCKETS, February issue. The space man depicted in the photo of Waldislaw Geisler & Professor Satabun has been copied direct from my illustration for Martin Caidin's book "Worlds in Space."

Fred L. Wolff.
107 Michigan Avenue
Kenilworth, New Jersey

How About Sublimation?

To the editor:

Have you published anything in your magazine on the subject of evaporative cooling in the sense that a missile or rocket may be coated with a metal such as cadmium or mecury for the purpose of melting off during flight through the atmosphere upon the creation of heat through friction at supersonic speeds?

K. Ross,
Ross & Ross,
Springfield 3, Mass.

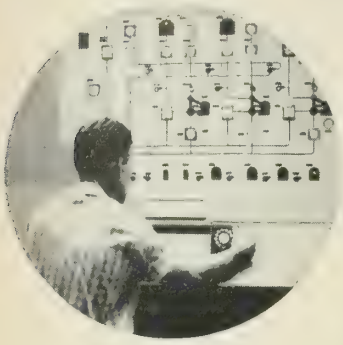
This general subject has been treated at various times in m/r. Note Henry P. Steier's report "New Telemetry Era for ICBM—Space Flight" in this issue. Aerophysics in the January issue mentions plastics in this connection.—Ed.

To Power a Satellite

To the editor:

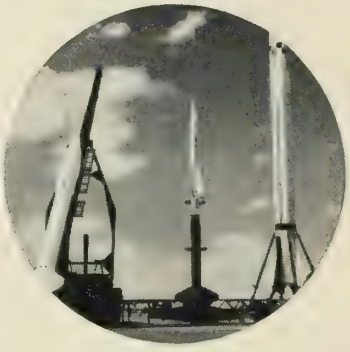
. . . With the advent of the solar battery, the problem of power supplies for space vehicles has become less acute. However, for special applications, it is possible that there might be need for a radioactive battery of a type not mentioned in the article, "Power Sources for Space Flight" in the Dec. m/r.

An electrical power supply consists of a means of producing a current of electrons, or more basically, a means of separating positive and negative charges and directing the return flow of electrons through an external load. A radioactive Beta-emitting isotope represents an elemental charge separator. The Beta particle (electron) is expelled from the nucleus with an energy up to one million electron volts or more. To derive power from the radio isotope it is only necessary to surround the Beta source with a Beta absorber at a separation sufficient to prevent arcing (in vacuo).



A compact battery would consist of alternate plates of Beta emitter and absorber. The rate of decay, and therefore the current capacity, is constant over a short interval, but decays to ½ its initial value after one half-life period. The voltage is dependent only upon the external circuit, since the emitted electrons are capable of crossing a barrier of up to one million volts.

In selecting the isotope to be used, consideration must be given to the application and to the possibility of radiation damage. For a short-lived missile, a fast decaying isotope will give the most power per pound. With too short a half-life, however, handling becomes a major problem. A permanent satellite might require a half-life of many years. By selecting isotopes that emit Beta rays alone without any gama radiation, by-product



ENGINEERS

Honeywell's "balanced" diversity brings you more opportunities

This Supervisory DataCenter, which enables one man in one location to control an entire air conditioning system for a large building, is just one of Honeywell's advanced automatic control products for civilian use. Honeywell also develops and produces advanced control devices and systems for the home, farm, industrial processing and factory automation.

Honeywell's Ordnance Division develops and produces such military products as: warheads; infrared systems and components; transistorized converters, inverters and rectifiers; test, checkout and training devices; thermal batteries; electronic fuzing; sonar systems; fire control systems and stabilized platforms.

HONEYWELL, world leader in automatic controls, is following a planned development program which is soundly balanced between civilian and government contracts. This program is giving Honeywell the fastest growth rate in its seventy year history. Earnings have more than doubled in the last five years. The engineering force has increased over 100%.

And Honeywell's exciting growth is continuing. To sustain it, we need skilled DEVELOPMENT, DESIGN, PRODUCTION AND ANALYSIS ENGINEERS to work on the types of products listed above.

You will receive the opportunity to grow with Honeywell, the fastest growing company in America's fastest growing major industry—the Electrical-Electronics industry. You'll work in a small group, your accomplishments will be quickly recognized, rapidly rewarded. You start with a first-rate salary, advance quickly from there. Start today.

radiation can be limited to soft X-rays due to Bremsstrahlung, or slowing down of the electrons in the absorber.

If radiation damage due to gamma rays can be neglected or shielded, a much larger selection of isotopes is available, many of which are fission products. In addition, the power per pound may be doubled by the use of an isotope whose daughter also is a Beta emitter.

Pr^{148} is a fission/product Beta emitter (without gammas) with a half-life of 13.8 days. A simple calculation shows that 0.176 amperes per pound of fuel can theoretically be obtained. Weight of the absorber, geometrical considerations, and reflection will probably reduce this figure and those below by a factor of ten or one hundred.

S^{35} with a ½ life of 87 days gives 0.116 amperes per pound.

T_m ^{171} with a ½ life of 1.9 years gives 0.003 amperes per pound . . .

Lyon McCandless, Jr.
4016—91st S. E.
Mercer Island, Wash.

To the editor:

In your February article "Russia's Guided Missile Program," noted photographs under heading of "Comparison of Some Typical USSR and USA Ballistic Missiles."

It has been my impression that the Honest John is definitely a rocket and not a "ballistic missile." Yet your heading does not mention rockets which to me is misleading especially at this stage of fog in the nuclear field.

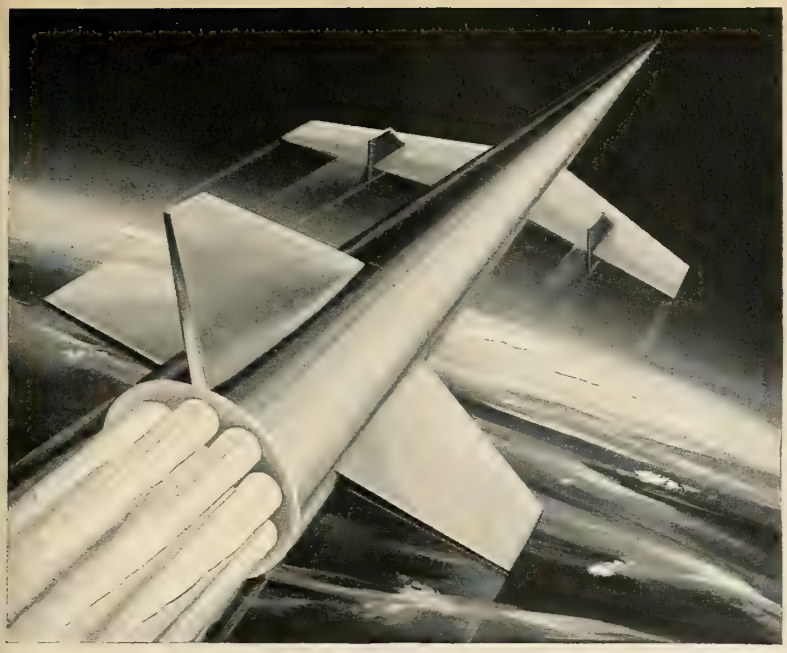
My interest is that I am presently doing periodical abstracting; that is writing abstracts of articles appearing in periodicals for use by Transportation School Library at Ft. Eustis, Va.

Lorraine Wingerter
700 Jamestown Road,
Williamsburg, Virginia.

A ballistic missile is one that, once it has received its initial launch boost to speed, proceeds in a trajectory governed solely by natural laws, such as gravity, wind resistance, etc. ICBM is not guided once the last stage burns out and falls off. Honest John is aimed and fired. Once launched, it becomes ballistic. Both ICBM and Honest John are, of course, rockets. —Ed.

Credit to Md. U. Students

To the Editor:



In the article on the Terrapin rocket . . . technical and the graduate assistants from the University of Maryland, unfortunately were not identified. Since they made a most important contribution to the program, I wonder if you could print their names: G. Bentley, R. Bettinger, R. Elton, C. Reber. . . .

S. F. Singer
University of Maryland
College Park, Md.

Oh! That Russian Spelling!

To the editor:

I am sad to find some rough errors in Russian names in your article "Russian Dogs Probe Upper Air" . . . In Column 1, Page 31, you cite Pomfomolfkaya

Which of these PROBLEMS fit your fields of interest in ROCKETS?

Bell Aircraft long a leader in liquid rocket development, produces aircraft and missile propulsion systems embodying the most advanced design concepts. Major efforts of the newly organized Rocket Division are directed toward the design and development of power plants, including turbine pumps, control valves, gas generators, pressurization systems and tanks.

Some of the problems which are under extensive investigation by the Rocket Division are:

1. Devise a method to study the formulation of propellant jets and droplets on injection and follow their behavior during the phases of mixing atomization, evaporation, and combustion.

2. Determine by means of specially designed apparatus, the coefficients of heat transfer to a liquid in the non-boiling, nucleate boiling, and film boiling regimes as functions of pressure, velocity, and bulk temperature.

3. Conduct an analysis of each component entailing fluid pressure losses, speed of operation, expected variations due to minute flow change and their effects on the component operation.

4. Plan testing and data analysis for liquid rocket engine design and development to overcome problems involving extreme temperature operation, turbine speed control, reliability, serviceability and maintenance.

If your qualifications place you in a position to help solve these challenging problems...or if you are now limited in the scope of your opportunity and would like to participate in any of Bell's widely diversified activities in other fields, write today: Manager, Technical Employment, Dept. U10, Weapon Systems Division.

Getting Talos Off to a Good Start

DESIGN
ENGINEERING
DEVELOPMENT
PRODUCTION

For its initial flight, the XX*-ton Talos ram-jet missile is pushed skyward by a powerful booster rocket. In a split second from launching, internal pressures are up to XXXX* psi . . . nozzle temperatures to XXXX* F. To design and produce a unit to endure such sudden torture called for an unusual combination of specialized engineering and fabricating skills. A major responsibility for the Talos rocket case was assigned to The M. W. Kellogg Company

Since 1951, M. W. Kellogg has been closely associated with the development and production of propulsion units for a wide range of missiles. Kellogg's most recent contribution is the development of reinforced plastic for rocket cases, using a unique filament winding method which produces structures of unparalleled accuracy and light weight.

To that rare breed of men who can

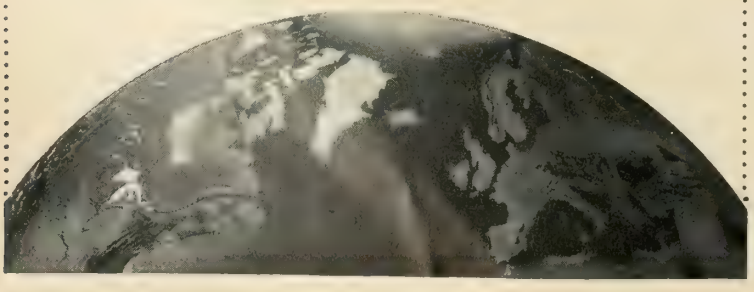
"see" the shape of things to come:

We can use your ideas in Large Rocket Engineering

We have a small but heavyweight group here at Rocketdyne known as the Preliminary Analysis & Design Section.

These are our idea men. It's their job to see the Big Picture... to approach outer-space projects without earthbound prejudice ...to anticipate problems and sense the likeliest ways to solve them. They are qualified experts in a broad range of fields. Some have extraordinary imaginations; others are brilliant analysts; but all share the ability to hit the highlights without becoming enmeshed in the details. In short, they are scientific skirmishers who scout each new challenge—then summon research and development specialists to meet it.

If this sounds like *your* kind of group, you may be the very man we're seeking for one of the several jobs now available. We can't describe them in detail here, but they include *Controls, New Concepts* (nuclear and ion applications), *Preliminary Design, Fluid Mechanics, Heat Transfer, Engine & Missile Systems,* and *Military Operations Analysis.*



We can use men with advanced degrees and solid experience in control systems and power-plant design. If you are a young engineer or physicist with an M.S. or Ph.D. and an analytical turn of mind, we can offer on-the-job training in many pioneering fields where experience is practically nonexistent.

Please tell us about yourself—what you've done...what you'd like to do. Write: A. W. Jamieson, Rocketdyne Engineering Personnel Dept. MAR-41, 6633 Canoga Ave., Canoga Park, California.

letters

Pravda whereas it should have been Komsomolskaya Pravda, and you write of Professor Bladolravo instead of Bladonravov. In Column 2 you speak of Pokrovsky without giving his first name or otherwise identifying him . . . clearly included Pokrovsky's first name Alexis, and indicated his authorship of that account.

Your magazine is widely respected as a truly reliable scientific publication. No doubt it is zealously and jealously watched by Soviet Russians. Why expose your data and your reputation to criticism by Soviet Russians and possibly also by some of your American readers who know the Russian language, and who may soon begin to make "cracks" about your "abuse" of Russian names and words?

Such errors are mostly the result of hurried typing and typesetting and not enough proof-reading.

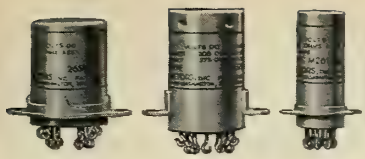
Definitions for Missileers

To the editor:

In our discussions of Rocketry, my associates and I have had some differences of opinion on the scope of some terms.

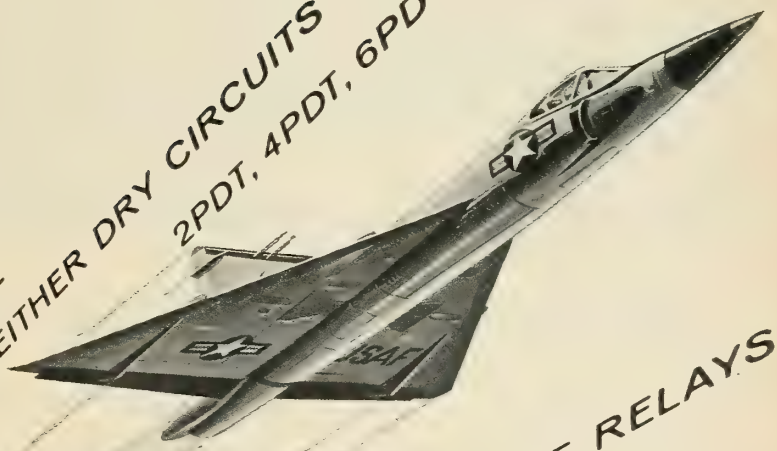
The terms in question are:



1. Rocket
2. Missile
3. Astronautics
4. Astrionics

We feel that you are the authority in this field, and have decided that we would all accept your definitions. Therefore, I am requesting that you send us your definitions of these terms.

Thank you for your assistance in this discussion.



John E. Heunessey
Glenn L. Martin Co.
Mail R536
Baltimore 3, Maryland

Traditionally a rocket is a vehicle propelled by a combustion motor which is entirely independent of external assistance, as from the atmosphere, for supporting combustion. It seems likely, however, that the term will develop to include any propulsive system which is independent of its immediate environment such as ion and photon systems and thermo nuclear propulsion. We but Webster's definition of the word missile: "Capable of being thrown, hurled or projected so as to strike a distant target. A missile weapon or object, as a spear, arrow or bullet; also, self-propelled pilotless weapon, as a rocket or a robot bomb." Astronautics is the science that treats with or pertains to the operation of space craft, in contrast to aeronautics which concerns itself with aircraft. Astrionics pertains to the science, engineering and use of electronics as related to extra-atmospheric or space flight. It is obvious from these definitions that the missile isn't new but dates back to when barely-developed man first threw a rock at a Mastodon. Modern man has merely managed to give the "rock" sophisticated propulsion and some semblance of guidance. The definition of "missile" remains the same.—Ed.

TORTURE TESTS like these for Syncroverter Switches are typical of Bristol's continuing drive for product quality.

100 billion operations and they're still going strong!

Syncroverter Choppers have run almost six years continuously at 400 and 600 cycles per second

That's the laboratory shelf-test record of a group of Bristol's® Syncroverter® Switches that are being run at no load as a test for actual mechanical wear out. They are still operating after almost six years.

These Syncroverter Switches are predecessors of those being used in aircraft fire control systems, guided missiles, electronic instruments, ground control equipment, and many other electronic systems.

Long life is a feature of the miniature Syncroverter Chopper and High-Speed Polar Relay. They are unaffected during severe shock and vibration and are available with the typical operating characteristics shown in the tables at right. They meet a wide variety of requirements. Write for further information on these precision components. Or we'll be glad to discuss specific application problems with you. The Bristol Company, 173 Bristol Road, Waterbury 20, Conn.

TYPICAL CHARACTERISTICS

Bristol's Syncroverter Switch (covered by patents)

Driving frequency range:	0-2000 cps (400 cps used for these characteristics)
Coil voltage:	6.3V sine, square, pulse wave
Coil current:	55 milliamperes
Coil resistance:	85 ohms
*Phase lag:	55° ± 10°
*Dissymmetry:	Less than 4%
Temperature:	—55°C to 100°C
*Switching time:	15° ± 5°
Operating position:	Any
Mounting:	Flange or plug-in—fits 7-pin miniature socket

These characteristics based on sine-wave excitation

Bristol's Syncroverter High-Speed Relay (covered by patents)

Temperature range:	—55°C to 100°C
Operating shock:	30G; 11 milliseconds duration
Vibration:	10-55 cps (see below, mounting): 10G
Contact ratings:	Up to 35V, 45 microamperes
Stray contact capacitance:	Less than 15 mmf.
Pull-in time (including bounce):	As low as 200 microseconds
Drop-out time:	300 microseconds
Life:	Over a billion operations under dry-circuit conditions
Mounting:	Octal tube socket; others available, including types for vibration to 2000 cps

Pratt & Whitney Aircraft measures jet fuel/air ratios ..in five seconds

How do you get rapid, accurate data on the fuel/air distribution within a jet engine? Pratt & Whitney Aircraft's new dynamic sampling system has solved this long-standing problem of the aircraft industry. In the first few minutes of operation, the Consolidated System proved capable of measuring fuel/air ratios continuously and automatically—providing plotted data never before obtainable so rapidly and so easily.

The complete system consists of a CEC 21-620 Mass Spectrometer and a constant-pressure, explosion proof manifold which does the sampling through a probe in the burner chamber. Gas samples reach the mass spectrometer 75 feet from the test burner in five seconds. The CEC System also makes it possible to follow thermal cracking and reforming of fuel components within an engine at extremely high temperatures.

THE CEC 21-620 MASS SPECTROMETER

is ideally suited for process-stream or atmosphere-monitoring applications, especially when higher molecular weight gas or liquid components are involved . . . provides accurate readings in the range of mass 2 to mass 150. For detailed information, please contact your nearby CEC field office, or write for Bulletin CEC 1824-X17.

At DOUGLAS

...your missiles assignment can be as big as your talents

Now in its 16th year, the Douglas missiles program is projected far into the future by such exciting new projects as THOR

Out of such veteran projects as Nike and Honest John are coming fantastic new missile systems to challenge the finest engineering talents in the land.

Since early in World War II, Douglas has been engaged in missile projects of prime importance. New engineering teams are constantly being formed for research, design, development and production. Engineers advance rapidly as Douglas expands its leadership in this challenging field.

You are stimulated to accelerate your career by the importance of each assignment ... by the help of your associates who are recognized experts in missile work ... by the vastness of opportunity for engineers in this company that is run by engineers.

There is no more promising future than that which awaits you in the Douglas Missiles Divisions.

THOR—*an intermediate range ballistics missile now under development—has top priority in our country's program for national defense.*

ABMA Obeys Wilson; Tailors *Jupiter* to AF Needs

Denies Lack of Cooperation With AF Missile Evaluators

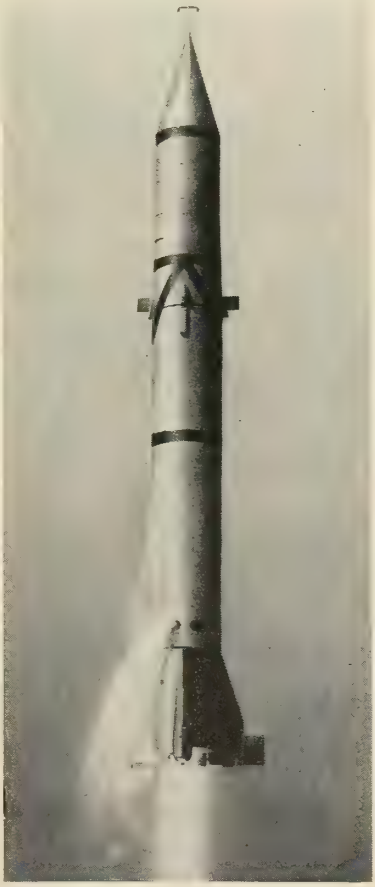
In an exclusive report m/r learns that:

Gen. Medaris never denied any Air Force JUPITER evaluation team entrance to Redstone Arsenal.

ABMA chief expects need for manned tactical air support may disappear by 1967.

Development of successful inertial guidance for long range ballistic missiles is an accomplished fact.

JUPITER development is going ahead full tilt with special emphasis on AF requirements.



In its March 18 issue, *Aviation Week,* ran a story announcing that Maj. Gen. John B. Medaris, Commanding, Army Ballistic Missile Agency, had refused a U.S. Air Force evaluation team admission to Redstone Arsenal which had been sent, the magazine claimed, "on direct orders from Defense Secretary Charles E. Wilson."

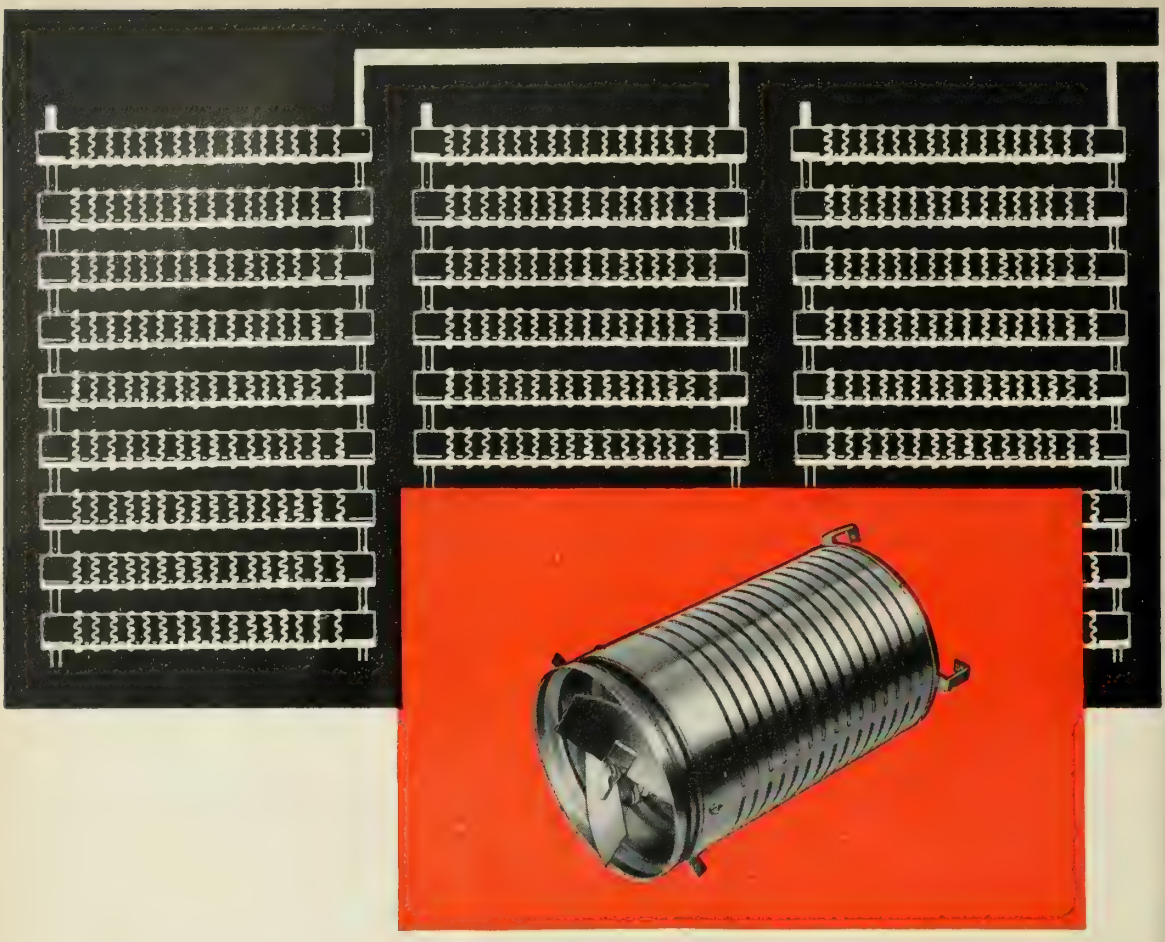
On March 18, Brig. Gen. J. A. Barclay, deputy commander, ABMA, issued the following statement in answer to press inquiries:

"On Nov. 28, 1956, the Army through a personal visit of Maj. Gen. J. B. Medaris, Commanding General, ABMA, to the office of Lt. Gen. T. S. Power, Commanding General, Air Research and Development Command, Baltimore, Md., extended an invitation to the Air Force to visit the Missile Agency to be oriented on the Jupiter IRBM program. While the Air Force has not availed itself of the invitation, it still stands.

"The Agency has never denied entrance, or access to information, to the Air Force.

"There has been complete liaison between the Air Force and the Agency since its establishment Feb. 1, 1956. An Air Force officer is a member of the Commanding General's staff. In turn, the agency has its own liaison officers at the Western Development Division of the Air Force in Inglewood, Calif., and at Patrick AFB, Fla., where work in support of ballistic missile development is carried on. As a result, there has been a free flow of information between the Army and the AF.

"Weaponization" of Army's REDSTONE means missile may soon be delivered to the field for operational use by combat troops.



"In December, 1956, representatives of a civilian contracting firm engaged in development activity associated with guided missiles sought permission to enter the Agency for the purpose of evaluating our work. Since the firm was a direct competitor, it was considered inappropriate for them to evaluate the *Jupiter* missile.

"On March 19, 1957, representatives of WDD will attend a critique at ABMA on recent missile firings. Gen. Medaris will be visiting Maj. Gen. Schriever . . . during the current week on a West Coast tour of contractor facilities which had been planned for some time."

In an effort to clarify once and for all the Army's official position in the *Jupiter-Thor* dispute, m/r requested and was granted an exclusive interview with Gen. Medaris. m/r asked him first about the incident noted above.

Confirming the content of the press release quoted above, he went on to say that "any situation that did not allow the free flow of information between the armed services would be intolerable. All technical reports on our missiles are available to all government agencies involved in ballistic missile programs or having any interest in them. We answer their inquiries promptly on any details. WDD has an officer in my Agency who gets any information he wants, and who obtains for me any information I need about AF developments. It is perfectly ridiculous to imply that there has been any holding back of information between Government agencies in this business."

Next, m/r asked Gen. Medaris if Wilson's roles and missions memorandum had harmed ABMA. He replied that it was Wilson's right to establish roles and missions among the services; that "this is not my field. My concern is building successful missiles. I can't

One Electric Power Absorber Now Replaces 27 (500 W) Stick Resistors

Saves 2500% on space. Saves 666% on weight.

The SUN ELECTRIC Power Absorber is designed for continuous duty up to 15 KW. The single unit, which replaces a whole bank of old-fashioned stick resistors, is light in weight and small in size.

Why the SUN ELECTRIC Power Absorber can save you money in your generator test operations:

- Weight—only 1 lb. per KW
- Rugged and shock-resistant
- Nichrome V-ribbon resistor offers maximum cooling surface
- Occupies only ½ cu. ft. space
- Fully protected against overload
- Motor self-cooled, can be made part of load or operated by an external source of power
- Cadmium-plated dichromate finish meets military specifications

see any real connection between the color of uniform worn by the user and the agency that develops his weapon. Obviously it should be the agency which has the best facilities and the most capable people. We in the Army have made weapons for many years for the Air Force, the Navy and the Marine Corps. The Navy has made weapons for the Army. Whoever has the knowledge and the capability to complete the job in the shortest time should be selected. We cannot tie our developmental programs solely to the user."

Commenting on the advisability of continuing competing IRBM projects such as the *Jupiter* and the *Thor*, the ABMA Chief noted:

" I suppose the element of competition appears stronger in this case because two different services are involved. Actually there is competition in the ICBM field as well—but because it is between industries and under the aegis of one service, there is less press interest. There has to be selection in the field of new and vital weapons and the greatest intelligence must be exercised in determining where you can place your effort with maximum assurance of success. The broader approach with competition may be the only guarantee of producing one successful weapons system in the shortest time span. We cannot afford to back up and start over if we find the initial approach was wrong. The dual approach is justified if you have any doubt as to the positive success of a single effort on the required time scale.

"We are definitely going ahead with the *Jupiter*. We believe we will provide the country with a successful intermediate range ballistic missile. The time will come when a decision can be made as to selecting one of the IRBM systems for continuance. We are bending every effort to be at the forefront when that time comes. Somebody has to come up with the right answer. The country needs it."

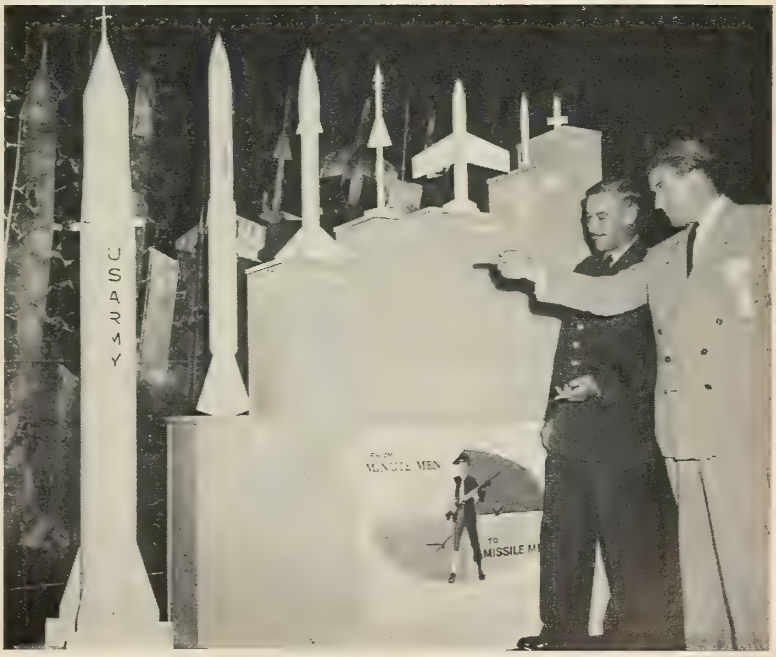
He noted that since the agency was set up in February, 1956, ABMA had had practically no loss or turnover in scientific and professional personnel, but that, rather, many additional graduate and post-graduate scientists had been and were continuing to be employed. "I believe," he said, "our success can be explained by the fact that these people like the continuity of effort and the team spirit of a closely knit organization working on a complete missile project under one roof."

Asked how he felt about the fact that the AF had been designated the user service for IRBM's, Gen. Medaris replied that "we are working with an eye to the customer's needs. The project is going forward in the interest of the Air Force."

We then asked him when he thought the guided missile would replace the airplane. Stating that this would happen as aircraft became more vulnerable and as missiles took on added capabilities, he pointed out that increased missile use had already resulted in a cutback of tactical airpower.

"Our concern," he said, "must be to avoid exposure of personnel, particularly highly trained men, where the chance of survival has been lessened. If we confine the estimate to tactical air support, I would say it may be possible to relieve the air arm of this task in 10 years.

"However, there is no such thing as the ultimate weapon. In its time and place, that could have been said about gunpowder. There is always a contest between offense and defense; right now, offensive weapons are outrunning the defense in development. But inevitably the scales will tip back . . ."



Asked what is behind the Army and Navy philosophy of relying chiefly on their own ordnance installations for missile development, whereas the AF relies on private industry, Gen. Medaris noted that the AF is used to dealing with the aircraft industry, but from the Army's point of view "when you talk missile development, you are dealing with a relatively new and highly complex art. Missiles require the application of all the physical sciences and the exploration of unknowns. There was no reason why industry should have built up a full-scale, balanced team capable of dealing with long range guided missile projects.

"These enterprises require the capabilities and experience of a completely integrated group, working in one place, so that you get the benefit of daily interaction between people whose abilities and problems are well known to each other. Then you have maximum efficiency. That is what we require. It's not a question of industry vs. government.

"At present it's possible to achieve this kind of integration only in government installations. If the missile field continues to broaden, however, some major industries will, over a period of time, develop fully integrated and capable missile teams of their own. Then the situation in those industries would be comparable to that we enjoy in my agency today."

Gen. Medaris refused to give any details when questioned as to ABMA's current missile development activities beyond saying that "weaponization" of *Redstone* was under way and that work on *Jupiter* was going ahead. He stated his view that "there has been too much publicity about missile projects and progress. If the other fellow knows what's coming, it makes it much easier for him to decide where to put his effort. It's not my job to help him."

Next, m/r asked him what he thought was the major factor in further missile development. He said that he

Maj. Gen. J. B. Medaris and top Army missile maker Wernher von Braun view their work.

believed the guidance factor has been licked and that from here on, "it is largely a matter of more efficient and more powerful propulsion systems." He stated that though today's systems were pretty good, they were, relatively speaking, at about the same stage of development automobiles were in 1940. He added that the preference for liquid or solid propellant systems depends on the job to be done; that sometimes the optimum solution to a missile problem requires both.

When asked if he thought the U.S. was ahead of Russia in the missile race, he said:

"I believe that in any area where it has been decided that it is essential to national security that we have operational missiles, or missiles in development, we are ahead and we can stay ahead. I have to qualify that by saying that the element of judgment is always there. It is impossible, with available resources, to develop everything we know to be feasible. So a high degree of selectivity is necessary. Each nation must make its choice of weapons based on the conditions which confront that nation. The circumstances confronting the Soviet Union and its Satellites, for example, are quite different from those which we must consider. The matter of selection in weapons must reflect the whole atmosphere of our defense against any threat of war."

Navy Converts *Loki* To Sounding Rocket

U.S. Naval Ordnance Laboratory has converted the Army antiaircraft missile, *Loki*, into a 100,000-foot altitude weather sounding rocket.

Called the *Hasp*, the missile is a single-stage, solid-propellant rocket that can be fired from conventional 5-inch Naval guns. Rocket motor and the dart, the smaller forward part, ascend as one unit to 2600 feet where burnout and separation occurs. The dart coasts upwards to 100,000 feet, at which point a timing device splits open the nose and ejects instruments to detect temperature and humidity in the ionosphere. Instruments return safely to earth by means of a balloon, meanwhile telemetering data from the various atmospheric layers through which it passes.

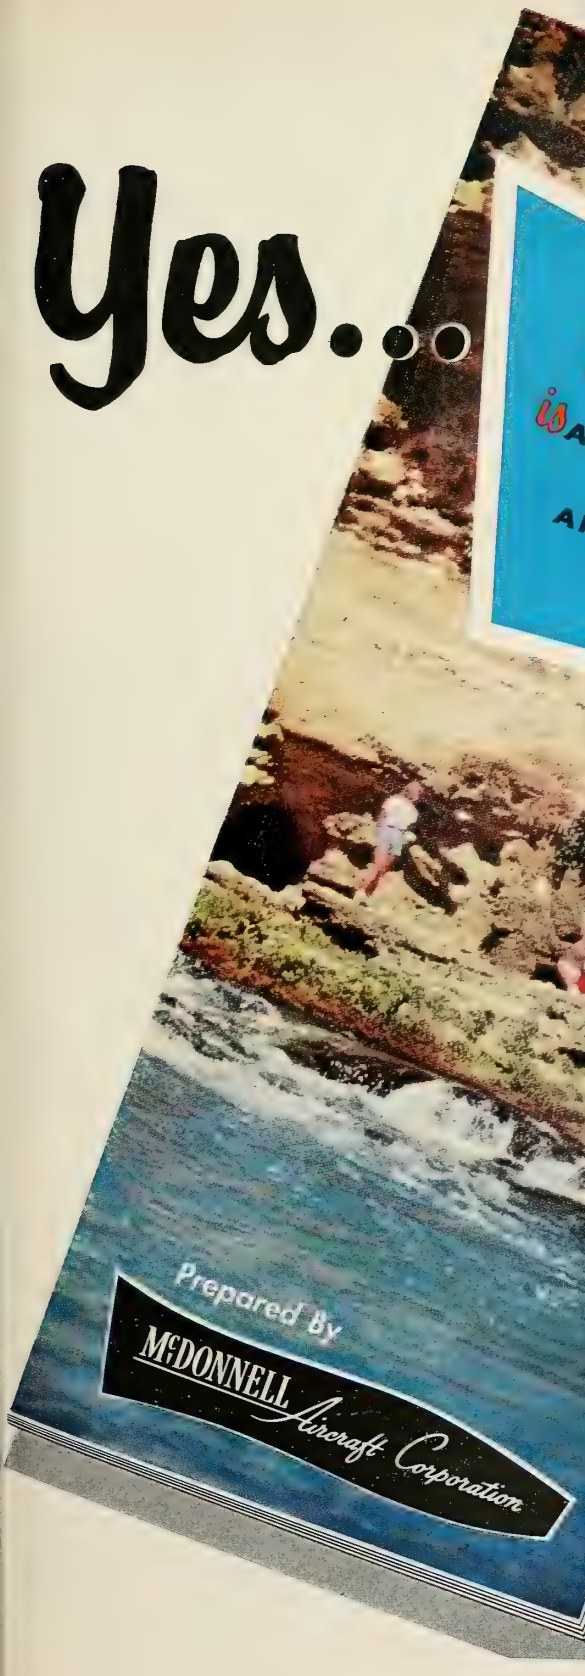
The *Hasp* dart was designed by J. L. Walthall, Jr., NOL project engineer. Project manager D. R. Williams expects to make the system good to 300,00 feet after modifications. First *Hasps* were fired last January, marking the first time weather rockets have been fired from a Naval rifled gun.

Launching Platform Ready for *Vanguard*

The firing and launching platform for *Vanguard* has been designed, built and installed in position at Patrick Air Force Base, Fla.

The platform will be used for testing and firing the huge, three-stage rocket which will attempt to place an artificial satellite in orbit around the earth. This is in support of U.S. participation in the International Geophysical Year, 1957-1958.

In the past, a single, large missile firing structure was limited in function to launching purposes and was not capable of static-testing and performance evaluation. This structure designed and built by the Loewy-Hydropress Division of the Baldwin-Lima-Hamilton Corp., not only launches the rocket but statically tests and evaluates performance as well.



Under its sub-contract with Glenn L. Martin Co., the Loewy-Hydropress Division will also be in charge of complete stand instrumentation, support stand mechanisms, as well as utilities and preliminary research—such as heat stress analysis.

This division of Baldwin-Lima-Hamilton Corp. previously made international news with the completion of the world's largest press—the 50,000-ton forging press for the Air Force Heavy Press Program.

The public record shows that construction of the *Vanguard* static test and launching platform is only one of a number of important missile contracts held by Loewy. The stability, strength and close tolerances required for large missile launching equipment is a natural for companies used the design and manufacture of heavy precision production equipment.

This exclusive shot of the VANGUARD launching platform shows Navy VIKING ready to go. Loewy-Hydropress Div. of Baldwin-Lima-Hamilton Corp. designed and built the structure.

ENGINEERS . . .

Would you like to learn how the "MAC Engineer" lives and plays? This pamphlet contains color pictures of typical middle-income homes in suburban St. Louis, and actual figures of cost, taxes, and utilities. With each home are pictures of nearby public schools. Also, cost comparisons are made with other areas concerning general cost of living, state gasoline tax, and state income tax. A two-year weather picture is included.

We have not attempted to describe the "hospitable nature" of our neighbors. We hope you and your family will discover this for yourselves.

THE MIDWESTERN 561 RECORDING OSCILLOGRAPH

561 SPECIFICATIONS

Weight	15½ lbs.
Dimensions	6-11/32" x 5-3/16" x 9-3/16"
No. of Channels	14
Magazine Capacity	95' DuPont Lino Writ #4
Recording Speed Range	0.5" to 80" per sec.
Trace Identification	Beam Interrupter Type
Constant Acceleration	Above 25 Gravities
Shock Accelerations	Above 1500 Gravities for 20 Milliseconds
Temperature	—65°F to +165°F
Altitude	Up to 100,000' above sea level
Power Requirements	28 volts DC, 12 Amperes Maximum
Connectors:	
Power	WK 5 32S
Galvanometer	FK-C32-32S

This new recording oscillograph now makes it possible to eliminate costly telemetering equipment in missile, torpedo or similar testing. Its miniature size, extreme ruggedness and high recording speeds allow it to be installed directly in the test vehicle, where it will record all data and will withstand the high shocks and accelerations associated with the test.

New Telemetry Era for ICBM'S and Space Flight

by Henry P. Steier

NEW YORK—Recognition was given at the 1957 National Convention of the Institute of Radio Engineers to the advent of a new era in telemetry, as man extends his need for radio information and remote control into outer space. A symposium on long range telemetry and remote control was featured at the convention.

M. V. Kiebert, Jr. who chaired the symposium described telemetry as a most important link in man's new search for space-knowledge.

Some years ago, Kiebert noted, he gave a paper in London, England at a joint Royal Aeronautical Society and Institute of the Aeronautical Sciences meeting, pointing out the impending obsolescence of pilots as a means of obtaining information.

As a pilot talking to pilots, he said, the statement was met with raised eyebrows and embarrassment from the audience. But now ten years later that day is here.

Some of the forerunners of pilot substitutes are already seen, Kiebert maintains, in automatic equipment on board the Boeing 707 jet transport, and when the rocket-powered aircraft arrives the pilot will be little more than the executive in charge of the flight.

Compared to future equipment and precisions, present day know-how is quite primitive. However, the first really head-on encounters with telemetry and remote control over long ranges and with high velocity vehicles are being experienced.

At this time engineers are wrestling with these experiences in military work on IRBM and ICBM test vehicles that are part of the vast R&D effort underway on these weapons systems.

A review of progress in telemetering of data from the Lockheed Missile Systems Division X-17 re-entry test vehicle was given in a paper prepared by Dr. R. J. Burke of the division, and delivered by N. Terveen, also with the missile division.

Terveen noted the relatively low cost of Lockheed's vehicle compared to an imaginary 4-passenger space ship. An airframe executive, Traveen said, has estimated the space ship would cost "$.3 x 10^9" whereas the X-17 without equipment on board costs "$.35 x 10^8," or 1000 times less.

The X-17 weighs about 6-tons. It is about the height of a four-story building and has three stages.

Before beginning with the basic tests for which the X-17 was conceived, Terveen said many flight tests had to be made to develop telemetry instrumentation and telemetry systems which would give assurance of getting back accurate data.

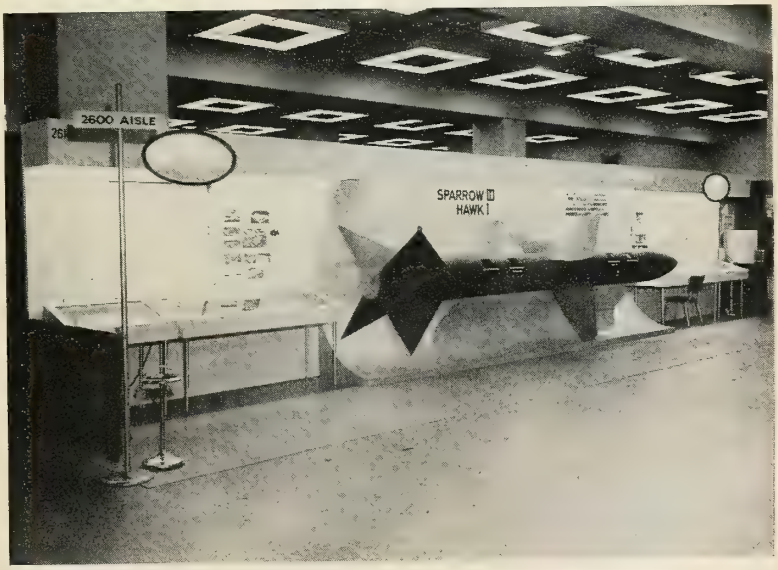
One difficult design area was joining the stages. The joints must be near perfect. They must take the structural loads and maintain rigidity and yet be able to separate easily.

If separation does not take place properly, the flight path or trajectory does not go as planned. Deciding whether a flight malfunction was due to poor separation or poor aerodynamic design was a problem for telemetry.

Another was determination of timing for first stage separation versus firing of the second stage. Second stage rocket nozzles when fired cause turbulence that can destroy everything in their vicinity. Instrumentation can be wiped out in a fraction of a second, and also the nozzles can be destroyed.

Instead of the usual break-wire strain gauges often employed, Lockheed used variable reluctance gauges applied to the principle tie bolts in the structure. Other gauges were used to indicate if the first stage did not return to earth after separation. What they got on the ground from this telemetry was pressure-time curves.

Each pound of instrumentation used in the third stage accounts for 140 pounds of gross take-off weight. A little over 14 pounds of such gear would mean an added ton of weight.



For its X-17 work, Lockheed engineers have developed a modified RDB standard commutation system that permits much better use of the inherent channel capacity by eliminating need to devote one-half the channel to signal synchronizing.

Fighting the weight-volume problem, Lockheed originally used an 11 ounce vacuum tube operated sub-carrier oscillator occupying 14 cubic inches. Now a 1¼ ounce system weighing 2/3 ounce and operating with transistors has been developed. The problem of temperature compensation was met making transistorization feasible.

Several of these have been flight tested and maintain temperature stability of less than 1 percent over the entire temperature range encountered in the tests.

The system carried aboard the X-17 is FM/FM operating in the 215-235 telemetry band. Control is by crystal and output is 2 watts.

A big part of the job of this system is concerned with temperature information from thermocouples mounted in the vehicle's nose cone.

Quiet moment near Raytheon Mfg. Co's 1½-times actual size HAWK model. Rubber tail-fin ball saved many an eager eye: Slides were shown through missile's windows.

This New 400 Cycle AC Rotary Actuator by

EEMCO

Has an Operating Range of 320 to 480 Cycles ★

EEMCO Type D-822 400 cycle rotary actuator controls the trailing edge flap on the latest and fastest supersonic fighter aircraft now in quantity production for the United States Air Force.

★ One of the unusual features of **Type D-822** is that it operates on a frequency range of 320 to 480 cycles whereas Military Specification requirements call for a range of but 380 to 420 cycles for AC actuators and motors. The greater range eliminates need for a constant speed drive for the generator system in the aircraft which cuts down possible maintenance and at the same time reduces overall cost and weight considerably.

A torque-limiting AC clutch is incorporated in the motor in **Type D-822** which disconnects the high inertial load imposed by the motor's armature. A brake can be built into this mechanism if **Type D-822** is altered for use in some other capacity. Another feature is the adjustable non-jamming stops that are built into **Type D-822** which are especially vital on an actuator with this load magnitude.

For the past 15 years EEMCO has made a specialty of designing and producing special AC and DC motors and linear and rotary actuators for the aircraft industry. Its entire effort has been in this field. Reflecting the high standards of precision gained from this experience is the fact that EEMCO motors and actuators are included in the majority of the latest jet aircraft and missiles now being produced for our national defense.

SPECIFICATIONS FOR TYPE D-822

Normal operating load: 26,000 inch-pounds
Maximum operating load: 52,000 inch-pounds
Ultimate static load: 75,000 inch-pounds
Travel: 45 degrees at .625 RPM
Amperes: 4 amps. at 26,000 inch-pounds at 480 cycles on 200 volts
Weight: 35 pounds
Qualification: Type D-822 has been designed and qualified to meet applicable military and aircraft manufacturers' specifications.

EEMCO **ELECTRICAL ENGINEERING & MANUFACTURING CORP.**

4612 West Jefferson Boulevard, Los Angeles 16, California—Telephone REpublic 3-0151

DESIGNERS AND PRODUCERS OF MOTORS, LINEAR AND ROTARY ACTUATORS . . . EXCLUSIVELY!

Terveen said instrumentation of the nose cone was a formidable task. The cone must be micro-smooth. The smoother the cone the more easily is heat transferred to the atmosphere during the re-entry flight.

If slight irregularities exist on the cone a "turbulent boundry layer" occurs which transfers heat to the cone at a high rate. Placing thermocouples must be done without disturbing either the smoothness or the homogeniety of the metal used.

A complex fabrication technique to do this has been worked out. Two problems remain. These are how to measure pressure at the nose cone, and what amount of metal has melted and blown away. One way to aid reduction of nose cone heating might be to remove large amounts of heat by designing for dispersal of molten metal.

An intriguing problem is what happens to radio signals that try to get through the highly ionized atmosphere around such a vehicle as the X-17.

Although Lockheed admits it has experienced a "peculiar phenomenon observed in the variation of radio frequency field strength under X-17 flight conditions" military security is close-lipped on just what has happened.

Long Range Telemetry

According to J. B. Wynn, formerly with the RCA missile test center, Melbourne, Fla. and now vice president Century Electronics Corp., significant changes in test range instrumentation have taken place in the last year.

The most noticeable changes have taken place in the case of radio telemetry equipment being installed by the Air Force at its Missile Test Center.

Whereas flight to an apogee of 100,000 feet, or about 20 miles was the maximum a few years ago, today it is realistic to talk of apogees of 300-600 miles, Wynn noted in a talk on long range telemetering reception.

At apogees near 500 miles the slant range to vehicles is around 2200 miles, and for tests on ballistic missiles achieving these ranges the Air Force has developed new high gain telemetry antennas for ground acquisition of data.

The old 2½ turn helical antenna served for five years, and in 1952 its gain was boosted to give 10-12 db by using a 7½ turn system. These gave reliable 200-mile range coverage for each site on the AFMTC range.

With the advent of ICBM tests, the Air Force now needs antennas with a 30 db gain to provide real-time data from these new, long range vehicles.

The first of these is about to begin operation. Even the longest range radars with their megawatts of power and using a beacon transponder technique for data acquisition can no longer do the job.

Their usefulness becomes even more apparent when the re-entry aspects of data acquisition are considered. In event it is impossible to pick-up data during part of the trajectory because of ionization or other interference, the telemetry system using the new automatic tracking antennas would be able to acquire data long before any other system in use today, Wynn said.

Tracking accuracies of ± ½ degree have been achieved. The lower elevation limit has been set at 2 degrees and maximum at 86 degrees.

The new antennas are big. Comparing old and new, the 2½ turn helical antennas weighed 50 pounds with a 30 inch diameter reflector dish. The new ones weigh 72,000 pounds exclusive of electronics gear, and have a 60 foot diameter parabolic dish with a possibility they may go to 85 feet.

It is certain large numbers of them will not be needed. Wynn said one at AFMTC and one in the Northern part of the East coast could cover the whole coast.

Four of the antennas will be installed by the Air Force, and this gives some idea of the vast coverage planned.

The ultimate range of the new antenna systems is believed to be far in excess of the 2200 mile figure discussed by Wynn, who was restricted by security from revealing exact range.

Electronics Designs Studied for Bombers

General Electric Co.'s Advanced Electronics Center, Ithaca, N. Y. has revealed that the company has a long range program leading to development of defensive electronic sub-systems for nuclear or chemically powered bomber vehicles expected to be operational in 1970-75.

I. Katz, consulting engineer with the Center, revealed the program at a meeting during the IRE National Convention. He said the nature of the environment surrounding such vehicles traveling at more than 2000 miles an hour will be such that wholly new electronic equipment will be needed to "see" through the interfering acoustical, chemical or nuclear radiation envelope in the wake of such vehicles.

Propulsion systems which are an-

Honeywell's Variable Inlet Diffuser
Controls Keep the "Hustler" Hustling

ENGINEERS
SCIENTISTS

WORK ON ADVANCED PROJECTS LIKE THIS

As mach numbers advance, even fractional errors in inlet-air diffuser positioning reduce thrust tremendously.

Yet a fixed diffuser designed for optimum pressure at a given high mach number may be so inefficient at a lower mach number as to render it impossible for aircraft to reach design speed.

In the U.S.A.F.'s first supersonic bomber, Convair's B-58 Hustler, this problem was solved by Honeywell's variable inlet-air diffuser systems—the most accurate known. They are automatically controlled to the proper parameters to achieve maximum pressure recovery and mass air flow matched to engine requirements.

The Challenges to Come!

Variable inlet diffuser systems are just one of 114 research and development projects in which Honeywell Aero is engaged. These projects are in the basic areas of:

INERTIAL GUIDANCE • FLIGHT CONTROL SYSTEMS • LIQUID MEASUREMENT SYSTEMS • VERTICAL, RATE AND INTEGRATING GYROS • DIGITAL AND ANALOG COMPUTERS • JET ENGINE CONTROLS • AIR DATA COMPUTERS • BOMBING COMPUTERS TRANSISTOR AMPLIFIERS • INSTRUMENTATION

Each of these projects offers exceptional career opportunities for capable engineers and scientists.

And Honeywell's rapid growth assures you of early advancement. Engineering personnel at Honeywell Aero has tripled in the last 5 years, is still growing faster than the avionics industry average. Supervisory positions open quickly, are filled from within. The first-rate salary you start with at Honeywell is *just the start.*

Write today!

For more information concerning these opportunities, send your inquiry or résumé to: Bruce D. Wood, Technical Director, Dept. TA19B, Honeywell Aero, 1433 Stinson Boulevard, Minneapolis 13, Minn.

Honeywell
Aeronautical Division

ticipated would develop more power than the largest central power generating station anywhere in the world today, Katz said. Following the four engined vehicles will be a layer of gases at 4000 degrees R.

He predicted the noise level around the vehicle would be 190 db and inside would be 160 db. And, that an important new approach to electronic design would be required by the necessity to balance off equipment reliability against savings in weight through use of anticipated mission schedule as an index of how long the equipment should work properly.

NAA Ion Rocket Study Contract Let

The Rocketdyne division of North American Aviation, Inc., has been awarded a research contract by the Air Force to study the feasibility of ion propulsion.

Under the contract let by the Directorate of Advanced Studies, Air Research and Development Command, the division will explore ion propulsion as a possible source of economical power for missiles.

An ion propulsion system theoretically would obtain thrust by using high velocity charged particles, while conventional chemical rockets, ram jets, and turbo jets use high velocity hot gasses. Ions are atoms or molecules stripped of one or more electrons. In this form they are energized by electricity to create thrust.

Such a system would not produce anywhere near the amount of thrust developed by a chemical rocket propulsion system. At very high altitudes, an ion engine developing a few ounces or pounds of thrust might accelerate a vehicle weighing several thousand pounds to great speeds. To move the same vehicle at lower altitudes would require an engine developing thousands of pounds of thrust.

Because of its low consumption of fuel, an ion engine in theory would operate for several days or weeks. Conventional rocket engines consume fuel in a matter of minutes.

Ion propulsion is valuable only in the case of vehicles released well beyond the pull of the earth's gravity, say for example, about 24,000 miles out.

In this respect, the ion rocket would be a good second or third stage for a moon or interplanetary vehicle. Chemical rockets would provide the massive thrust needed to get beyond the immediate heavy pull of the earth's gravity.

LAMINATED SHIM COMPANY, INC.

SHIMS • STAMPINGS

Glenbrook, Connecticut • Stamford DAvis 4-5721

To Design Engineers and Production Engineers
Interested in Rockets and/or Missiles

Gentlemen:

When we read of avionics, of astronautics and of such miracles as photon propulsion, we're overwhelmed. We even wonder if it isn't merely the absence of the human pilot that makes an aircraft a missile. Or a rocket.

Frankly, we don't know about such things, and you do. That's why we come to you with a question.

What we do know is that it takes a lot of shims, laminated shims of Laminum, to build modern aircraft--because we supply the industry with custom-made Laminum shims in all shapes and sizes...in aluminum, stainless steel and in brass...so that components and structures may be accurately assembled... within limits of a thousandth, if necessary...with time-saving, cost-saving ease and efficiency.

Now, here's our question: what about rockets and missiles? Don't you consider their design in the light of precision assembly? Of ease in assembly? Of economy in assembly? If your answer is "yes", you will need all the detailed engineering facts you can get on the subject of laminated shims of Laminum.

So...here is your invitation to get these facts--straight from "Shim Headquarters". The coupon below is for your convenience; just fill it out and mail it now.

Sincerely yours,

M. L. Lockwood
Vice President
in charge of Sales

Laminated Shim Company, Inc.

NEW SWITCH NEWS

FOR CIRCUIT DESIGNERS

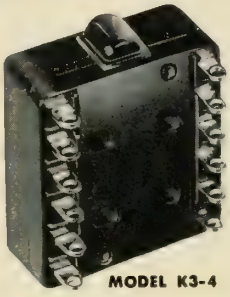
New subminiature sealed switch is environment-free; mounts interchangeably with MS25085

MODEL EF-3

Single Pole, Double Throw
Move. Differential, .004 Max.
Overtravel, .003 Min.
Oper. Force, 5 to 17 oz.
Release Force, 60 gram
Elec. Life Ratings:
150,000 ops. @ 125/250 V. A.C., 2.5 AMP.
100,000 ops. @ 125/250 V. A.C., 5.0 AMP.
50,000 ops. @ 30 V. D.C., (2.5 AMP., IND.; 4.0 AMP., RES.)
Amb. Temp., −65° to +180° F.

Sealed in a corrosion-resistant, treated aluminum enclosure, this tiny switch is environment-free; highly vibration and shock resistant. It carries 5 amps. at 125/250 V.A.C. with an electrical life rating of 100,000 operations. Low operating force and small movement differential make it ideal for bi-metal temperature, diaphragm operated and other "feather-touch" devices, while small size permits mounting singly or ganged in restricted space. Rugged and dependable, it has positive snap action.

Tiny, new 40 amp. basic switch has high capacity, longer life and constant stability of tolerances



MODEL G3-8

Measuring only 1¾" x 43/64" x 43/64", the new Electro-Snap G3-8 Basic Switch handles current ratings up to 40 amps. A new method of combining Electro-Snap's double-break action with a heavy-duty switching element assures electrical and mechanical life of 100,000 cycles at large capacities; also provides constant stability of tolerances and accurate repeatability. New plastic compound case gives the switch an ambient temperature rating of −65° to +300° F. with extreme shock resistance. Small size makes it ideal for motor controls and compact automation set-ups. A wide range of actuators is available.

OPERATING CHARACTERISTICS

Single Pole, Double Throw
40 AMPS @ 125/250 V. A.C.
@ 30 V. D.C. Res.
Oper. Force, 30 ozs.
Overtravel, .025" Min.
Move. Differ., .055 ± .010

New simultaneous triple-pole switch interrupts 3-phase ac. circuits; 6-circuit control in a small package

MODEL K3-4

Triple-Pole, Double Throw
15 AMP., 125/250 V. A.C.
30 V., D.C. Res.
10 AMP., 30 V., D.C., Ind.
Overtravel, .015 Min.
Move. Diff., .028 ± .007
Mech. Life, 1,000,000 ops.
Elec. Life, 500,000 ops.

This completely new Electro-Sna triple-pole switch simultaneous reverses current flow throug three windings of a 3-phase mot up to 1 H.P. and interrupts oth types of multi-switching install tions. Instantaneous "make" ar "break" snap-action of the thr poles is independent of the spe of actuation—even extreme slow moving cams can be used.

The K3-4 Series offers designe a wide variety of 3-phase circu hookups for servo-controls, limit movement of machine mer bers and as a start-and-stop swit which formerly were possible on with complicated relays or a nur ber of separate switches. A lar selection of standard actuato is available.

New small basic switch is low cost; directly interchangeable with AN3234 Specs

F2 SERIES

The new Electro-Snap F2 Series snap action switches are extra-compact with extremely high electrical capacity for their size. Mechanical and electrical life at 1/32" overtravel is 150,000 operations, minimum, with accurate repeatability and constant stability of tolerances. Self-aligning springs provide contact wipi action rare in a switch of this size.

Durable case of special plastic gives the switch an ambie temperature rating of −100° to +275° F. or +375° F. Ava able, *at low cost*, in three basic models with a wide selecti of actuators.

SERIES F2 BASIC SWITCH: F2-3: Single Pole, Double Throw
F2-2: Single Pole, Normally Open; F2-1: Single Pole, Normally Closed

OPERATING CHARACTERISTICS

Electrical Rating: 10 AMP. 125/250 V. A.C. 60 cycles
30 V. D.C. inductive and resistive (6 AMP, 30 V. D.C. for Airborne Applicatic
Operating Force, 7 to 12 oz.
Reset Force, 4 oz. Min.
Pretravel, 3/64 Max.
Movement Differential, .011 ± .0
Overtravel, 1/32 Min.

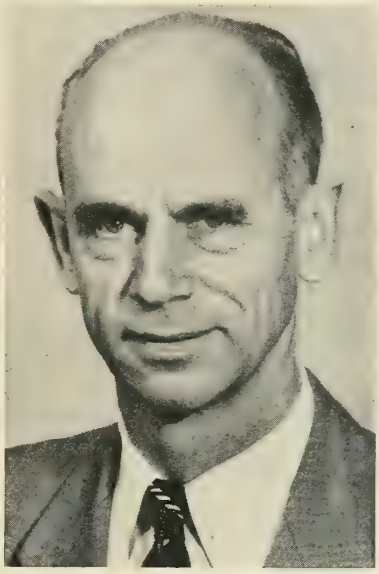
In addition, an ion propulsion system would be extremely useful in providing adjustment thrusts for keeping a 2000-mile high manned or unmanned permanent satellite in its orbit. At such an altitude there apparently are still "earth influences" as from traces of the atmosphere and some of the micrometeoritic dust and other particles that accompany this planet through its orbit. These will be bound to slow down any artificial satellite. Ion propulsion would certainly provide sufficient thrust to prevent such a vehicle from falling in out of its orbit.



There is also the very good possibility that studies of ion propulsion will provide new knowhow that will ultimately lead to much more ambitious projects, perhaps even bearing on the basic nature or gravity.

Space Flight Confab For Businessmen

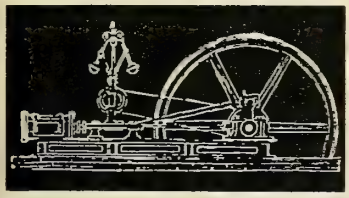
Advance reports on the "Age of Space" conference May 16th and 17th promise businessmen a practical short course in missiles and space travel.

Sponsored by the Southern Research Institute, the two-day meeting includes a *Redstone* test-firing demonstration at Redstone Arsenal.

Speakers include Dan A. Kimball, President of Aerojet-General Corp. and ex-Secretary of the Navy; Dr. Clifford C. Furnas, former Assistant Secretary of Defense, R&D; Dr. John P. Hagen, in charge of the Earth Satellite Program; Dr. Ernst Stuhlinger, Research Chief, Army Ballistic Missile Agency who helped develop the V-2,

DR. ERNST STUHLINGER

Maj. Gen. Dan C. Ogle, Surgeon General of the Air Force, F. L. LaQue, Vice President, International Nickel Co. and m/r's managing editor, Erik Bergaust, who will compare the missile science of Russia and the U.S.



Says SRI in the conference announcement: "Glamorous-sounding—even fantastic—missiles and space travel are rapidly assuming down-to-earth importance for the businessman who is, necessarily, concerned with practicality." Meeting takes place in Birmingham, Ala.

New Missile Camera

Bell & Howell has unveiled a new missile-scoring camera pod being built under Navy contract to provide an airborne record of missile accuracy in hits and misses.

Unit is built for mounting on the wingtips of target drones, pilotless planes or larger missiles and contains four 16 mm high-speed motion picture cameras. With one pod on each wingtip, the eight cameras are mounted to give complete spherical coverage as a missile approaches the target drone.

According to B&H, the system permits missile scoring at speeds up to Mach .95 and altitudes from 5,000 to 50,000 ft. A 200-foot film capacity is said to handle up to four missile passes.

But this is the age of

LIQUID OXYGEN

You can produce your own liquid oxygen with a Supairco plant, available in sizes up to 25 tons per day, with provisions for production of liquid nitrogen and argon as additional products.

Refrigeration is provided by a slow speed, heavy duty, single stage expansion engine.

High efficiency is attained in these plants through the use of a time proved cycle of our own design, the result of a quarter century of experience in the low temperature field.

Catalog on request.

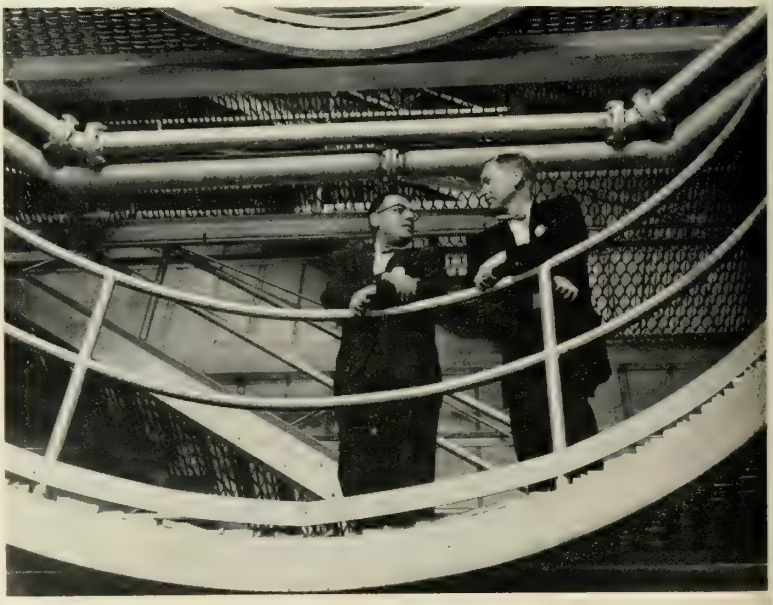
Metal Congress Tells of New Materials

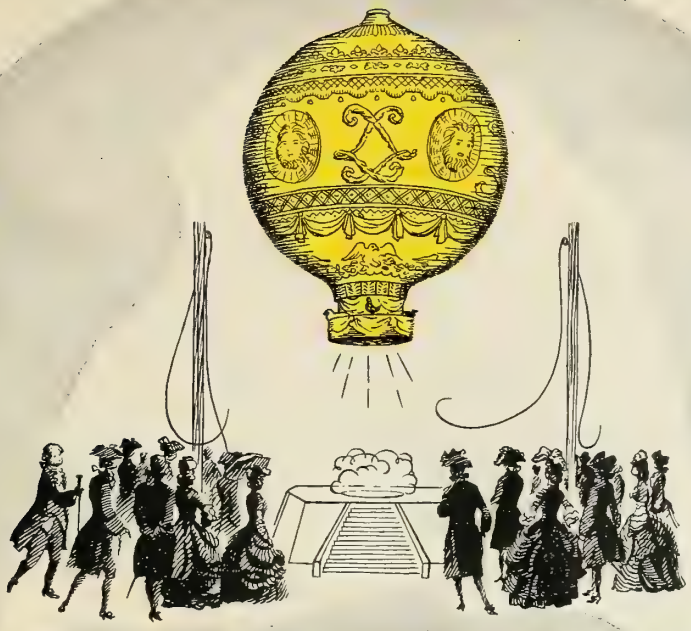
Materials and processes for missile applications were given much attention at the 10th Western Metal Congress of the American Society for Metals held in Los Angeles, California.

Titanium held the metals spotlight as the Metals Engineering Institute of the ASM programmed a special 5-day conference devoted exclusively to this subject during which time titanium was declared to have "arrived" as a bona-fide missile material, and increasing demands for titanium reflected its general acceptance.



Despite increased use of titanium and titanium alloys, it was pointed out the material is no structural panacea for temperature problems encountered in missile flight above Mach 4, the point at which present titanium and its alloys become ineffective. If some method of cooling can be developed to maintain speed temperatures below those encountered at Mach 4, titanium may be used to an even greater extent. As with any material of recent development, the problem of applying it to today's designs must be solved before creating future designs based on the material's properties.

The economy of titanium in certain missile applications was declared a difficult decision, as the considerable cost expended for the weight savings gained must be balanced against the purpose of the missile. Until such time as titanium is reduced below its present cost level and new fabrication techniques are developed, designers must incorporate economy in their original concepts. Large and complicated forgings are a particular problem in titanium as forge shops do not have sufficient experience with the material. The only alternative is to machine the part from a solid billet, an extremely costly operation as the finished part may be no more than four per cent of the original billet weight of several hundred pounds.



Present titanium alloys were noted as posing still another problem when used in forgings where heat treatment is required of parts with large cross sections in order to obtain maximum strength. This process changes the characteristics of the alloys sufficiently to make titanium's weight saving advantages open to question.

A discussion of titanium extrusions, as used in some current missiles, described the successful integration of the extrusions with titanium webs in box-beam construction by careful placement of rivets at the end of spotweld runs to minimize titanium's low peel strength. It is also possible to use the CHEM-MILL process to reduce web thickness overall and leave areas of greater thickness for large, load-carrying spotwelds.

Some problems of titanium may be averted temporarily by designing "around" them until a permanent solu-

Proof of progress in intercontinental ballistic missile development is in this fuel tank pressure test facility for the ATLAS recently completed at the San Diego plant of Convair Division, General Dynamics Corp. Chief engineer Mortimer Rosenbaum, left, inspects with J. R. Dempsey, Convair-Astronautics Division Manager.

Globe Aerostatique . . . 1783

Montgolfier's vanguard project

A sheep, a duck, a rooster—the first payload carried aloft for atmospheric research. Louis XVI, his queen and his court, were astonished witnesses as Joseph Montgolfier's smoke-filled balloon rose in majesty 1500 feet over Versailles. The passengers? unharmed (except the rooster, kicked by the sheep).

Project Vanguard, 1957, is an equally momentous "first"—an attempt to place a 21-pound satellite in an orbit 300 miles up. Aerojet-General, designer-builder of the famed Aerobee-Hi, will supply vital second-stage propulsion systems for Vanguard launchings during the International Geophysical Year.

missiles and rockets

tion is developed, it was declared. One of these is the relatively large minimum bend radii tolerated by existing titanium alloys, with new alloys expected to require an even larger radii and increasing the weight of the formed part. To anticipate this, new techniques such as creep-forming and hot forming are undergoing further study. Titanium alloy (6AL-4V) sheet is being formed successfully by the use of resistance heating and ceramic lubricants, but contamination and distortion are still critical in heat treatment of light gage sheets. Machined extrusions and welded angles are being used also to overcome forming problems.

Both resistance and fusion welding were credited with taking an ever-increasing part in missile applications of titanium, but the problem of providing an inert gas shielding during welding demands the component be designed with both sides of the weld accessible during fabrication. The accuracy of long resistance welding times, required in some applications, has been improved by incorporation of digital counting systems based on the British-developed Dekatron, a cold-cathode counting tube.

Titanium Users Cautioned

Titanium users were cautioned that although titanium has an unusual weld joint efficiency, only a few of the available titanium alloys are acceptable in welded structures for missile applications, and welding techniques should be rigidly controlled as no satisfactory non-destructive test of weld quality has been developed.

Tests of welded titanium were described as indicating welded joints of pure titanium and alloys containing primarily alpha stabilizing elements are not adversely affected by high temperature aging, but welded joints of alloys containing primarily beta stabilizing elements are extremely adversely affected by the same conditions.

The application of titanium in missile cooling tubes and heat exchangers was cited as an example of brazed components, although it was admitted that all problems in brazing titanium had not been solved.

The phenomenon of "creep," or flow of metal under heat and stress, was charged with being a principal factor limiting the use of titanium in missiles. Two of the newer titanium alloys containing aluminum, 6A1-4V and 5A1-2.5Sn, were said to have more creep resistance than eight per cent manganese titanium alloy, but exact data has not yet been determined to afford full application of these materials. Special equipment is being developed to obtain short-time, high-speed, high-temperature "creep" data by resistance heating at rapid rates and recording the results with special extensometers.

The problems of thermal expansion of titanium and titanium alloys were considered to present the designer with no more difficulties than any other material or material combination.

One property of titanium and its alloys detrimental to missile electronic application was described as its low electrical conductivity. When operating conditions rule out the use of any other structural materials because of weight and heat resistance requirements, titanium may be plated with a precious metal of high conductivity at little increase in cost or weight.

In spite of many excellent characteristics, titanium and its alloys were again described as not being the best possible materials for missiles from a structural-stress basis. This was attributed to the many types of load factors under which a missile component may be required to operate, and the many forms or shapes in which it may be used. However, work is continuing on the material efficiency curves for newer alloys which may be heat treated to

higher strength levels, and it is expected the new curves will be considerably higher than those of the much-in-use eight per cent manganese titanium alloy.

Several papers presented to ASM members dealt with progress in methods to determine mechanical properties of structural materials as applied to missiles. Nearly all outlined the rapid heat, rapid strain rate, and short temperature holding time approach to their investigations.

Molybdenum-Titanium Alloy Strong at High Temperatures

Other materials discussed briefly in relation to their missile applications were a molybdenum-base alloy containing .5 per cent titanium, which is claimed to have a higher useful strength at temperatures over 1600°F than any other presently known material, and precipitation hardening stainless steels.

Liquid propelled aircraft rockets were given a boost in a paper presented by Walter S. Tenner and Paul T. Barnes of the Naval Ordnance Test Station. Described as a "5-in., high-velocity, unguided, air-to-air rocket, the LAR (Liquid Aircraft Rocket) is propelled by liquid bi-propellants, although a solid propellant commonly is used in small rockets."

"The performance of liquid rocket propellants," Tenner said, "has many advantages over that of solid propellant rockets. The principal disadvantages are problems of 'hardware' and assembly.

"Since the originally used mechanical joints were unsatisfactory, welded joints were developed for some areas.

"A program was then initiated to determine the feasibility of welding the entire missile. Early tests indicated the use of an automatic welding process would be necessary to attain the desired results.

"Prototype welded missiles were fabricated and fired successfully."

The LAR is in the pilot production stage and, with simplified hardware assembled by welding, is claimed to be competitive in cost with solid-propellant rockets. Its performance was declared to be "outstanding."

Non-destructive testing was the subject of another large group of papers in which the use of X-ray, eddy currents, ultrasonic flaw evaluation, magnetic particle inspection, isotopic examination, fluorescent penetrants, and nuclear studies were described as finding wide application in the missile and rocket field.

RIAS Wants Sphere 2000 Miles in Space

RIAS, Inc., a subsidiary of The Glenn L. Martin Co., last month proposed firing a recoverable 150-pound sphere 2000 miles out into space with the idea of using emulsion sheets for measuring cosmic energy in free space. Basic proposal consists of stripping a vehicle like *Vanguard* of all guidance and special satellite launching gear and shooting it straight up.

That way, Martin designers W. J. Benckert and R. T. Patterson figure, both payload and terminal altitude could be materially increased over that hoped for from *Vanguard.*

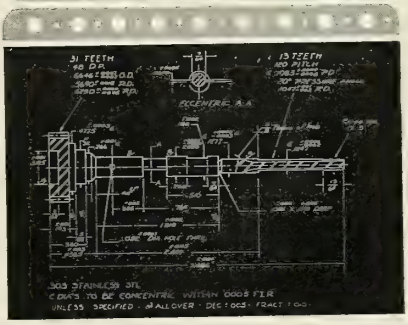
Of the total 150-pound sphere, only about 50 pounds would be available for scientific payload. The rest would consist of an outer shell to take the brunt of reentry. Presumably it would be made of a material that would dissipate heat by melting and/or sublimation during initial reentry and deceleration. In addition the sphere would contain a parachute (or series of them) for lowering the payload to earth unharmed. It would also include a radio beacon for locating it on the ground.

It's estimated that it would spend 40 minutes above the atmosphere and attain a top speed of 13,000 miles per hour on reentry. Analysis of the emulsion sheets to determine the nature of primary cosmic radiation in space would, Martin estimates, require several months of work by a hundred or more research workers.

This is a hypothetical proposal by Martin, since no contract now exists for making the attempt.

Bristol Develops Practical Missile

Bristol Aircraft Ltd. reports the development of "an entirely practical" missile (probably a SAM, according to the Society of British Aircraft Constructors). Bristol made this statement when the Ministry of Supply authorized the release of a photograph of an early Bristol supersonic vehicle known as *Bobbin.* Now some years old, this device was developed for test work on guided weapons and on Bristol's *Thor* ramjet engine.



Bristol has released a limited amount of information on the testing of *Bobbin.* It had a long, spiked nose which stuck into the ground on landing. Supersonic parachutes, developed by the Irving Air Chute of Great Britain and G. Q. Parachute companies, slowed *Bobbin* down from very high speeds so that when it landed on its nose spike, it was virtually undamaged.

The parachutes themselves underwent novel tests over Salisbury Plain, in Wiltshire, before being fitted to *Bobbin.* A dummy test vehicle was dropped from a *Canberra* at very high altitude and accelerated in free fall to well above the speed of sound—producing a sizeable sonic bang. Six ribbon parachutes were released by time switch before, their work done, they were jettisoned automatically. In falling away, they drew out a 30 ft. nylon parachute which lowered the test vehicle gently to the ground. In this way, *Bobbin* became the first British-designed recoverable test vehicle.

Tests to design and manufacture the long nose spike were performed by using a dummy vehicle which was dropped vertically from a crane. Decelerometers and high-speed cameras measured the rate of impact. To establish how the nose spike would react to various types of terrain, half-scale models of the test vehicle were dropped from a helicopter over the Woomera range in Australia.

North American's X-10 Ends Successful Test

ERRONEOUSLY LISTED as dead, North American Aviation's *Navaho* is still a very much alive project. While the contract has been terminated on the intermediate XSM-64, the basic contract for a successor air-breather to the Northrop *Snark* continues in force (see Industry Highlights, p. 144). Meanwhile the program has not been without its benefits.

NAA's retrievable X-10 has been applauded by the Air Force as an "invaluable source of important data." Announcement that the missile-on-wheels had wound up a series of successful test flights was made early this year. It was flown hundreds of miles at supersonic speeds under full automatic control to prove out its design and guidance systems.

The X-10 is powered by two turbojet engines. Its landing gear makes it recoverable for repeated use.

This vehicle is part of the SM-64 *Navaho* weapons system research and development program. Earlier the 14-foot *Nativ*, a single ballistic missile, was successfully tested.

X-10 lands smoothly—coming in with nose high, easy touch-down. Note position of canard stabilizer. X-10 has been applauded by Air Force as "invaluable source of important data."

The *Navaho* weapons systems program goes back to 1945. *Navaho* is one of the most controversial missiles of the day. Big question mark: How good is an aerodynamic intercontinental missile in tomorrow's hypersonic age? Another one: Is the *Navaho* a competitor of the *Snark* or vice versa and can we afford both? Ballistic missile enthusiasts may think there is no need for a *Navaho* but General Curtis LeMay seems to think differently. He wants a long-range missile while waiting for the ICBM.

Now in advanced stages of development, *Navaho* flight testing was undertaken at the USAF Missile Test Center, Florida.

Design and manufacture of the *Navaho* guidance and control systems is the responsibility of North American's Autonetics Division. A third division, Rocketdyne, builds rocket engines for the missile, which will be rocket-boosted to flying speed and then powered by ramjets.

Work on the *Navaho* has been underway for some time in North American's Missile and Control Equipment operations (MACE) at Downey, Calif. MACE operations involve major phases of missile airframe design, rocket engine propulsion, automatic guidance and control equipment. North American says its MACE technical force "is being expanded greatly."

NAA's Missile Development Division started in 1946 with a few men working in a corner of the company's Los Angeles plant. Today the Missile Development Division has grown to about 7,000 workers.

The company began experimental work late in 1947 after completion of studies in airframe, and propulsion. These included possible nuclear power and automatic guidance and control systems. In May, 1948 the first research missile was sent up at Holloman Air Force Base, N. M. This was the *Nativ* and eight of these were built and flown. The staff soon outgrew its Los Angeles quarters and moved to its present location in Downey.

In 1950 the SM-64 *Navaho* missile project was born.

Growing out of NAA's Missile Development Division were: The Autonetics Division, Atomics International Division and the Rocketdyne Division. The four divisions today employ nearly 25,000 persons and have earned for North Amercan the reputation as "the country's best integrated and probably biggest missile research organization."+

more NEW SILICON SEMICONDUCTOR DEVICES

from Hoffman Leader in Industry

10 Watt SILICON DIFFUSED JUNCTION VOLTAGE REGULATORS

for VOLTAGE CONTROL purposes in aircraft, missiles, land vehicles, and other equipment

★ Extremely low dynamic resistance in zener region provides stable DC source regardless of severe line voltage changes.
★ Broad choice of low voltage values makes them especially suitable for transistorized circuitry.
★ Excellent long-time stability.

Characteristics: Available with tolerances of 10% and 5% at zener voltages between 10 volts and 100 volts; maximum dissipation 10 watts for 25°C case temperature; typical dynamic resistance — 1 ohm for unit with 20 zener volts at 500 mA.

HIGH VOLTAGE, Medium Power Silicon DIFFUSED JUNCTION RECTIFIERS

Combining PIV to 1000 VOLTS and I_o to 350 mA with firm delivery schedules

★ Maximum diameter only 0.220 inches
★ Rated for operation in free air — no heat sink required
★ Choice of axial or single ended leads

Many full-wave, bridge and center-tapped assemblies of these rectifiers are available in this sturdy package.

Type	Max. Recurrent Inverse Working Voltage — e_b (Volts)	Min. Zener (breakdown) Voltage — E_Z (Volts) (Note 1)	Max. RMS Voltage (Volts)	25°C Ambient Max. Avg. Forward Current—I_o (Milliamps.)	Max. Avg. Forward Voltage at I_o=500 mA (Volts)	125°C Ambient Max. Avg. Forward Current (Milliamps.)

Rocket Trends

By Erik Bergaust

Even the experts seem to ignore what's wrong with our intermediate-range ballistic missile program. Certainly, the problem is not the otherwise harmful interservice battle between the Air Force and the Army. However, the seemingly ignorant high-echelon orders and rules on roles and missions, that have caused this Army/Air Force controversy, will determine something more important by far. They will determine if we will win or lose the race with our potential enemies.

It has been our privilege to discuss this serious problem with top military leaders. We have interviewed secretaries, generals and admirals for hours and hours—and have traveled thousands of miles to get the true story—and have found that the Air Force is doing a terrific job on the most important of our current missiles, the ICBM. In fact, the prototype of the *Atlas* ICBM is being readied now for its maiden flight. (It might have flown by the time this issue of m/r reaches its readers. *More than a dozen Russian submarines were spotted off the coast of Florida as m/r went to press.* Navy blimps are busy watching the unwanted visitors.) Could it be this accomplishment is based on the fact that the ICBM program has never been hampered by interservice rivalry? Apparently the *Atlas* ICBM now is in a more advanced stage than the *Thor* IRBM. Likewise, we have found there's no doubt about the Army's IRBM capability. The Army's ballistic missile capability is so excellent it is possible that they will demonstrate it by sending a space satellite into an orbit around the earth early this summer.

We have discussed the ballistic missile program with senators and congressmen. Says Sen. John D. Sparkman: "Let the Army develop the *Jupiter*, the Air Force the *Thor* and the Navy the *Polaris*. In a future war, we'll need all of them." Certainly, the Air Force should have an IRBM. On the other hand, it is utterly ridiculous to knock out the Army, because the Army has a *requirement* for this kind of *long-range artillery* if it is to stand up against Russia in a future atomic war.

This is why we must have a full-fledged IRBM program, and we cannot afford to cut it short now. Because the real problem is Russia. What are we doing about the fact that the Communists launched a 650-mile operational ballistic missile (the *Comet*) two years ago? From submarines! Are we overlooking that the Russians now have operational IRBM's? And that their missile subs have been spotted off our coasts? When will we wake up to reality and comprehend that the Russians carried out a full-fledged missile research and development program with intense eagerness (from 1945 to 1950) before we even started to think of any accelerated high-punch missile projects? Who are the military leaders in this country who dare kill any ballistic missile project, as long as only a handful of *Thor* and *Jupiter* prototypes have been built, and it takes at least one year to get an evaluation, and two or three to get them into production?

That's what is wrong with our IRBM program. The fact that we're trailing Russia—dangerously. This is the issue. But it appears our defense leaders do not want to understand this. And another thing: this absolutely fantastic idea that has been played in the press lately, that this country is about to provide Britain and possibly France with intermediate-range ballistic missiles! Let's stop fooling the public. We don't have any such missiles. They are two or three years away. We might get them sooner if the services were given the go-ahead on a sound competitive basis—without being hampered by morale-breaking, nerve-racking policies. (We have learned reliably that the "give-away" IRBM will be a *Thor* with *Jupiter* guidance.) Such policies never serve any useful purpose. And certainly not now, when the most important of all battles is being fought: the technological race between this country and Russia.

missiles and rocke

Washington Spotlight

By Henry T. Simmons

Final determination of the fate of the North American *Navaho* ramjet missile will be made by the Air Force next fall. As of now, it appears that two principal conditions must be met if the intercontinental weapon is to go into large-scale production: It must make an excellent showing during current tests at Patrick AFB, Fla., and unexpected roadblocks must crop up in the ballistic missile development program. Furthermore, they must be serious difficulties—bad enough to delay introduction of the ICBM three years or more beyond the operational date expected for the *Navaho*. Any lesser delay would probably persuade the USAF to step up production of the Northrop turbojet *Snark*.

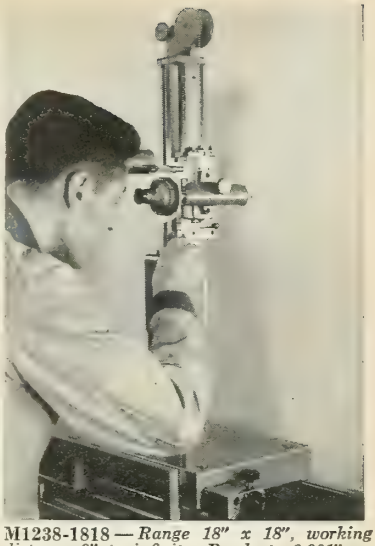
•

Even should everything favor increased support of the *Navaho*, there remains the knotty problem of where to find the money. If really serious troubles hamper the ICBM, of course, funds can be withdrawn from that program and applied to *Navaho*. But the North American weapon will still be just one of many projects clamoring for money. Probably its most important competitor will be the WS-110A intercontinental chemical bomber projected by the USAF as a replacement for the B-52. NAA and Boeing are expected to submit their WS-110A entries about June, with an Air Force evaluation several months later. Should really tough problems arise in the ICBM program, the Air Force may be more inclined to fall back on a traditional manned bomber concept rather than strike out into new and unfamiliar production, maintenance and operational territory with the *Navaho*.

•

The Air Force is still studying the failure of the *Thor* IRBM on its maiden flight at Patrick early this year. The trouble was apparently caused by a recalcitrant valve in the engine starting system. Probably because of an explosion which occurred when the liquid oxygen came into contact with an impurity in the valve, the valve itself failed to close tightly. This permitted a portion of the LOX which should have gone to the engine to recirculate, thus starving the combustion process so that the rocket sagged back to the ground. The airmen hope to duplicate the exact circumstances of the accident.

•



Army procurement of guided missiles is heading upward even faster than in the Air Force. The soldiers expect 50% of their total procurement funds will go for birds in fiscal 1958, beginning next July 1, compared with 23% just two years ago.

•

Although the existence of a guided missile called the *Corvus* has been known for more than two years, it was not until last month that the name could be nailed to a specific project. It seems that a $16 million Navy contract awarded Temco in January provides for design and development of the weapon. *Corvus* (Latin for Crow) is a long-range air-to-ground missile to be carried by a brand new Navy attack fighter for which a competition has just been established. It is believed the Temco weapon is a descendant of Fairchild's *Lark* research missile.

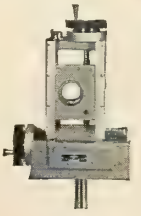
•

Rep. Carl Vinson (D-Ga.) has scotched chances for an early hearing on the *Thor-Jupiter* by his House Armed Services Committee. Rep. George Huddleston, Jr., (D-Ala.) had urged a secret hearing on the IRBM program, but Chairman Vinson said it would not be wise. "I am mindful of the pending court martial action which has a direct bearing on this matter and I feel this committee must do nothing that could prejudice the court martial in any way," he wrote.

M1238-1818 — *Range 18" x 18", working distance 9" to infinity. Reads to 0.001" up to 24" working distance. Protractor ocular reads to 3 minutes of arc. Image is erect.*

Cut inspection time in half

with new Gaertner Coordinate Cathetometers



These convenient, reliable optical instruments permit making precise coordinate measurements in a vertical plane. The two dimensions are measured with one setting, object does not have to be rotated. Inspection time is cut in half and resetting errors eliminated.

Versatile Gaertner Coordinate Cathetometers are ideally suited for precision measurements on large objects; also objects or points in recessed, remote, or inaccessible locations. Applications include measuring jet engine sections, complicated castings, printed circuits, bolt holes and bosses on large piece parts, traces on cathode ray tubes, etc.

Because these are optical rather than mechanical measuring instruments, you make non-destructive measurements without contact, distortion, or concern about pressure being applied to the object when making a setting. Instruments available in English or Metric system.

M1236-46— Horizontal range 6", vertical range 4". Reads to 0.0001", working distance 5" to infinity.

M1236-22— Range 2" x 2", reads to 0.0001". Working distance 5" to infinity. Shown with 19 mm mounting rod, and without telemicroscope. Instrument permits precise coordinate movement of other objects such as photo cells, probes, etc., in place of telemicroscope.

missiles and rockets

MAGAZINE OF WORLD ASTRONAUTICS

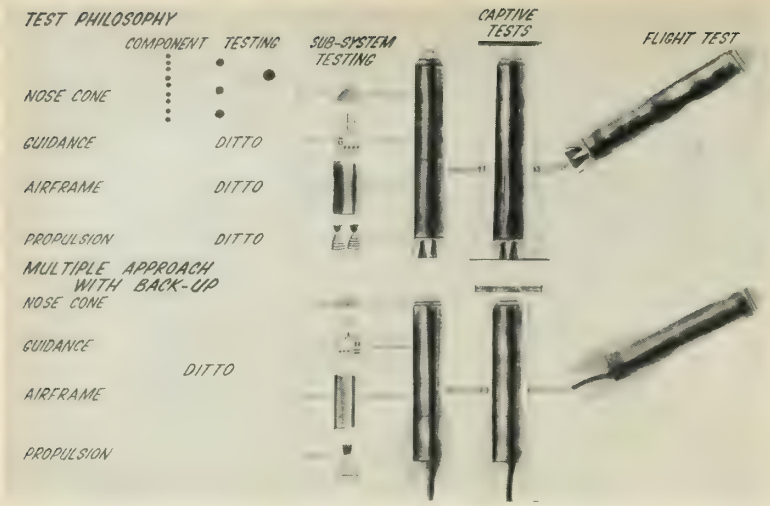
m/r exclusive:

USAF's Long-Range Missile Program

IT HAPPENED in the early evening of September 6, 1944. People of Chiswick-on-Thames, London, had just finished their evening meal. At 6:38 this evening, at Wassenaar, on the outskirts of The Hague, Netherlands, the first military rocket capable of approaching a predetermined target at a speed greater than sound and with no advance warning was launched. It was an awesome weapon, forty six feet in length, and weighing 2,200 pounds. Its speed was 3,500 miles per hour, and at the height of its trajectory it reached a point 50 miles above the surface of the earth. It was an all-weather weapon, and most fearsome of all, there were no counter-measures against it. The effect was devastating. The people of Chiswick-on-Thames felt it. For this was the first "target" to be hit by a liquid-propellant ballistic missile.

The dramatic launching of the first rocket attack in history was born of desperation on the part of Hitler. Following early and easy victories in Poland and France, Germany suffered defeat in its efforts to conquer England by air attacks. This set-back was followed by collapse of the German invasion of Russia. Clearly, something desperate was necessary, and the rocket seemed to be the answer. Following the initial rocket offensive 26 additional missiles were directed toward London during the next ten days. Between September 1944 and March 1945, approximately 1,500 V-2 rockets were showered on England.

Thus, comments after the war by leading military figures, that such an offensive, if perfected in the early days of the war, could well have defeated the Allies. General Eisenhower, writing in his book, Crusade in Europe, stated "It seemed likely that if the German had succeeded in perfecting and using these new weapons earlier than he did, our invasion of Europe would have proved exceedingly difficult, perhaps impossible. I feel sure that if he had succeeded in using these weapons over a six month period, and particularly if they had made the Porthsmouth-Southampton area one of their principal targets, 'Overlord,' (codename for the planned cross-Channel invasion of France), might have been written off."



This article on the history and development of long-range ballistic missiles, and the role our Air Force plays in the important ballistic missile race with Russia, outlines the philosophies behind long-range missile weapon systems as well as some of their psychological effects on our society. The article was prepared by m/r managing editor, Erik Bergaust, and Vincent B. Hackett, Field Engineer, Telecomputing Corporation.

In the years immediately preceding the outbreak of war, one of the most closely guarded secrets in Germany was the experimental work being done in the field of ballistic rockets.

Early in 1930 General, then Captain, Walter Dornberger, Dr. Ernst Steinhoff and Dr. Wernher von Braun were busily engaged experimenting with the theory of such missiles for the German Army Ordnance Corps. In March of 1936 Colonel-General Werner von Fritsch, Supreme Commander of the Army, was persuaded by Dornberger and von Braun to visit the early experimental station in Kummersdorf to inspect the work under way. This visit resulted in an allocation of funds for future experiments, and a decision to approve von Braun's plan to move all operations to an isolated spot, previously selected by von Braun, on the coast of the Baltic Sea. This occurred in 1937. The new location, Peenemünde, was destined to become a source of prime interest to the British High Command before the war was brought to an end.

Hitler was showing enthusiasm over the progress developed in the missile program. In June 1943 he visited Peenemünde to observe first hand what might be expected. Already desperate, he visualized the possibility of opening a decisive attack on England by a new and terrifying vengeance weapon, which might serve to prevent any plans of crossing the Channel into France.

He left Peenemünde determined on all-out effort as a new and final effort to create panic among the Allies. Evidence of this desperation is afforded by his statement to German military associates on June 10th that, if the

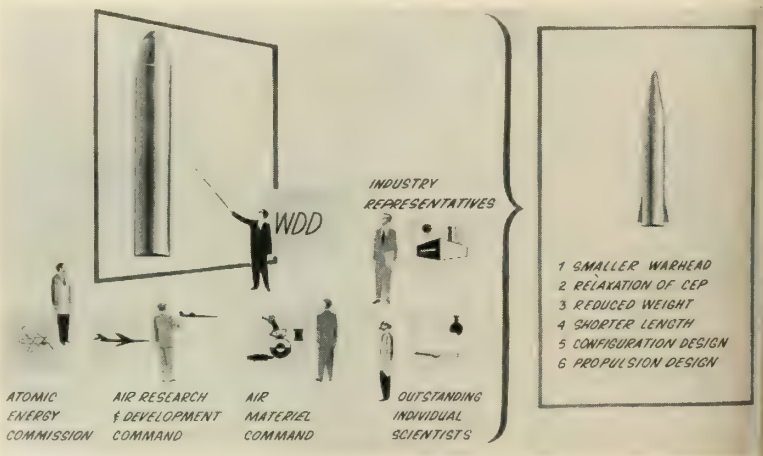
Western Development Division's test philosophy for the two intercontinental ballistic missiles Atlas and Titan. Convair's Atlas is being readied at Patrick AFB for its maiden flight test; Martin's Titan—which got under way later than the Atlas—may fly at the end of this year.

German forces would hold on for a short time longer, London would be razed and England would be forced to surrender. He gave the date of October 30th as the date for the beginning of such attacks. It is said that Hitler ordered 30,000 rockets for immediate production, thereby indicating the degree of confidence in the new weapon. It was an unrealistic program. One thing was evident. Hitler planned to rain rockets on London in a desperate effort to bring England to her knees. England's duty was clear—crush the new menace at its origin, Peenemünde.

On the night of August 17th, 571 heavy RAF bombers struck from a level of eight thousand feet. This sorty resulted in the loss of forty aircraft, but the results were worth the loss. Drawings due to be issued to the workshops were burned, 715 personnel were killed, including Dr. Thiel, the commanding military officer.

Reports from Britain indicate that over 1,000 V-2's alone fell in and near London over a period of seven months. The number of homes and buildings destroyed ran into the tens of thousands. Only due to the fact that the Canadians in March 1945 captured the launching sites in Holland was much greater damage and loss of life prevented. There is no record that a single V-2 was intercepted or shot down once under way.

According to Dornberger, 9,300 V-1's were fired day and night against England—about 6,000 reached the English coast—4,300 V-2's were operationally directed against England and over 2,100 against other targets. The last V-2 fired was on March 27, 1945 at 4:45, and its target was Orpington in Kent. This last rocket was the 1,115th to fall on England—Casualties for the entire period of firing was 2,511 killed; 5,869 seriously wounded in London, and 213 killed and 598 seriously wounded elsewhere, according to Dornberger.



The history of the V-2, the world's first ballistic missile weapon, and the statistics on death and destruction caused by this weapon, clearly indicated that this kind of missile was here to stay—that highly advanced ballistic missiles would be included in any modern defense system. As a matter of fact, the art of missile science has advanced so rapidly since the days of the V-2 that 50% of the USAF budget will go for missiles within the next two or three years. And Russia puts an equally great emphasis on these weapons. There are, in fact, indications that the Russians might be ahead of us in many phases of missile development. Some of her ballistic missiles have already reached the production stage . . .

America Takes Advantage

Project "Paper Clip" has meant a lot to American technological and scientific advancement. This was the program under which top notch German scientists were taken to this country. Ballistic missile know-how was brought to the United States and the US Army could establish an important ballistic missile program. American industry, thus, became familiar with the art. The need for missile engineers turned into a boom with more need for specialized training and education. During the last 12 years a whole separate industry has emerged from the early backyard experiments that took place at White Sands with captured V-2s.

In 1946 the Air Force assigned to Convair a research contract for Project MX-774, in a sense the predecessor to the *Atlas*. But the early project was cancelled out one year later, in 1947, because of the Defense Department's economy "review" of this and other seemingly "unnecessary" weapon system concepts. Of course, the Air Force knew only too well that this was dangerous. They watched how the Army proved the feasibility of ballistic rockets. They knew the Russians were working on long-range ballistic missiles. They knew it was necessary to carry out an intercontinental ballistic research and development program. Obviously, the Air Force would have to become the service in charge and control over long-range missiles, eventually. This weapons concept was nothing but strategic bombing.

In 1951 the Air Force came into the act again. And this time top Air Force planners played their cards so

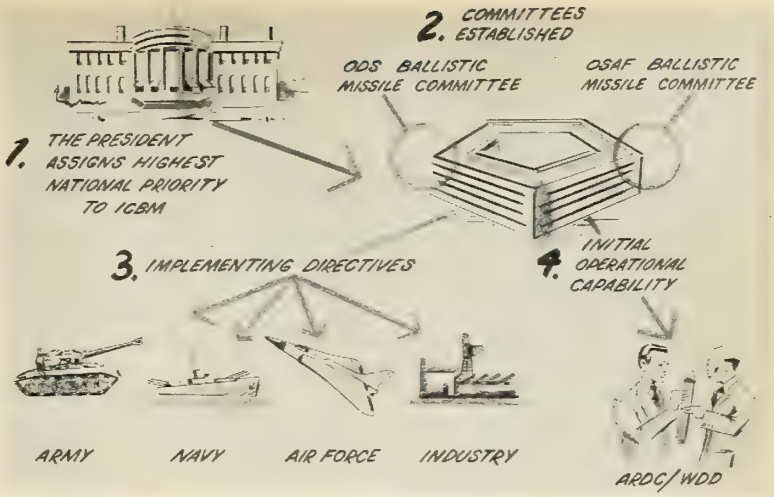
The Air Force' ICBM programs represent a great industrial challenge. This illustration shows the military and civilian elements involved.

that it would never again be possible to kill any phase of the projected ballistic missile program.

Thermo-Nuclear Break-through

The Air Force ballistic missile program encompasses the largest concentration of men, money and materiel on a science-industry military basis that has ever been achieved. The end product required—an operational intercontinental ballistic missile at an early date.

The thermonuclear break-through in 1952-1953 was a major break, according to WDD Chief, General Bernard A. Schriever. The possibility of high yields in reasonable packages meant that accuracy requirements could be relaxed, that it was now technically possible to develop a reliable guidance system, and that the overall weight of the missile could be considerably lessened.



In August 1954, the Western Development Division of Headquarters ARDC was established in Inglewood, California. WDD was to have responsibility and authority over all aspects of the program with the specific purpose of reorienting and accelerating the ICBM program in order to achieve the earliest possible operational capability.

By January of 1956, the Air Force Ballistic Missile Program had been expanded to include the IRBM *Thor*. The ICBM program already had under development all the subsystems such as propulsion, guidance and nose cone, which were required for the *Thor*. Therefore, only the Douglas Aircraft Company, which has the airframe, assembly and test responsibility, was added to the list of industry contractors. Tapping the ICBM program provided a special opportunity for maximum saving in development time and money.

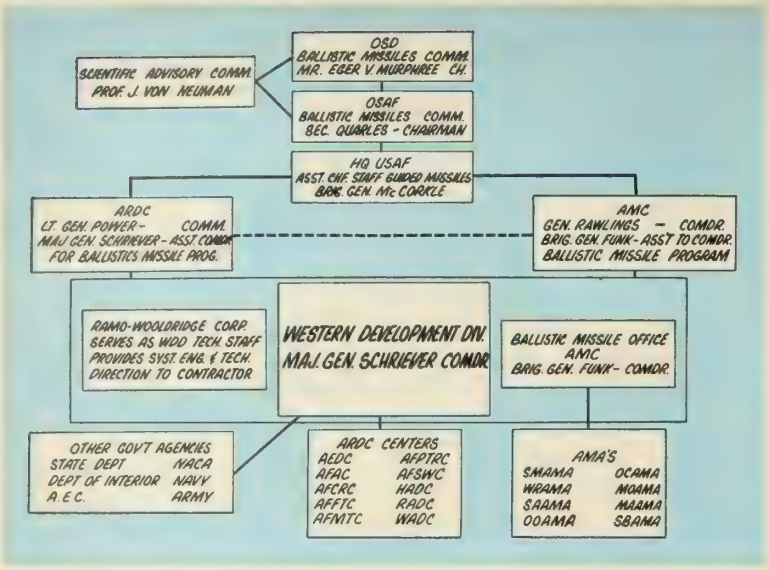
The establishment of WDD by the Air Force was indeed a unique and important management step. It marked the first time that the Air Force would retain full and complete management responsibility over a major development effort.

The concurrent development and production of the Air Force's Ballistic Missile Program under the management of an overall team is an integrated approach without precedent. The program is on schedule. Milestones are being met and the WDD Chief is confident that they will continue to be met.

The Air Force firmly believes in the policy of utilizing the demonstrable effectiveness of all elements of U.S. science and industry. Accordingly, the strongest scientific - industrial - military team possible has been assembled by the Air Force in all fields of ballistic missile requirements in support of this, the nation's highest priority program.

The President of the United States has assigned top national priority to the ICBM program —overall simplicity for conducting the program is emphasized.

Without this philosophy and without the wholehearted response of science and industry, the task could not be accomplished.



USAF Missile Management

Three elements are making up the total Air Force long-range missile systems organization management; first, the Western Development Division, which is part of Headquarters, Air Research and Development Command. WDD has the overall responsibility and authority for the program and supervision of the management complex. Secondly, the Ballistic Missile Office, which is part of Headquarters, Air Materiel Command, performs all the contracting activities of major contractors and administers the contracts.

The Ballistic Missile Office supports the operational activity in terms of maintaining supply records, procuring the necessary level of spare parts,

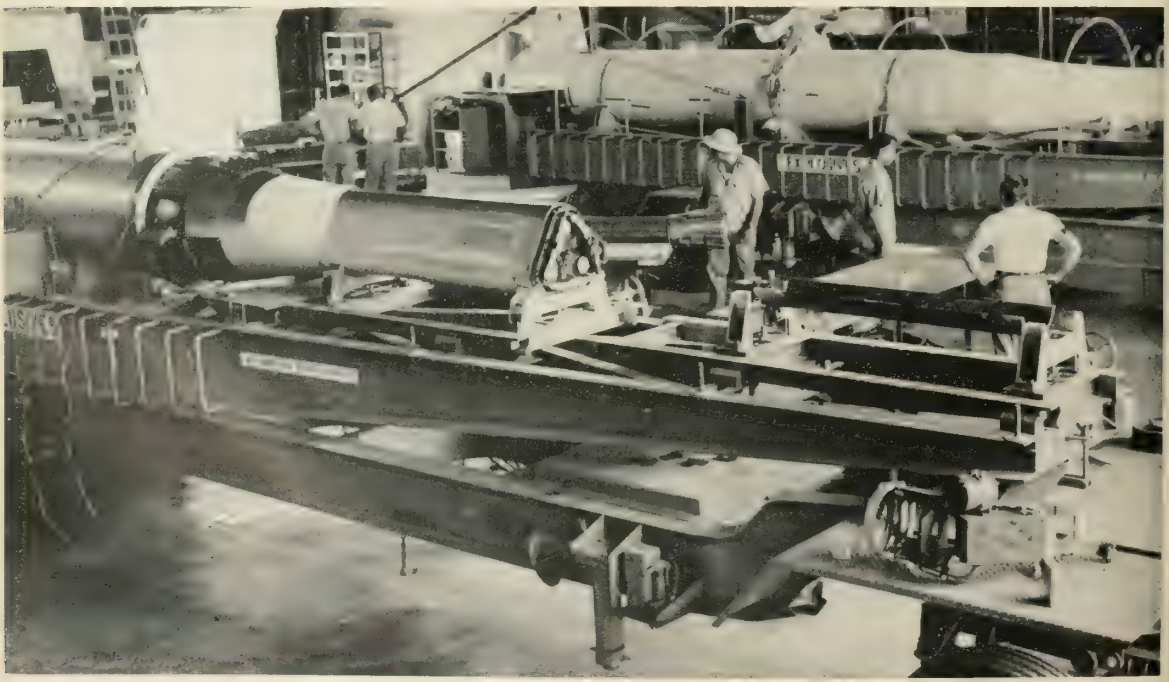
1957	US Starts Flight Test Program For IRBMs and ICBMs



Organizational chart showing the various functions and the jurisdiction pertaining to the Air Force long-range missile projects.

establishing maintenance procedures and affecting necessary transport of parts and missiles.

The third element is the Guided Missile Research Division of The Ramo-Wooldridge Corporation, which has the systems engineering responsibility. The Air Force has found it necessary to have a systems engineering manager to integrate the subsystems. For example, the same basic power plant that powers the *Thor* missile also provides the basic propulsion element for the *Atlas*. For the *Atlas* the Air Force uses a combination of engines, while a single engine is used in the *Thor*. From the standpoint of the thrust chamber and most of the basic plumbing and what goes with it, the engine is the same. The nose cone is being developed by General Electric and will be used both on the *Thor* and the *Atlas* in the early operational missile. Later on there will be different specification, but the approach under development will get the Air Force there quicker. In the guidance area Bell Telephone Laboratories has the radio inertial guidance system contract—this guidance system will be used both for the *Titan* and the *Thor*. Consequently, the Air Force has to centralize the technical direction of contractors to be sure the BTL system is compatible to both the *Thor* and the *Titan*. The Air Force could not delegate down to Martin and to Douglas; it needs an "umpire," because they will run into differences, naturally. For instance, one contractor will want something just a little bit different than the other one. That is why the Ramo-Wooldridge Corporation was called upon to monitor the program. So far, this has worked fine. And the Air Force actually is *ahead of schedule* on several of the evaluation and test phases of the ICBM program.

Certainly, the Air Force has come a long way. The Air Force and American industry have proved that practically any technological challenge can be met. Yet, many experts question whether we are so well off in comparison to Russia. But this might be a result of getting the program underway late, something which is dictated by

Two X-17 reentry test vehicles at Lockheed's facility at Patrick Air Force base being assembled on the strongbacks which will carry them to the launching pad. X-17 plays important role in the Air Force long-range missile research and development program.

politicians. The Air Force cannot be blamed for this.

Nevertheless, the Air Force has been pushing these programs hard, and we are now reaching the point when even Air Force spokesmen talk about using ICBM hardware for the purpose of sending rockets to the moon—as part of the ICBM training program for launching crews.

A Military Leader and Sound Industrial Planning

The Air Force's eagerness—from an early date—was inspired by General Bernard A. Schriever. He has been pushing the program hard—and being the born leader, he has truly built the backbone of the Air Force ballistic missile program. He is charged with the responsibility of keeping the Air Force on the right course, at the right speed —and well ahead of our potential enemies.

However, let us not forget that the Air Force Ballistic Missile Program is a typical American *industrial challenge,* and that the Ramo-Wooldridge Corporation, as program monitor and engineering manager, has contributed much to the advancement of the projects involved. R-W is actually a typical American firm—although its functions in the Ballistic Missile Program are unique.

The record of the company in this work, on behalf of the national defense effort, has been unusually good. One of the reasons — possibly — is that the Ramo-Wooldridge Corporation at its inception sought and succeeded in establishing a close liaison with Thompson Products, a typical American "big business" firm.

A measure of the importance which is given by Thompson Products to its affiliation with The Ramo-Wooldridge Corporation is the fact that under arrangements existing between the two companies, R-W has access to funds in excess of $20,000,000 to finance its operations and expansion requirements for the next few years.

The main areas of ICBM design and development include propulsion, airframe, staging, reentry and warhead. Air Force seeks to employ overall simplicity, standardizing engines, nose cones, warheds.

While control of the company is vested in the hands of its key employees, the assistance provided by Thompson Products is not limited to the extensive financial backing it provides. In addition, the business and industrial experience and services of this large organization are made freely available to Ramo-Wooldridge. The extent of the interest and assistance is indicated by the fact that the Chairman of the Board, President and two Vice-Presidents of Thompson Products serve on the nine man Ramo-Wooldridge Board of Directors, and give freely of their time to help the executives of the organization make certain that business matters are handled with an adequate level of professional competence. The relations between the two companies have been strengthened still further by the election of three of the officers of Ramo-Wooldridge to the Board of Directors of Thompson Products.

In summary, the ingredients that should provide The Ramo-Wooldridge Corporation with a high probability of remaining a stable ballistic missile program manager are: a field of activity characterized by a demand for competence far exceeding the supply, a staff organized around experienced men with an outstanding record of accomplishment in this field, and an unusual degree of business and financial soundness provided by the strong support of a large and stable company. ★

This illustration shows how the Air Force selects contractors for the long-range missile projects. While all prime contracts have been let long ago, thousands of subcontractors have become involved recently. Subcontracts are still being awarded.

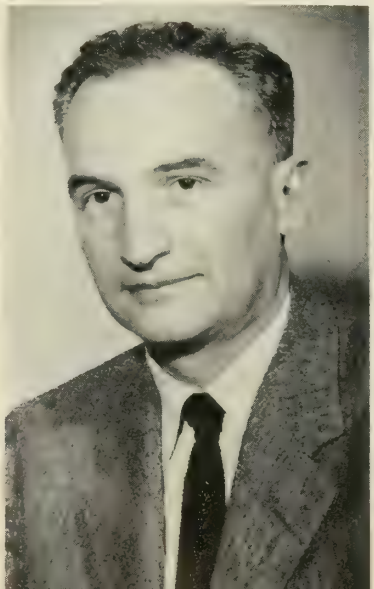
The Ramo-Wooldridge Story

THE ROLE OF The Ramo-Wooldridge Corporation in the Air Force ballistic missile program includes a number of functions under the heading of Systems Engineering and Technical Direction. To be more specific, these functions should be broken down into a group of tasks. One of them is to create an overall research and development plan; a plan that considers what the technical state of the ballistic missile art ought to accomplish to get consistency and a compatible compromise between what science says is possible, and what the military believes it needs.

Next, R-W translates that research and development plan into what one might call an *action plan* that considers what industry can do versus *time*. Selection of the most qualified industry for the myriad of important tasks connected with the ballistic missile program becomes a major consideration. Yet this cannot be done without consideration of the total facility problem.

Ramo-Wooldridge must, in effect, take the initiative for the technical side, and while working very closely with the Government, with the Air Force, and with industry, translate the R&D plan into an accompanying facility plan. All of these things must be done at once, and each feeds back on the other. It's the chicken and the egg problem again. A facility program must go along with an R&D plan and specify, for instance, so many test stands in certain locations near the engineers who are actually going to do the detailed development.

It is necessary for the systems engineer to see that such facilities are provided on schedule. So, the ideal thing then is to create an R&D plan with all its related and supporting annexes, a *facility plan* which considers military requirements, scientific fundamentals, industry know-how and facility acquisition.



At the same time, Ramo-Wooldridge must consider the backup programs. Where is the technical art closest to the limit of what you can be certain about? Ramo-Wooldridge cannot raise the question of whether something is fundamentally possible. They must create a plan which relates these things from the beginning, in such a way that one can have confidence that the whole project can be brought off. They can only be concerned with *how* to bring it off in the *shortest* time, by the best use of the nation's resources.

Indeed, Ramo-Wooldridge must decide reliabilities at various stages of the program: how far should the Air

Dr. Dean E. Wooldridge, President; Treasurer.

Dr. Simon Ramo, Executive VP, and Sec.

Force go with component testing; and when should the Air Force take on the expensive and more dangerous *systems test?* What will the Air Force *learn* from the initial systems test? Should the Air Force allocate *early testing* for the purpose of getting the team in shape; getting the whole proving ground proven out?

Basically, the Ramo-Wooldridge Corporation conducts research, development, and manufacturing operations in the field of electronic systems for commercial and military applications, and in the field of guided missiles. The company is organized around a central group of scientists, engineers, and administrators who are said to have unusual records of recent accomplishment in these fields.

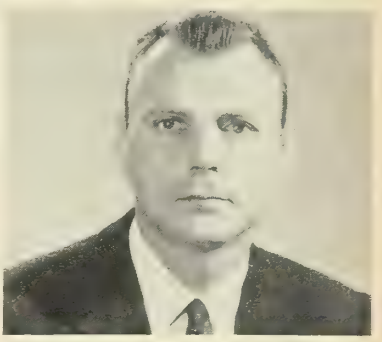
Both because of the national need and the inclination and experience of the key people, emphasis in the Ramo-Wooldridge Corporation is on the development of products containing *a high degree of scientific and engineering newness.* Every facet of the organization and the operational procedures are designed to fill the special needs of the scientist and engineer.

A certain amount of pioneering spirit is required of those who work together to help develop our big ballistic missiles. All of them enjoy the air of adventure, but most of them, particularly scientists and engineers, like to feel that the odds in favor of eventual success are fairly high. Combined with the probability that early affiliation with a fast-growing organization is likely to lead to a rapid increase in individual responsibility and reward, the result can make for a stimulating and fruitful career. This concept, in particular, applies to the ballistic missile program monitor, the Ramo Wooldridge Corporation.

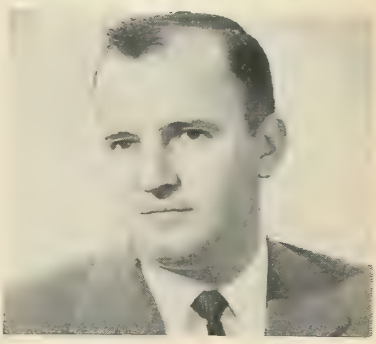
Major elements in any evaluation of ballistic missile prospects of this young company include (1) the general scope and promise of the field in which the company is engaged, (2) the competence of the organization relative to competition, and (3) the adequacy of the financial backing and business management. With respect to the first two points, there can be no doubt that there is a tremendous national need for greater competence in electronic systems analysis, engineering, and development. The Ramo-Wooldridge Corporation expects to maintain its reputation for competence in this field.

No matter how bright the promise seems, it is still easy for a young company to fail if it is not adequately financed, or if its business management is inept. Both of these contingencies have been guarded against by establishment of strong ties with Thompson Products, Inc., one of the soundest and most highly respected large companies in the United States. Thompson Products, with headquarters in Cleveland, Ohio, has served the automotive and aircraft industries for many years. In addition to an enviable growth record going back for many years, and a volume of business of several hundred million dollars a year, Thompson Products is known for its enlighted management policies, both with respect to personnel relations and operational techniques inside the company, and for its aggressiveness in the development of new fields of interest.

There is no field today that ranks higher, either in importance to the national welfare or in the degree of challenge offered to the scientists and engineers, than that of guided missile development. The strong professional background of its scientists and engineers made it about inevitable that the Ramo-Wooldridge Corporation would take an active part in guided missile development programs. That's why responsibility for the Air Force Intercontinental Ballistic Missile and the Intermediate Range Ballistic Missile Programs—as far as overall systems engineering and technical direction are concerned—was given to the Ramo-Wooldridge Corporation.



An essential policy established by the Ramo-Wooldridge Corporation is that of maintaining a strong program of supporting research in fields related to the company's major technical areas of activity, but not otherwise directly associated with development projects.



While some supporting research can best be done within the operating divisions that are responsible for development projects, other research work is more appropriately done within separate organizational units. The Aeronautical Research Laboratory and the Electronic Research Laboratory are the divisions in Ramo-Wooldridge that are exclusively devoted to basic or supporting research.

Such research, through the development of new techniques, which are improved and refined goes a long way toward insuring the maintenance of advance scientific and engineering standards throughout the organization. ★

The Ramo-Wooldridge Big Five for Missiles from top to bottom: Dr. Louis G. Dunn, VP and Director of Guided Missile Research Division; Dr. Edward B. Doll, Program Director for the ATLAS, Guided Missile Research Division; William H. Duke, Program Director for the TITAN; Dr. Reuben F. Mettler, Program Director for the THOR; and Adolph K. Thiel, Assistant Program Director for the THOR.

WHO'S GOT WHAT?

The nation's mushrooming ICBM and IRBM missile programs, already approaching the $1 billion mark in allocated Defense spending, have spread in octupus fashion to virtually every segment of U.S. industry. At last count the two programs listed some 17 prime and more than 200 subcontractors.

From the "big five" basic weapons project—Convair's *Atlas* and Martin's *Titan* in the intercontinental category and the Douglas *Thor*, Army Ballistics Missile Agency's *Jupiter* and Lockheed *Polaris* in the intermediate range role—key development contracts for their propulsion, guidance, nose cone structure have dispersed the projects coast to coast.

Only a handful of the key participants have been named. Even fewer have been officially pinpointed to specific projects.

Here's how the big five projects shape up:

Convair's *Atlas*—Air Force has awarded an initial contract valued at $145 million for airframe development, excluding propulsion, guidance and nose cone work. Convair Astronautics Division, organized specifically to handle the *Atlas* and future projects of its type, expects to begin occupying its new $41 million plant at Kearny Mesa near San Diego in June. Eventually, employment in Astronautics Division will reach 6,600.

In *Atlas* propulsion, prime producer is North American's Rocketdyne Division, although Aerojet-General is prominently tabbed as supplier of a second-stage power unit. Rocketdyne, which will supply the *Atlas*' two estimated 100,000 lbs. thrust liquid rocket motors, last month occupied its new $4 million plant at Neosho, Mo. The new midwest location is part of an overall $13.2 million construction project there to gear the division for ballistic missile propulsion work.

Nose cone for the Convair ICBM is being developed by General Electric's Missile & Ordnance Systems Department formed during the past year at Philadelphia. As an index of the pressing task at hand, GE already has subcontracted fabrication of nose cone structural components to Republic Aviation Corp. in a $500,000-plus project.

For guidance, the *Atlas* project looks to General Motors AC Spark Plug Division and another GE department, Heavy Military Electronics, at Syracuse, N.Y. AC's guidance is inertial in variety, that of GE involves radio ground guidance techniques.

Martin's *Titan*—An initial USAF development contract totaling $358 million has reshaped the geographic organization of its prime airframe contractor—The Martin Co. The *Titan* program, centered by Martin in a new $10 million facility in Denver, is already outgrowing the bounds of initial planning.

As a result, a $2 million plant expansion is already in the mill. Present employment of 2,500 is expected to reach 5,000 next year.

Titan propulsion is assigned to Aerojet-General at Azusa, Calif. Prime contractor for nose cone development is Avco Manufacturing Corp. at Lawrence, Mass. with Lockheed Aircraft Corp.'s Missile Systems Division lending research support to both the *Atlas* and *Titan* nose cone R&D effort via its X-17 research project.

In *Titan* guidance, American Bosch Arma Corp. of Garden City, N.Y. is spearheading inertial guidance development and Bell Telephone Laboratories/Western Electric Co. at Whippany, N.J. is working on radio guidance.

Douglas *Thor*—The Air Force's IRBM entry, already in the test stage, is supported by an initial development and evaluation contract totaling $67.5 million. In addition to AF contracts of $1,305,500 and $2,340,083, Douglas is investing $3 million in facilities for *Thor* development and testing in the Sacramento, Calif. area. Contracts amounting to $2 million already have been let for construction on a 1,700 acre site there.

Propulsion for the *Thor* is being handled by NAA's Rocketdyne Division, guidance by AC and Bell Laboratories, all repeaters from the ICBM program.

In all three USAF ballistic missile projects, two other firms hold key contracts. The specialized task of developing warheads belongs to Sandia Corp., Western Electric subsidiary at Albuquerque, N.M. Engineering responsibility and technical direction for all AF ballistic missiles is vested in Ramo-Wooldridge Corp.

Jupiter—Army's IRBM under technical cognizance of Army Ballistic Missile Agency at its Redstone Arsenal has airframe development assigned to Chrysler. Total funds amount to an estimated $140 million. Prime production of propulsion has been awarded to North American for a 135,000 lb. thrust liquid rocket, although Aerojet-General is known to have developed what it calls the "largest solid rocket ever used" for the *Jupiter* IRBM.

Polaris—newest of the IRBMs, resulting from Navy split with the Army in intermediate range ballistic missile development, has airframe development at Lockheed Missile Systems Division. Also in this project are Aerojet-General Corp., presumably with the large solid rocket it developed for the *Jupiter*, General Electric and Massachusetts Institute of Technology, both of the latter in guidance development.

In addition to these prime development assignments, American Machine & Foundry Co.'s Turbo Division is developing auxiliary power units for unnamed missiles.

Two missile firms, Associated Products Corp. of Pomona, Calif. and Hallamore Electronics of Anaheim, Calif. have opened Denver facilities as subcontractors to Martin in the *Titan* program. Hallamore is also subcontractor to Convair in the *Atlas* project.

Baldwin-Lima-Hamilton Corp. holds subcontracts from Martin for *Titan* test stands and, in turn, has contracted with Beckman Instruments, Inc. to supply specialized computers. Douglas also has ordered Beckman data processing equipment to speed *Thor* research.

Burroughs Corp. holds contracts for data processing equipment in the ground control equipment for the IRBM/ICBM program. Fruehauf Trailer Co., Los Angeles plant, is building special *Thor* truck-trailers under a $1.5 million subcontract from Douglas.

But these are only a few of the 200 subcontractors active to date in the ICBM and IRBM in the programs. The roster of the unnamed, obviously even more impressive by its numbers alone, remains to unfold.

SPACE POWER

When US Air Force becomes US Space Force

by Dr. Donald Cox
The Martin Company

AT SOME historic moment between July, 1957, and December, 1958, a great, three-stage rocket will roar upward from the sands of Patrick Air Force Base in Florida. Shedding its expendable parts as it rises, the rocket finally will reach the fringe of outer space. Here, 200 miles away from earth, it will release a gold-plated sphere about the size of a basketball. This object named *Vanguard* will be the first of many artificial satellites.

The *Vanguard,* propelled by its own momentum, will follow an elliptical orbit at an initial speed of 18,000 mph. For a while, the speed will counterbalance the earth's gravitational pull, and the satellite will complete one revolution about once every 90 minutes. Eventually, as momentum slows the satellite the *Vanguard* will sink into the denser atmosphere nearer earth until it is consumed by friction.

Briefly, the disintegrating satellite may resemble a meteor to earthbound observers far below. But by then, instruments rested in the *Vanguard's* shell will have transmitted vital data to the scientists of more than forty nations, whom we are encouraging to track the satellite. In time, these men and women who represent participating countries in the 1958 International Geophysical Year, will translate the space messages into knowledge that may help mankind make use of infinity for commerce or for war.

Dr. Hagen, the Chief Scientist in charge of the *Vanguard* project, stated on a recent TV interview that he hoped the first satellite would: 1. help us find the true shape of the earth, 2. discover

Above the troposphere, which ends at 13,000 feet, man's stairway from up to out begins. Now the technologically more advanced nations are vying for top-dog position in the stratosphere. Within a decade unmanned vehicles will carry this race into interplanetary space.

The Legal Aspects

One of the interesting developments at the American Rocket Society Spring Meeting in Washington earlier this month was the Space Sociology Seminar in the afternoon session on Thursday, April 4, which was presided over by Dr. Theodore von Karman, Director of the Advisory Group for Aeronautical Research and Development of the North Atlantic Treaty Organization.

Andrew G. Haley, General Counsel of the American Rocket Society, read a paper on "Space Law and Metalaw—Jurisdiction Defined." In his talk Haley pointed out that he had been criticized by Mr. A. E. Slater in a recent issue of the Journal of the British Interplanetary Society for not adequately defining the *jurisdiction* of space law. Haley stated that after making a careful study of the writings of authorities on the subject, he determined to seek out a definition of space jurisdiction based upon principles derived from scientific considerations.

"At about this point in my quest," Haley said, "I received a telephone call from Dr. Theodore von Karman inviting me to spend the evening with him. He had just arrived in Washington from Paris.

"By coincidence, this summons started a chain of memories. One of these was in the autumn of 1942, when 'the Boss,' as I was privileged to call the good Doctor, advised me confidentially that the University of California at Los Angeles was to award him an honorary degree and would I be kind enough to attend the presentation. A short while later, at the general convocation, the Provost of the University of California at Los Angeles, awarded the Boss with the degree of Doctor of Laws! On the way back to Pasadena, we had a great deal of fun speculating on the future career of Attorney von Karman.

"So a few weeks ago as I pondered on space law jurisdiction, and my forthcoming visit with the Boss, my mind went back fifteen years to this incident and I decided, as of old, to discuss my problem with the good Doctor. As always, Dr. von Karman formulated a precise answer as to the jurisdiction of space law. During the evening he told me that he had delivered a paper last year at a luncheon at the University of California, Berkeley, entitled 'Aerodynamic Heating—the Temperature Barrier in Aeronautics' and in that paper he had occasion to use a diagram made by Masson and Gazley of the Rand Corporation showing the possible ranges for continuous flight in the velocity-altitude coordinate system. Later on, he sent me a copy of his paper which contains the Masson and Gazley diagram. He said that this diagram, although designed to show the variation of velocity versus altitude for various values of dynamic pressure and equilibrium pressure, could readily be used to show the regimes of atmospheric and extra atmospheric flight and to depict the jurisdictional boundary lines thereof.

"I have re-done the Masson and Gazley diagram to indicate a line showing orbital velocity and another line showing the boundary of the Keppler regime [escape velocity].

"Conditions for accomplishing aerial flight, that is, circle at constant altitude, is weight = aerodynamic lift plus centrifugal force. The aerodynamic weight decreases with altitude because of the decreasing density of the air and in order to maintain continued flight beyond a certain point, centrifugal force must take over. Consider the flight of Captain Ivan C. Kincheloe, in which he took the X2 rocket plane to 126,000 feet altitude. His flight was strictly an aeronautical adventure and did not partake of space flight. At M = 3 aerodynamic lift carries 98% of the weight and only 2% is centrifugal force, or 'Kepler force.' However, it will be noted that in the corridor of continuous flight when an object reaches *approximately 275,000 feet* and is *traveling at 35,000 feet per second,* the Kepler force takes over and aerodynamic lift is gone.

"I have reproduced the Masson and Gazley right side curve—so-called temperature carrier, or heat barrier, simply to show the present state of the art, and thus to delimit the corridor of continuous flight. This line has nothing to do with the jurisdictional question as improved techniques in cooling and discovery of heat resisting materials will undoubtedly change this curve.

Thus, the jurisdiction question is settled from a scientific angle."

the true nature of the earth's atmosphere, and 3. find out about the sun's ultra-violet and infra-red radiation. Outerspace travel may take a few years, but the time for contemplation has already arrived.

Men must be mentally and emotionally prepared for the revolutionary experiences now in prospect, including an understanding of some of the political, military, economic and social implications involved.

We have discovered a new frontier with problems similar to those of western America in the latter 19th Century. Like the settlers in the old West who lost their claims if they did not protect them, so we have the challenge of exerting our claims over space, and keeping it out of the hands of enemy "rustlers."

"Space" and "Spacepower"

The atmospheric frontier or interplanetary space begins between 400 and 2000 miles up. This is known technically as the exosphere.

Space vehicles, when they are perfected will be beyond the earth's gravitational pull and beyond the sound barrier, about 450,000 feet up.

When man breaks through the envelope surrounding the earth, he will, from a military standpoint not only have to be on the lookout for possible "Martians" in space but more immediately will have to assure himself that his nation's air space is controlled and adequately protected.

Spacepower is dependent on airpower control in the atmosphere below the space frontier. They should never be thought of separately.

Due to the limited altitudes of present-day air vehicles, powerful military nations in peacetime can control their air space as a privileged sanctuary under the rules of international law. The advent of space satellites, guided missiles, and space ships whether atomic, chemical, or rocket powered will lead to a revolution in national air sovereignty.

From the launching of the first earth satellite, a new era will have begun, i.e., the ending of national control over air space. For space is truly international, no matter how one cuts it. Any point at 200, 300, or 1000 miles up probably dominates parts or all of two or more nations on the face of the earth simultaneously, and this makes for complications in the problems of international relations regarding former aerial domains.

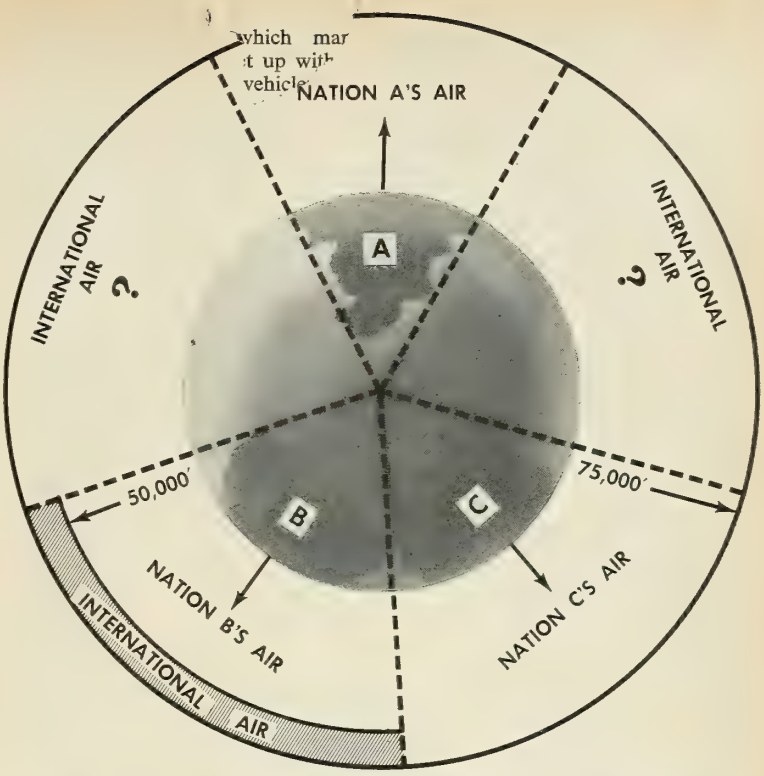
The elimination of national air and space boundaries would mean a 'fait accompli' victory for President

Eisenhower's open sky policy, whether other nations accept this fact by signatures on diplomatic documents giving permission, or not. For once the first satellite is launched, it will only be a matter of time before powerful aerial cameras are perfected to transmit pictures of enemy territory and installations back to earth. Constant inspection of every country, city, and body of water can be maintained by such satellites, and could set our warning bells ringing against any future Pearl Harbor buildup.

In a June 1956 issue of *Life* magazine, Charles J. V. Murphy wrote ". . . an effective space platform, equipped with cameras and telemetering devices, would provide either the Russians or ourselves with a means of continuous surveillance of each other's industrial and missile deployments—crucial intelligence in a period when nations will have power to obliterate their enemies."

The higher the altitude, the more earth's surface will be dominated by any one space vehicle—former safety zones on earth will be all but eliminated. Still to be determined is the altitude at which a nation's air sovereignty ends and "open" space begins.

Another thing that will end national boundaries, is the necessity for dispersed, international ground control nets to guarantee that space vehicles reach the proper altitudes for operation. While flying over foreign territory, a space vehicle must often rely on ground control stations in that country to gain the proper altitude.



Thus, a few of the larger territorial nations could hamper other nations' attempts to perform high altitude flying if they try to retain their "sovereign air space."

The s e c o n d obvious c h a n g e brought by the conquest of space is: The limitations of any single nation's spacepower will depend on the speed, altitude, and staying ability of their space vehicles.

These three factors will become a primary deterrent of future conflict, as long as peace-loving nations can keep their vehicles out the farthest and up the longest without refueling.

These three factors alone, however, will not guarantee that nation A will always be able to exert its will of space control over nation B and C.

The interrelation of each of these factors is significant because you cannot have one without the other. To obtain the highest altitudes, great speed is necessary and inability to attain the higher altitudes prevents great speed. The addition of "staying ability" guarantees that the duration, speed, and

International law now reads that a nation holds sovereignty over all above and below the surface of the earth under its control, plus a pre-stated distance out over the water. This is a simple concept that has worked reasonably well for thousands of years. However, it cannot be extended indefinitely outward to the infinite reaches of galactic space. It probably won't even work 500 miles up. The top illustration shows how vertical aerial boundaries become radial when vast altitudes are considered. Both diagrams emphasize the importance of maintaining technological superiority in order to get manned vehicles to the highest altitude.

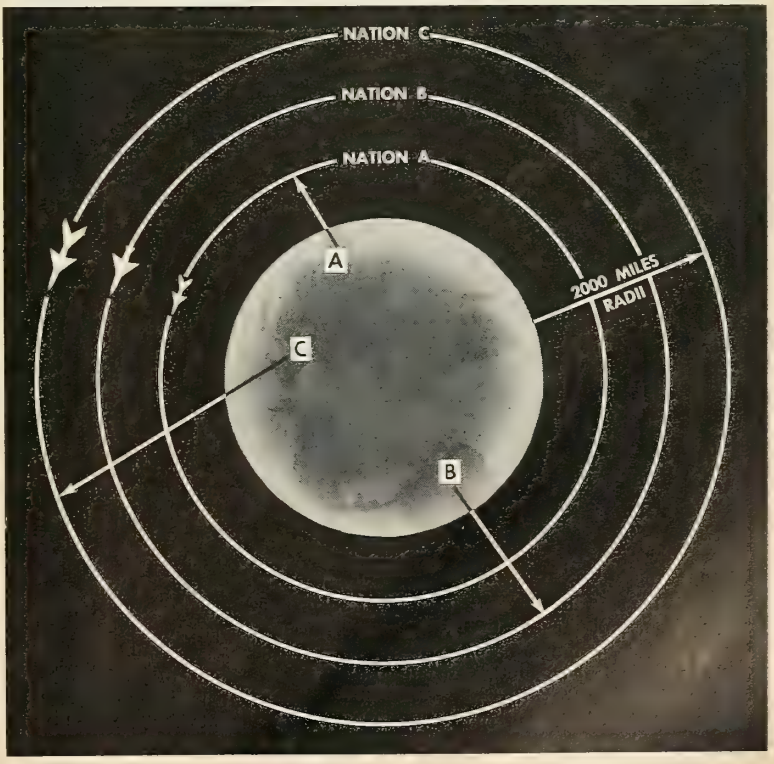


Diagram shows how a satellite will be able to dominate more than one nation at a time. The higher the orbit of the satellite, the greater earth area will come under its surveillance. Additionally, either manned or unmanned space satellites at the higher altitude would be in an advantageous position to take action against those below. In the one case missile assault would be aided by gravity; in the other, it would be hindered.

height of any vehicle will remain constant—otherwise, it will fall back to earth and lose speed as it re-enters the denser atmosphere.

Control of Space

Current U.S. Air Force doctrine is based on control of the air. Since the degree of control by our (and our allied) air forces is relative at any given moment, several factors become apparent when we extend this theory to "control of space."

The higher man ascends through the fringes of the atmosphere and into the frontiers of outer space, the more difficult it will be for him to control absolutely the significant portions of the air ocean and space between him and earth. This assumption, when extended to its logical conclusion, would lead one to believe that to retain comparative control of air and space, nations would have to numerically or qualitatively increase their air and space vehicles in direct proportion to the additional miles of altitude. They would have to provide for complete serveillance and countermeasures.

The characteristic of vertical employment is one of the advantages of airpower and space power over land and water-borne war weapons. The extended application of this characteristic to higher altitudes multiplies the problem of control over the dominions of outer space and the earth's atmosphere. The nation that masters speed and altitude coupled with staying power will be in a better position to dominate the world even though the problems and areas of control are more difficult in scope.

Such a nation could also better guarantee freedom of flight although fixing set frontiers in the layers and spheres of the atmosphere and space would be difficult to determine.

The Higher Out, the Easier Control

To offset the disadvantage of higher altitude—more space to control in all directions—is the advantage of being on top. It's like standing on the summit of Mt. Everest, with all the rest of the known earth's crust below.

So it is true of altitude in space. Knowledge that other nations have not ascended as high as you, gives the top nation a feeling of security that no others can have, a command control of the earth. On this point Professors Stefan Possony and Leslie Rosensweig in a significant article entitled "The Geography of the Air," published in May 1955 in the *Annals of the American Academy of Political and Social Science* wrote:

". . . As man reaches upward to the outer atmosphere new political problems arise, the nature of which we are not yet able to grasp. Heretofore, the relations between nations took place on what in practice was a plane. During the time of low altitude flying, the relations between nations and military forces were determined by the geometry of a spheroid's curved surface. This period of close-to-the-ground flying was, and still is characterized by 'the polar concept.'

"Henceforth, international relations will be geared to the more difficult geometry of a large spheroid enveloping as its core a smaller and impenetrable spheroid; the earth. But even more confusing, the radius of the outer spheroid—symbolizing the aeropause or the altitude which man has attained at any given time—is expanding.

"The most advanced nation technologically will operate within the highest aeropause, while the spheroid circumscribing the aerial capabilities of the more backward nations will have shorter radii.

Hence in the future, the geography of power will be described by several enveloping spheroids of different sizes. It will be a far cry from the geography of the battles of Yorktown and Bastogne, or even from the aerial battles of World War II. Truly a new *Weltbild* is emerging."

Technically, as Dr. Wernher Von Braun pointed out you can bomb a certain spot more accurately from 2,000 miles out in space than 5 miles up in the air from the target—since you would have control of the bomb all the way to the target in the former situation, but not in the latter.

Sustained Flight Vital

Those nations which can successfully launch and maintain the greatest number of manned and unmanned satellites in space, will have more op-

portunities to exert their will in the air and space medium.

This fact makes the perfection of long-range, nuclear-powered air vehicles a significant step forward in maintaining air and space superiority. The prolongation of flight around the earth by manned nuclear air vehicles will help make possible a continuing space sentinel system, not possible before.

The perfection of nuclear powered air and space vehicles will make control more feasible as a nation's nuclear power capabality increases. Such sustaining ability at the highest altitude and with the greatest speed will enable the leading nation to achieve five fundamental military aims: (1) persuasion, (2) neutralization, (3) denial, (4) destruction, and (5) capture. Applied spacepower would make the first three particularly effective. The last two—destruction and capture—need never be carried out if the first three are applied judiciously by the space power nation exerting them.

Space Counter Measures

Nuclear powered space vehicles would have to be knocked out somewhere in space rather than at their launch sites, unlike the current theory of stopping aggression on the ground before launching. As this type of vehicle is not a land-oriented vehicle, there is only one place it can be destroyed, and that is in its natural habitat—air space. To concentrate on finding an enemy's space launching sites on land would be well nigh impossible after hostilities had started unless one was thinking of a preventative war. Even then, the main threat which would already be air and space borne, could not be overlooked.

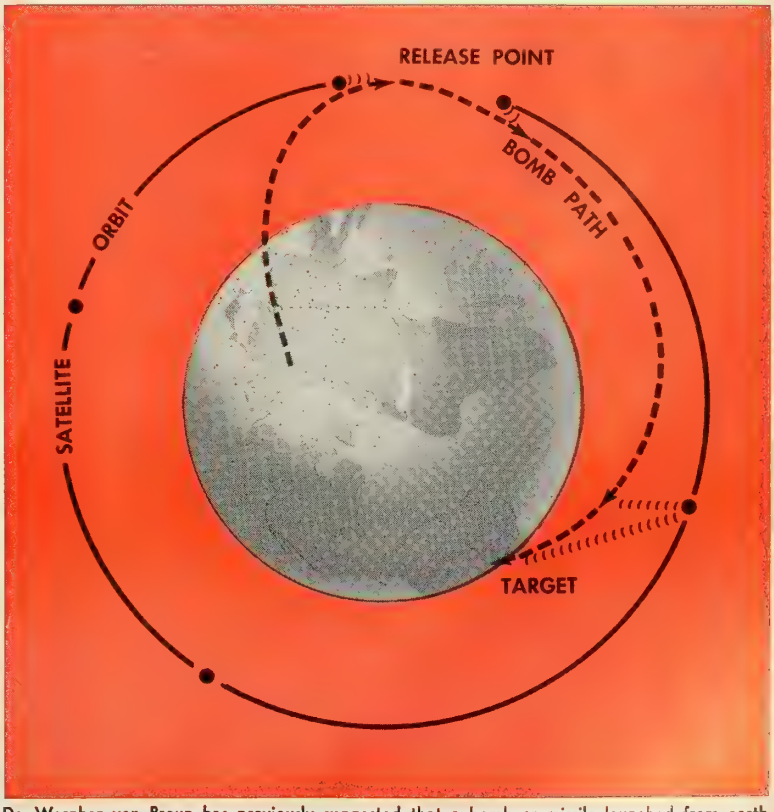
As more potentially destructive vehicles will be in flight rather than at their launching sites at the outbreak of hostilities, an added burden is placed on the defender nation. In some respects it would be an almost impossible task for a nation to defend itself against a multitude of enemy "flying saucers" constantly whirling around the earth in their space orbits.

With the *Vanguard* test firing program already under way, perfection of the ICBM in sight and with serious plans to go ahead with hypersonic boost glide vehicles, the problems of space flight and control are not somewhere in the eventual future. They will first arise during the next decade, develop to full proportions during the life of the current generation.

These combat space vehicles pose a defense problem which defies the limits of man's imagination. This also holds for the planetary objects, cosmic particles and meteors which man-made air vehicles will meet up with in space. Either the space vehicles will have to ward off such objects or suffer the consequences.

In one sense, as we stand on the threshold of space, we find ourselves in a similar state as the hunter on a safari at the edge of a dense jungle. The size and number of his weapons, will determine how far into the jungle he can penetrate with hopes of returning safely. He knows that he can't go too far in if he doesn't have the implements to fight his way out alive. Such is the military problem facing the Western World as it ventures into the space frontier.

The Ultimate Challenge



The public relations department of the Glenn L. Martin Co., prime contractor for the first satellite launching vehicle *Vanguard* in speaking of its forthcoming endeavor, remarked:

"Thus one day soon, in the hour before sunrise, as men the world over train their binoculars upon a brilliant point of light in the sky, they may well reflect upon the universality of man's faith in the infinite future of man."

This "reflection" is needed now to help coin a valid space doctrine to keep the myriad space satellites, rocket ships, intercontinental missiles and space stations from getting out of control. Such a doctrine is necessary to provide a secure foundation for "spacepower" in the future, and to aid us in understanding the technologically complex struggle for control of the earth's air and space beyond.

As the air and space revolution gathers momentum, we are challenged as never before to face up to the tasks of our new international spacepower and learn to cope with its unchanging nature. The hopes and fears of our civilization are tied to the necessity of such an understanding now.

Space flight will help to modify the world—rather than divide it. True space flight to the planets and the stars will only come after the world is united and the threat of war removed. This is the ultimate challenge to mankind, so that spacepower can be used for predominately peaceful purposes. ★

Dr. Wernher von Braun has previously suggested that a bomb or missile launched from earth could be picked up by a manned satellite, carried half way around the earth, released and guided down to its target—another concept of importance when considering space-power.

CONTACTS FOR CONTRACTS

If you want a contract with the Air Force Office of Scientific Research, first familiarize yourself with the basic thinking of the men who run it.

AFOSR is one of 12 centers of the Air Research and Development Command, with headquarters in Washington, at 14th Street and Constitution Avenue Northwest. It has been given the mission of conducting the *exploratory* research program for the U.S. Air Force. The word "exploratory" is the key to its aims and objectives.

Admittedly, exploratory research, as defined by AFOSR, has a relatively low success probability, but a very high pay-off if successful.

The table of organization of AFOSR shows how well organized is this branch of the Air Force. It includes nine divisions representing basic scientific disciplines; behavioral sciences, mechanics; aero-medicine, combustion dynamics, physics, chemistry, solid state sciences, mathematics and nuclear physics.

These divisions are grouped under four "directorates." These are the Directorate of Bio-Sciences, the Directorate of Aeronautical Sciences, the Directorate of Physical Sciences and the Directorate of Material Sciences.

There are also the Directorates of Advanced Studies, of Research Information and of Procurement.

In establishing contact with AFOSR, a prospective research contractor should address his original letter of inquiry to the Commander, Brig. Gen. Hollingworth F. Gregory. A contractor's contacts with the organization will generally be with the division covering the scientific discipline, which handles the technical aspects of contracts, and the Directorate of Procurement, which deals with the financial aspects of negotiating, renewing the contract.

A primary proposal should state the field of investigation, the specific objectives, previous work done, the method of investigation and the estimated total cost. It should also list the names of the principal investigators and what percentage of their time would be devoted to the project.

The preliminary proposal is evaluated by the appropriate technical division and its consultants. If it is favorably received, the investigator should be prepared to submit a more elaborate and detailed proposal, for which instructions will be furnished.

The Armed Services Technical Information Agency in Dayton, Ohio, provides a service for the exchange of scientific and technical information to prime contractors of the military departments and, under certain circumstances, their subcontractors.

But for those contractors, or prospective contractors, who want a detailed statement of the research interests of AFOSR in the fields it covers, a 16-page booklet on the subject can be obtained by writing to AFOSR.

1. **Directorate of Aeronautical Sciences.** The Mechanics Division of DAS is interested in aerodynamics, aerostructures, and both aerodynamic and structural problems at high speeds. Aim of its aerodynamics program is to assure the continued growth of this science and to evaluate new knowledge.

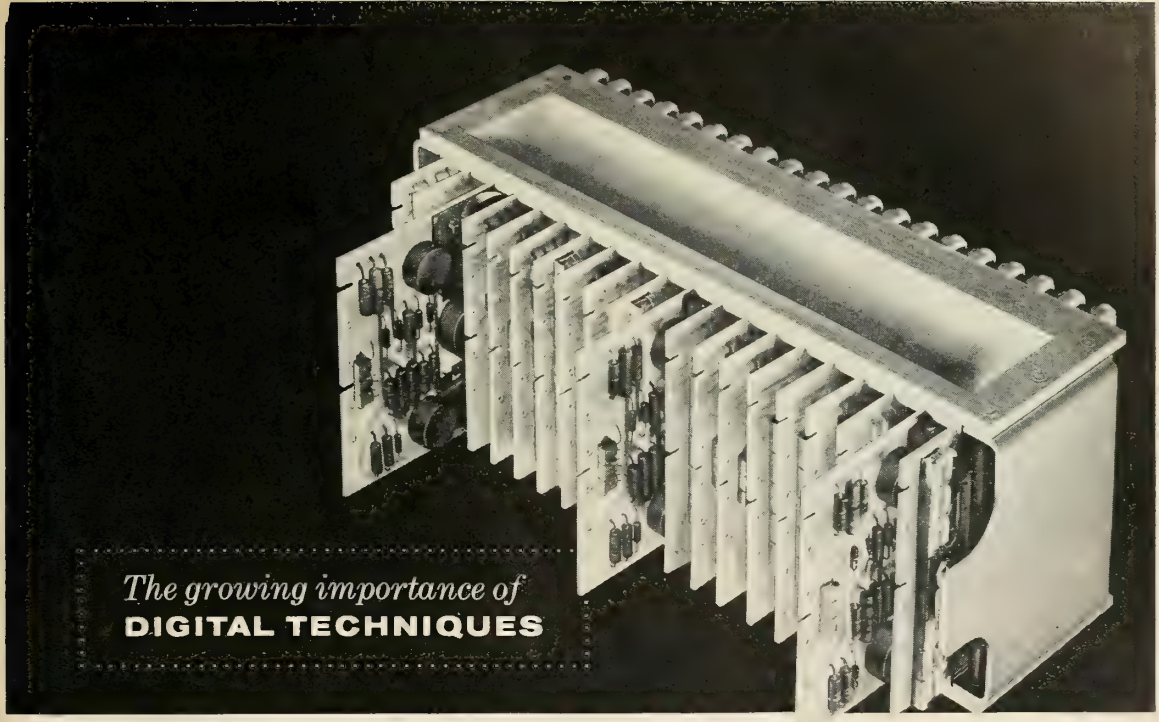
Principle subfields of interest are: subsonic flow (Mach 0.8), hypersonic flow (Mach 0.8-1.1), supersonic flow (Mach 1-5), hypersonic flow (Mach 5), internal flows, aerothermodynamics, rarefied gas dynamics, turbulence and facilities, instrumentation and techniques for model and full-scale testing.

Fluid mechanics is another subject of considerable interest to the Mechanics Division. At hypersonic speeds, not only is a vehicle—whether an ICBM or an earth satellite—heated to extreme temperatures, but even the air around it undergoes changes in state and composition. These changes, it is pointed out, have marked effects on aerodynamic and structural design considerations. Research interests in this area encompass the determination of the fluid dynamics and the chemicophysical laws governing vibration, dissociation, recombination and ionization of gases and their effects on the aircraft structure.

The Combustion Dynamics Division of the DAS is primarily concerned with the physical and chemical processes by which energy is provided for the propulsion of aircraft. This includes the problem of energy storage, which requires thorough basic knowledge of the various forms of potential energy: nuclear, atomic and molecular binding energies, as well as gravitational and electromagnetic potential energy.

2. **Directorate of Bio-Sciences.** The Aeromedical Division of this directorate is interested in biological and physiological operational and environmental stresses. The object is to provide protection against various adverse conditions and to improve performance under those conditions.

The Behavioral Sciences Division of this directorate initiates both basic and exploratory research that will contribute to the better understanding of human behavior. This division encourages "interdisciplinary" research in the psychological, anthropological, sociological and psychiatric disciplines, utilizing existing research personnel and facilities.



3. **The Directorate of Physical Sciences.** The Physics Division is concerned with the study of atoms and molecules as the basis for interpreting many of the properties of matter. It is also interested in the properties of electro-magnetic radiation which are used for communication or detection.

In the field of atomic and molecular physics, infrared and ultraviolet radiation, thermodynamics and statistical mechanics, molecular structure, acoustics and hypervelocity particles are all of particular importance to AFOSR.

The Nuclear Physics Division of this directorate is concerned not only with the development of nuclear power and its related problems but also provides information to improve the properties of materials. For example, new applications appear possible in the use of nuclear resonance which would aid in the chemical-trace analysis of certain types of impurities. The division also is interested in nuclear structure and reactions, cosmic rays, fundamental particles and nuclear instrumentation.

4. **The Directorate of Material Sciences.** The Chemistry Division of this directorate is interested in many subjects, including: the theory of chemical bonding, chemical reactivity, new compounds, high-temperature materials, catalysis, surface chemistry, photo chemistry, nonequilibrium kinetics, nuclear chemistry and high-temperature reactions.

The Solid State Sciences Division of this directorate has established its ultimate aims as follows: (1) to make better use of desirable physical properties of solids for Air Force use and (2) to discover new phenomena that might lead to novel applications.

As recently as ten years ago it was just becoming evident that digital techniques in electronics were destined to create a new and rapidly growing field. Today, incorporated in electronic computers and other equipment, they constitute one of the most significant developments in scientific computation, in electronic data processing for business and industry, and in electronic control systems for the military. In the near future they are expected to become a major new factor in industrial process control systems.

The digital computer for scientific computation is becoming commonplace in research and development laboratories. Such machines range from small specialized units costing a few thousand dollars, to large general purpose computers costing over a million dollars. One of these large computers is a part of the Ramo-Wooldridge Computing Center, and a second such unit will be installed the latter part of this year. The digital computer has not only lightened the computation load for scientists and engineers, but has made possible many calculations which previously were impracticable. Such computers have played a major role in the modern systems engineering approach to complex problems.

Electronic data processing for business and industry is now well under way, based on earlier developments in electronic computers. Data processors have much in common with computers, including the utilization of digital techniques. In this field, teams of Ramo-Wooldridge specialists are providing consulting services to a variety of clients on the application of data processing equipment to their problems.

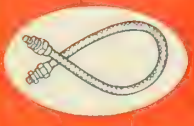
The use of digital techniques in military control systems is an accomplished fact. Modern interceptor aircraft, for example, use digital fire control systems. A number of Ramo-Wooldridge scientists and engineers have pioneered in this field, and the photograph above shows a part of an R-W-developed airborne digital computer.

These, then, are some of the aspects of the rapid growth which is taking place in the field of digital techniques. Scientists and engineers with experience in this field are invited to explore openings at The Ramo-Wooldridge Corporation in:

Automation and Data Processing
Digital Computers and Control Systems
Airborne Electronic and Control Systems
Guided Missile Research and Development
Electronic Instrumentation and Test Equipment
Communication Systems

The Ramo-Wooldridge Corporation

5730 ARBOR VITAE STREET • LOS ANGELES 45, CALIFORNIA



with the acquisition of FLEX-O-TUBE...

FLEXONICS CORPORATION

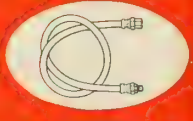
now offers the FIRST COMPLETE LINE of flexible connectors in all materials

FLEXON®
Metal Hose, Ducting and Connectors

METAL HOSE
Flexon metal hose in corrosion resistant alloys is manufactured in the broadest range of sizes and types for all aircraft applications.

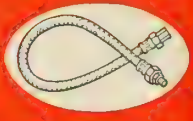
DUCTING
Flexon ducting, standard or high strength corrosion resistant steel is available in all sizes and shapes with or without insulation.

FLEXIBLE CONNECTORS
Flexon connectors in corrosion resistant alloys are made in a complete range of sizes and types including pinned elbow and gimbal joints.



BELLOWS
Flexon bellows are made in an almost unlimited range of sizes and types to meet the most advanced aircraft requirements.

FLEX-O-TUBE®
Rubber and Synthetic Hose and Fittings



BULK HOSE
Flex-O-Tube bulk hose is offered in a wide range of types and sizes for handling liquids and gases for automotive, aircraft and industrial services.

HOSE ASSEMBLIES
Complete hose assemblies are furnished with a broad choice of standard and special fittings for low, medium and high pressures.

TEFLON HOSE
Teflon hose and hose assemblies are offered for use where chemical and temperature resistance and light weight are required.

FITTINGS
Reusable, pressed on, clamp type, flange type, S.A.E. and special fittings and couplings are manufactured for all services.

Now at your service are the combined know-how and engineering and manufacturing facilities of two leading manufacturers of flexible tubing and aircraft assemblies and components. For you, it means better service on all your air, gas and liquid conveying problems.

In joining forces with Flex-O-Tube, Flexonics Corporation now offers combined experience totalling 85 years. The combined field sales and service organizations operate through offices in principal aircraft and engine manufacturing centers in the United States and Canada.

Now more than ever before it will pay you to bring your fluid conveying problems to Flexonics Corporation—the one manufacturer who can answer virtually every need.

PLANTS AT
Maywood, Illinois • Inkster, Michigan • Elgin, Illinois • Memphis, Tennessee • Rock Falls, Illinois • Savanna, Illinois • Elizabeth, New Jersey • North Hollywood, California • Brampton, Ontario • Windsor, Ontario

A-35

Flexonics *Corporation*

The Rocketdyne Boom:

Engines for USAF's Long-Range Missiles

WHILE SECURITY restrictions prevent a presentation of rocket engine facts in terms of thrust, specific propellant combinations and production figures, it is generally conceded that the rocket engine industry has made tremendous strides in recent years, permitting U.S. long range missile development to progress at an unprecedented and confident pace.

Some hints of this progress have been disclosed:

The range of the German V-2 propulsion system could be increased by from 50 to 100 per cent if we were to build a missile today of the same size, weight and payload.

The ultimate performance of propelled rocket engines liquid is governed only by the rate at which propellants can be pumped into the combustion chamber and burned efficiently.

In the field of fuels, research scientists see a 50 per cent increase in power potential before they reach an energy barrier. Beside the standard V-2 alcohol and liquid oxygen propellant, two other potent combinations of fuel and oxidizer have been brought into standard use today: nitric acid and aniline; and gasoline and oxygen.

Other promising indications: development of 12-inch-diameter gas generators that produce in the order of 10,000 isentropic horsepower in hot gases to drive turbopumps and successfull operation of the 50,000-lb. liquid propellant rocket engines in 120 test sled runs, indicating that new reliability standards are being achieved in the use of liquid fuel rocket engines.

These and other advances may be interpreted as significant indications that long range missile propulsion, through the use of high-thrust liquid propellant rocket engines, has caused a major technological break-through in this decade.

Starting with the Geman V-2 scientists and hardware following World War II, U.S. long range rocket propulsion technology progressed from the Air Force-North American *Navaho* propulsion system through the Army-Chrysler *Redstone* and into the realm of the Air Force's Ballistic Missiles Program in the intermediate and intercontinental range brackets (*Atlas, Titan, Thor*). Recent reports have placed the Army-Chrysler *Jupiter* alongside the *Thor* in the 1500-mile class.

Today's long range missile propulsion systems are the direct result of early confidence in the future of rocketry expressed by U.S. industry,

Long range propulsion systems require new—and expensive—facilities and techniques. Here, at Rocketdyne's Propulsion Field Laboratory in California, afterburners ignite gasses used in test of rocket engine gas generator. Note desolate, unpopulated area.

Rocket test rises stand from Missouri countryside as Rocketdyne pushes construction at its 200-acre test complex at Neosha. A major part of the ICBM program, this plant will test and construct high thrust liquid propellant engines.

and 12 years of engineering achievement in a field new to technology.

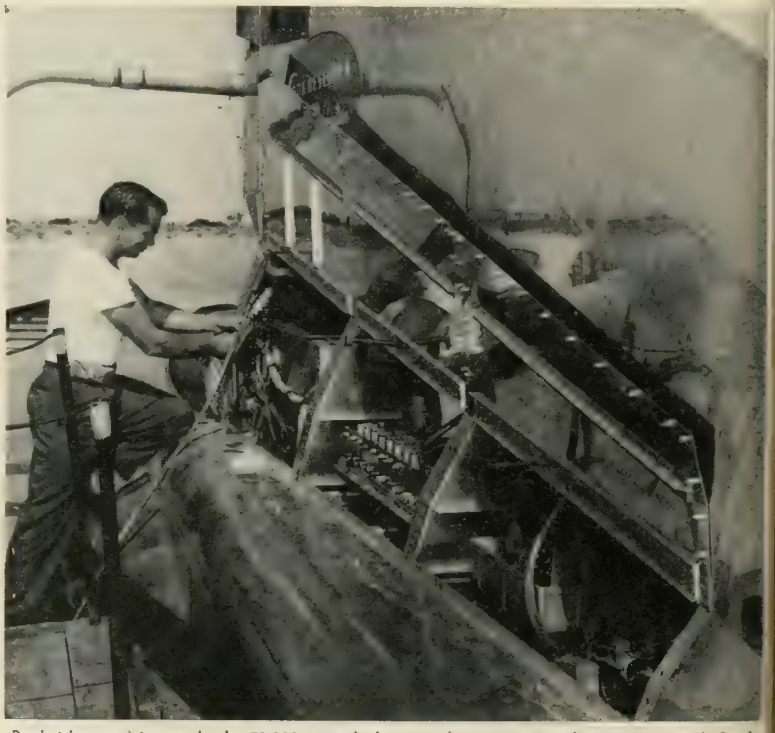
A leader in this field is Rocketdyne, a division of North American Aviation, Inc., now supplying high thrust rocket engines for virtually all of the long range missile programs.

The Canoga Park, California firm today employs more than 10,000 persons almost exclusively in the development and production of long range liquid propellant rocket engines for the Air Force's *Atlas* and *Thor* programs, the Army's *Redstone*, and *Navaho*.

Company officials were optimistic over the future of high thrust rocket propulsion following World War II, when NAA was asked by the Air Force to undertake development of the *Navaho* long-range guided missile.

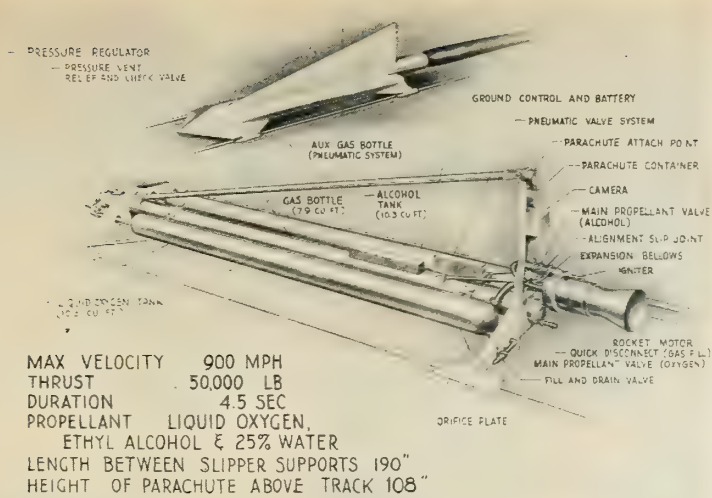
Starting with a nucleus of five research engineers in 1946, NAA President J. L. Atwood and others began the task of recruiting a scientific staff for the job, expecting that missile development would be the logical extension of the airframe business.

When progress had been made in their studies of high-speed aerodynamics, heat transfer and related subjects, the Air Force accepted an NAA proposal for institution of a long-range research and development program.



The late 1940's saw the establishment of a Propulsion Field Laboratory in the Santa Susana Mountains near Los Angeles, on 600 acres of isolated mountainside. Thus was born U. W. technology in the field of large, liquid propellant rocket propulsion.

After only eleven years in rocket propulsion Rocketdyne has brought the issue out of the doubtful stage and into the hands of assembly line production experts, who today are turning out rocket engines in much the same manner as fine quality automobile engines. Highlighting the division's manufacturing effort will be the full scale operation, this August, of the nation's first plant devoted exclusively to the production of long range rocket propulsion systems in Neosho, Mo. The $13 million Air Force-owned plant, including a 200-acre acceptance testing complex, is expected to employ 1,000 persons by late this year.



While early confidence in the future of long range rocket propulsion is largely responsible for Rocketdyne's success, company officials cited these factors as helping to close the area of doubt over the past 12 years:

A top level team of engineer-managers has been brought into the picture. Led by General Manager Samuel K. Hoffman, 55, with 32 years experience in aeronautical engineering including a professorship at Pennsylvania State; and Assistant General Manager Charles W. Guy, 40, who has been active in aircraft engineering and administrative posts since his graduation from MIT in 1939. He largely shoulders administrative jobs to free Hoffman for engineering decisions.

Other key men in the Rocketdyne management picture: Chief Engineer Thomas F. Dixon, 41, 10 years in long range propulsion engineering with NAA; Propulsion Field Laboratory Manager James A. Broadston, 48, 21 years with NAA and probably the Na-

Rocketdyne engineer checks 50,000 pound thrust rocket engine used in 5000 pound Cook parachute sled. Capable of reaching 900 mph in 4.2 seconds, this unit has successfully completed 120 test runs and boasts a largely trouble-free record of performance.

This schematic drawing shows operative details of the Cook sled propulsion system. In one tenth of a second from firing sled is accelerating at 10 G's, its engine having reached 80% of full thrust. Water wall that stops it gives 65,000 pounds resistance.

tion's top specialist on large rocket engine test; Preliminary Design Chief George P. Sutton, 37, author of "Rocket Propulsion Elements," vice president of the American Rocket Society; Neosho Plant Manager Joseph P. McNamara, 46, who was assistant to the division manager at NAA's Kansas City plant during World War II and has 22 years of diversified engineering experience; Research Chief John Tormey, 38, with 11 years' research experience with NAA, who directs efforts of 140 Rocketdyne researchers and is a top authority of high energy rocket propellants; Factory Manager Ross Clark, 45, who progressed from the position of assembly mechanic with Northrop Aircraft through 24 years of manufacturing experience to lead Rocketdyne's production effort.

Production experience gained during World War II on the F-51, B-25 and other airplanes has enabled Rocketdyne managers to recruit, train and utilize technical talent on a large scale. This explains why the organization has been able to expand from 4500 to 10,000 people within one year with a minimum of confusion. High-geared indoctrination programs, classroom training, quick dissemination of fresh information all figure in this program.

More than 4,100 persons are engaged in some phase of Rocketdyne's engineering effort today. Emphasis has been placed on attracting and training combination engineers. Test engineers, for instance, help design test stands, then assume responsibility for their operation. This requires civil, mechanical and electrical engineering know-how.

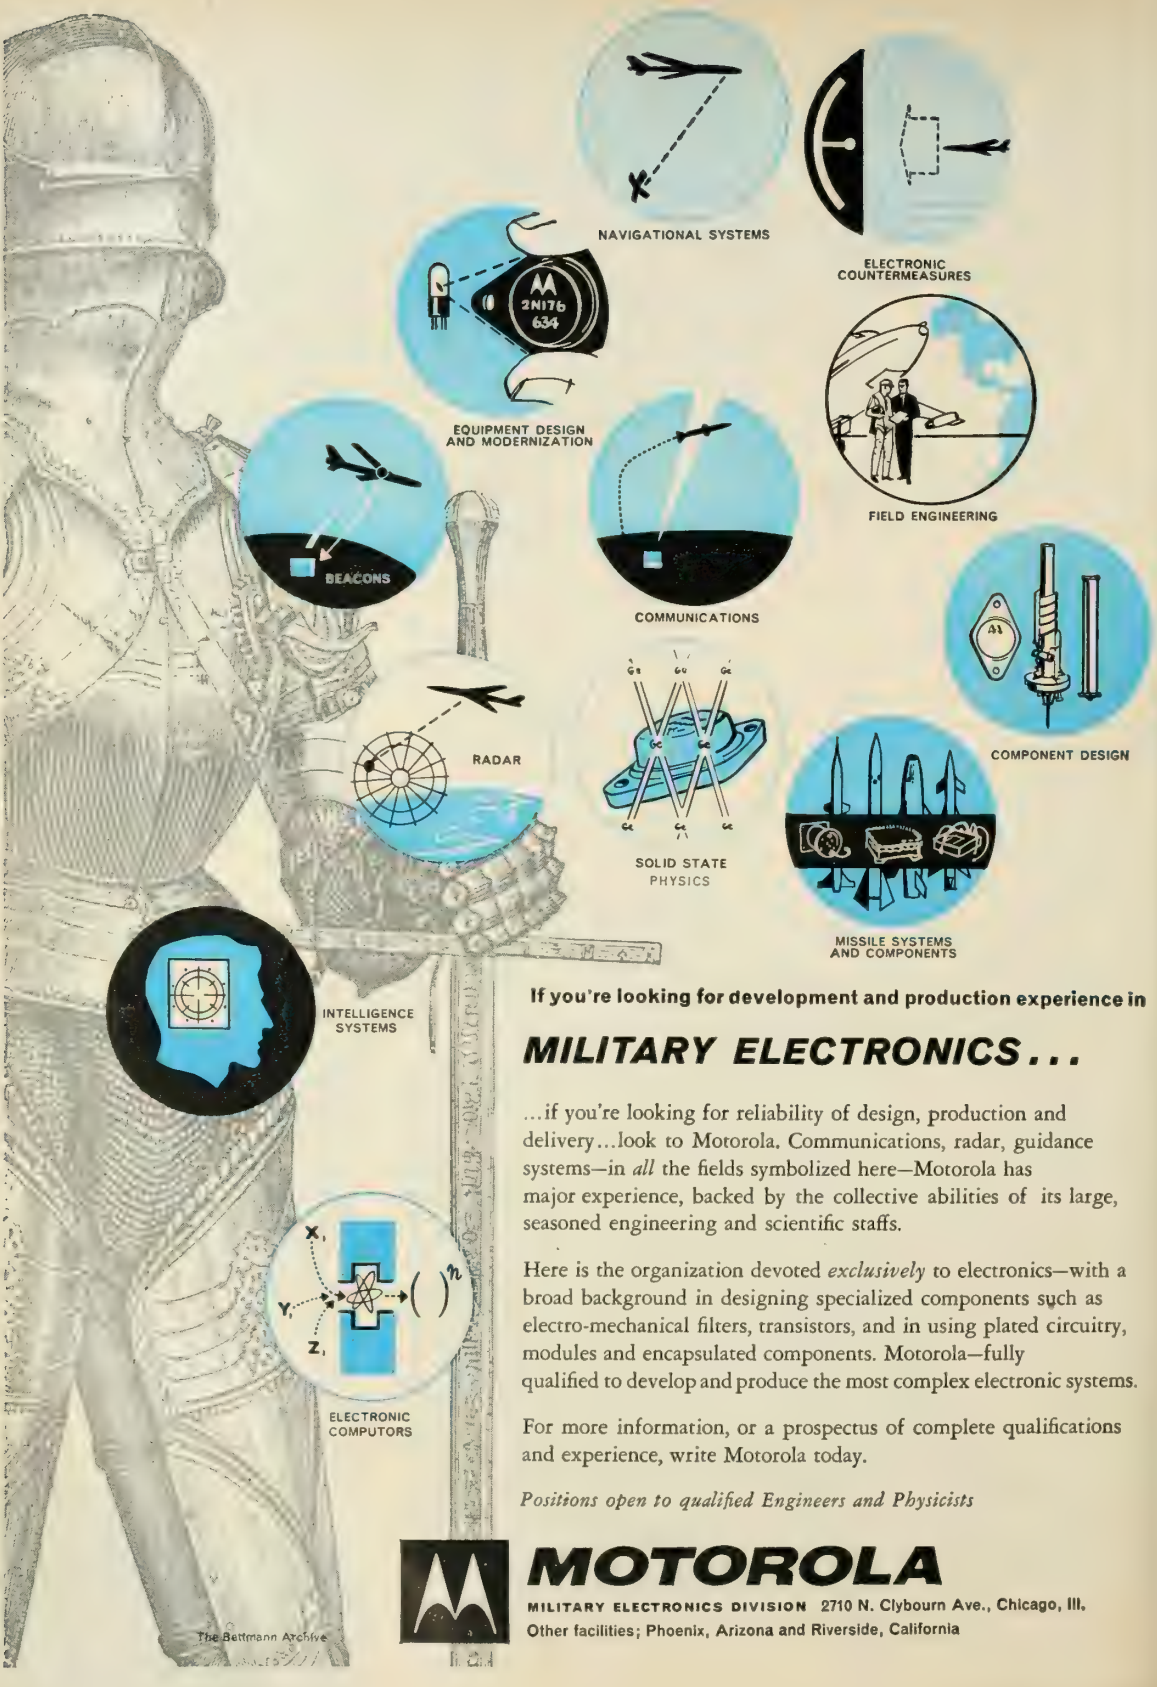
Development of hardware is based on solid, factual experience. Extensions of technology are founded on lessons already learned rather than unproven hypotheses. The result is a steady progression toward objectives.

From the standpoint of basic engineering design, there has been no sharp distinction from one stage to the next, with the exception of several components, whose redesign was necessary. Generally speaking, the components, controls, inter-connects and operating sequences were improved on the basis of test experience. The development of thrust chambers, turbopumps, propellant feed systems, feed system controls, gas generators and gas generator controls followed a logical sequence of improvement.

When necessary to meet tight military schedules, Rocketdyne has set up double shifts in production and testing activities. Maj. Gen. B. A. Schriever, commander of Western Development Division, ARDC, has cited Rocketdyne's double shift testing program in keeping production and delivery of engines on schedule.

Since completion of Rocketdyne's 316,000 square-foot Main Plant building in Canoga Park, California, in November, 1955, expansion has been rapid. In addition to the Neosho plant, operations have required addition of a 50,000 square-foot engineering annex and an 88,000 square-foot material building and six other supporting facilities within the last year.

While development of the art at Rocketdyne has been sober and well planned, engineers have not hesitated to follow strange pathways in their quest for fresh knowledge. As a result, their explorations in fluid mechanics, supersonic aerodynamics, thermodynamics, electronics and other fields, performance and reliability standards thought impossible 10 years ago have been achieved.



A good example is the problem of turbopumps. Pound for pound, the rocket engine turbopump is probably the most powerful pumping device ever developed by engineering skill. Because of the rigid requirements of turbopumps, Rocketdyne engineers have undertaken the analysis, design, development and testing of high pressure ratio supersonic turbines, high-speed gear boxes, radial and axial flow pumps, rotating and liquid gas seals and other mechanical components. The development of each presents a challenge.

In the field of instrumentation, the challenges have been similar. Typical of electronic advances at Rocketdyne is the IDIOT (Instrumentation Digital On-line Transcriber), which converts rocket engine test inputs at the rate of 10,000 per second, recording the numbers in binary code and magnetic tape. By playing back the tape through a digital computer, it is possible to process 4,800,000 separate readings in less than 15 minutes. Thus long range propulsion test data is almost immediately available for analysis, and performance improvement time is greatly reduced.

Such developments are significant in view of the fact that the tempo of our long range missile development—for the Nation's defense and for exploratory space travel—is governed only by the rate of our technological advancement.★

This pump shaft leads to underground receiving tanks at Rocketdyne's Neosha, Mo., plant. The company began moving in last month.

If you're looking for development and production experience in

MILITARY ELECTRONICS . . .

. . . if you're looking for reliability of design, production and delivery . . . look to Motorola. Communications, radar, guidance systems—in *all* the fields symbolized here—Motorola has major experience, backed by the collective abilities of its large, seasoned engineering and scientific staffs.

Here is the organization devoted *exclusively* to electronics—with a broad background in designing specialized components such as electro-mechanical filters, transistors, and in using plated circuitry, modules and encapsulated components. Motorola—fully qualified to develop and produce the most complex electronic systems.

For more information, or a prospectus of complete qualifications and experience, write Motorola today.

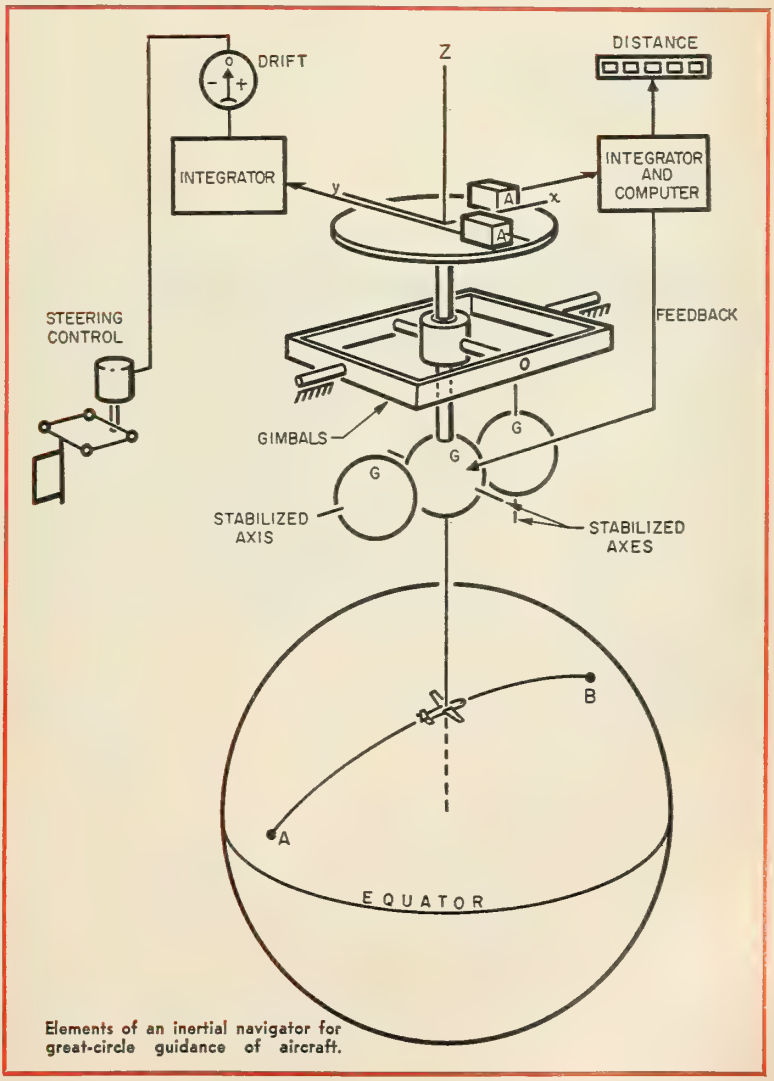
Inertial Guidance for Air Force High-Punch Missiles

Jam-Proof Guidance Has Come a Long Way But Accuracy Still Remains Big Problem

By J. M. Slater

Autonetics Division, North American Aviation, Inc.



INERTIAL GUIDANCE is the science and art of determining a vehicle's velocity and position and other quantities necessary for guidance, by measuring and integrating accelerations.

Inertial guidance is an absolute method, one which makes its measurements in terms of mass, length, and time—as interrelated in Newton's second law of motion. It can be a strictly self-contained system, not requiring any information from outside. Its ultimate accuracy is limited only by the degree of the instrumentation's perfection. In ballistic-rocket guidance the operation is primarily one of establishing the correct initial velocity (speed and direction) during the boost stage, for a trajectory or orbit which will intersect the target. All the guidance occurs in the first few hundred seconds, after which a "free fall" condition obtains.

The heart of the system in each case is typically a set of orthogonally disposed accelerometers capable of producing an output signal linearly proportional to acceleration (or to a time integral of acceleration). The accelerometers are mounted on a gimbaled, gyroscopically stabilized platform, to establish a fixed coordinate system unaffected by maneuvers of the craft. A computer integrates the accelerometer signals to determine velocity and position, and feeds back signals to the accelerometers, the gyroscopes, or both, for compensation of disturbing factors.

Aircraft Navigation

In Fig. 1 a stable platform is shown as part of a representative system for guiding an aircraft on a great-circle course from a point A to

Elements of an inertial navigator for great-circle guidance of aircraft.

a point B on the earth's surface. The accelerometers are disposed along course and transverse to course.

Any transverse acceleration—due, for example, to a cross-wind—is detected and integrated twice with respect to time, the second integral corresponding to distance off-course (drift). The rudder is controlled from the drift meter in the proper sense and amount to keep drift zero. In the case of a cross-wind the aircraft will thus be automatically pointed into the wind at the correct angle.

Longitudinal acceleration must be sensed and integrated to determine distance traveled. Now gyroscopes tend to remain angularly fixed in inertial space. Therefore in the absence of control, the gyroscope assembly would not follow the curvature of the earth as the aircraft moves from A toward B, and the longitudinal accelerometer would be progressively tilted backwards. This is undesirable, as a component of the acceleration of gravity would be sensed, and confused with acceleration of the craft. To prevent this, a feedback of single-integrated acceleration is provided as a control torque on the gyroscope which stabilizes about the transverse axis. With proper adjustment of scale factors in the feedback channel, the gyroscope can be caused to rotate (precess) in space about such transverse axis y, at exactly the same angular velocity as that of the aircraft about the center of the earth. Thus the accelerometer table is kept level.

A very important consequence of this feedback is that the system is given the properties of a long-period simple-harmonic oscillatory system. If scale factors have been properly selected, the oscillation period (as measured at a stationary point at the earth's surface) turns out to be equal to two-pi times the square root of the quantity: earth's radius divided by the earth's surface gravity (g). This is the so-called Schuler period, and one result following from its use is that acceleration errors do not yield a cumulative position error, but rather an oscillatory error.

So far, earth rotation has not been mentioned. It must be compensated, because the gyroscopes in themselves cannot distinguish between rotation of the earth relative to the aircraft and rotation of the aircraft about the center of the earth. In general some component of earth rotation appears on each gyroscope, and must be compensated. The computer applies control torques thereto, as a function of position along the course, to synchronize them with the rotation of the earth. Thus earth rotation is cancelled out.

Earth rotation, however, can still give rise to certain accelerations which do not correspond to changes in vehicle movement relative to the earth—the quantity of interest. Among these are centripetal acceleration associated with the earth's rotation angular velocity, which is sensed at the accelerometers even when the aircraft is stationary; also the horizontal component of the acceleration of Coriolis, which is a function of aircraft velocity as well as earth angular velocity. The total magnitude of these accelerations is usually at most only a few per cent of that of gravity. Compensations may be computed by the computer and applied as biases to the accelerometers to "blind" them in effect to these false inputs.

Ballistic-Missile Guidance

The operations in guiding a ballistic missile are closely related in principle to those performed in precision gunnery. In firing a shell the three predeterminable variables are inclination and azimuth of the gun and size of the powder charge, which last determines muzzle velocity.

In a ballistic missile the corresponding variables are inclination and azimuth of the missile and the velocity at time of cutoff of the rocket motor. After this point the missile follows a path determined by gravitational laws.

One can get a feeling for which variables are critical with the aid of a garden hose and nozzle. If it is held at an angle somewhere near 45 degrees, waving it up and down through a considerable angle will have negligible effect on how far the water goes. Swinging the hose sideways produces an aiming error. The same effect, amplified by the increased range, is present in ballistic missiles such that an aiming error of one milliradian—0.05 degree—produces an error of about one mile at a thousand miles. Equally critical in the garden hose experiment is manipulation of the valve to control the stream velocity.

The primary function of a ballistic-missile guidance system then is to insure that azimuth, inclination, and velocity at the time of rocket motor cutoff are correct for the given target. If it could be assumed that the missile would not be translated from a predetermined flight path in any direction by winds, unpredictable variations in motor thrust, or other agencies, during the powered portion of its flight, then it would be sufficient to set in predetermined values of these quantities.

Such a simplified guidance plan was actually followed in the early Ger-

Greater range & power for rockets & missiles

DEVISING a container for the highly corrosive fuels used in high-flying weapons and pilotless aircraft was almost hopeless until we discovered an amazing thing in our laboratory. Today, we are producing containers with bladders that are completely seamless. DuPont Teflon is the only material that responds to our Fluorlastic treatment and still retains the necessary toughness, flexibility, chemical inertness, high dielectric strength, low co-efficient of friction, to endure environmental extremes, ranging from —450F to 500F.

Manufacturers are invited to submit requirements for quotations

The Joclin manufacturing company 30 Lufbery Avenue Wallingford, Connecticut

Circle No. 42 on Subscriber Service Card.

man V-2 rocket practice. Azimuth and pitch were established with the aid of a set of gyroscopes analogous to ordinary flight instrument gyroscopes, and cutoff velocity with the aid of a single-integrating accelerometer or "velocity meter" (of gyroscopic-pendulum type) disposed along the longitudinal axis of the missile.

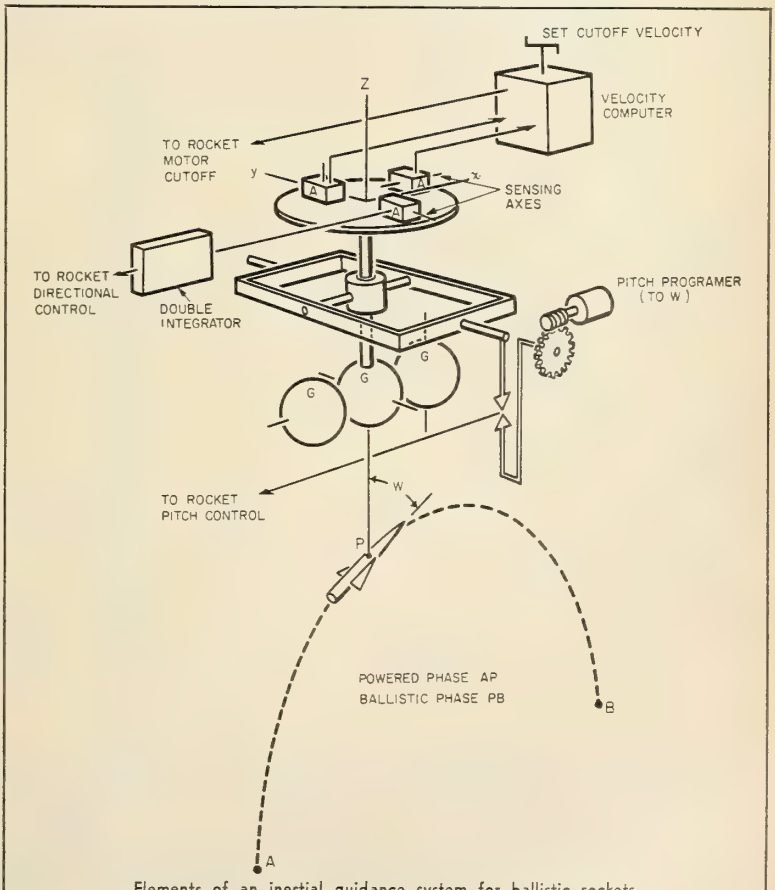
Such a scheme is of limited application, both because of unavoidable factors which could displace the missile from the intended guidance path and of the difficulty of making the accelerometer respond only to the desired quantity, acceleration along the flight path. The direct-mounted accelerometer will, of course, respond to a component of the acceleration of gravity g, which component is equal to g times the cosine of the angle equal to the instantaneous inclination of the missile to the vertical. This angle is difficult to predetermine correctly so that a sufficiently accurate compensation can be made.

For high accuracy a three-axis gyroscopically-stabilized platform could be utilized essentially similar to that described for flat-trajectory navigation, except for having a third, vertical accelerometer-integrator channel.

A somewhat idealized and simplified system of this sort is sketched in Fig. 2. Assuming for the moment a non-rotating earth, the platform is initially set, and thereafter maintained orthogonal to the vertical guidance plane through AB. The missile typically takes off vertically, and during the powered stage is rotated through some predetermined angle W—using the stable platform as a reference—toward the target B. The x and z-axis integrated-acceleration signals give components of the missile velocity vector. Rocket motor cutoff is initiated when the magnitude of this vector reaches a predetermined value. The lateral accelerometer signals are integrated and used in a drift-corrector in a manner similar to that in airplane navigation.

Actually, due to the fact that the earth is rotating, the missile will appear to an earth-fixed observer to be deflected laterally during the ballistic phase of the trajectory. To hit the target, the *initial* conditions must be set so as to give exactly the right "lead." This problem does not apply to aircraft navigation, where earth rotation is continuously compensated.

Although the present article is intended primarily merely as a sketch of principles, a misleading impression of simplicity might be gained unless some mention is made of the practical problems of instrumenting inertial guidance systems. These are some of the most severe in the whole field of engineering and manufacturing technology. The technique is based on force-balancing and force-measuring operations of the most delicate and precise sort, which must be carried out under non-ideal conditions.



The most critical problems are associated with the gyroscopes and the acceleration-sensing devices. This follows from the very nature of the method. Thus, the gyroscopes are used, not as mere magnetic-direction or gravity-signal integrators or as rate detectors, but as a fixed or basic sort of reference.

In aircraft navigation systems, drift (angular wander) of the gyroscopes can give a position error substantially equal to the drift angle multiplied by the radius of the earth. Gyroscope drift is caused by stray torques acting on the gyroscopic element proper. A typical gyroscope of size suitable for use in air-borne equipment might have an angular momentum of, say, one million gram-centimeter-squared-radian-per-second. Now the torque corresponding to a drift rate of one minute of arc per hour (approximately equivalent to one nautical mile per hour error buildup in an inertial navigator) is only 0.08 dyne-cm.

This torque is equivalent to the gravity moment exerted by the weight of he paper *within* this letter (o), cut out and stuck on the gyroscope gimbal at a half-inch radius from the axis.

The acceleration-sensing devices have much the same quantitative requirement as the gyroscopes, in regard to allowable disturbing torque levels, i.e., a fraction of a dyne-cm, typically. The problem here is relieved to the extent that mechanically simpler constructions are possible for accelerometers. But on the other hand the requirement for exceedingly linear integration over a wide range often necessitates incorporation of at least one stage of integration into the accelerometer, as in the gyroscopic-pendulum type, for example.

The fact that inertial methods of velocity and position finding have been carried to their present level of accuracy and reliability is a tribute to the foresight of the national defense authorities for initiating, subsidizing, and maintaining the requisite intensive development programs. It is also a tribute to the scientific, engineering, and manual skills of the personnel involved in such programs.★

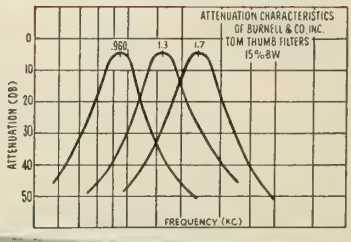
C	40 KC	S-60021	±15%	¾ x ¾ x 1⅜ H	1¼ oz.
D	52.5 KC	S-60022	±15%	¾ x ¾ x 1⅜ H	1¼ oz.
E	70 KC	S-60023	±15%	¾ x ¾ x 1⅜ H	1¼ oz.

Designed and tested to specification #MIL-T 26985



Supplied in two principal case sizes:

1. For RDB channels 1 through 6, case size is ¾ x 1½ x 2¼ inches high; weight: 4 ounces.
2. For channels 7 and up, case size is ¾ inches square and 1⅜ inches high; weight: 1¼ ounces.

These cases are generally equipped with a 4-pin plug to match the small Winchester socket.

ATTENUATION CHARACTERISTICS

Impedance: 100 K ohms in and out.
Insertion loss: less than 6 db.
At ± 7.5% band width is less than 3 db.
At ± 25% band width is greater than 15 db.
At 1.75 f attenuation is 40 db or more.
At .57 f attenuation is 40 db or more.

Human Engineering in Weapon System Development

by David W. Atkins,[1] David M. Piatt,[2] Albert Shapero[3]

IN THE DEVELOPMENT of a weapon system, the role of human engineering is to optimize the man-to-man and man-to-machine relationships within the system. This has developed from a growing realization in the weapon system field that inadequate consideration of the human components in the system (operators, maintenance men, etc.) can mean marginal operations or failure of the system.

The human engineer's tasks are based on his specialized knowledge of the characteristics, capabilities, and limitations of the human as a component. Basically, these tasks are:

1 Determining the best distribution of functions between man and machines according to their respective inherent capacities and capabilities.

2 Assuring the optimum communication between man and man, and man and machine by the proper selecting, positioning, and linking of the men, equipments, and environments.

3. Assuring equipment designs which are optimized for ease of installation, maintenance, and operation.

4. Determining manpower and training requirements and evaluating human performance in the over-all system operation.

These tasks begin with the earliest phase of the weapon system development program and continue into its final evaluation stage. A fuller understanding of what the tasks are, what is involved in their implementation and their possible effects upon the program is of value to all who are connected with the management and implementation of weapon system development and operation.

Distributing Functions Between Men and Machines

Ordinarily design decisions are made on the basis of materials, components, and "state-of-the-art" electromechanical design techniques without any regard to the characteristics and capabilities of the human components of the weapon system. This failure to properly assay the role of the human component results in what can be called the accidental distribution of functions between men and machines.

Optimum as opposed to accidental distribution of functions between men and machines requires full consideration of which functions are inherently performed better by either men or machines, the economics of this distribution, and safety as well as the mission, electro-mechanical data, hardware availability, design limitations, and the other usual considerations. When men and machines are considered together there is a direct payoff in increased system operability and effectiveness which minimizes expensive design changes, operating errors, and operating and maintenance costs.

Psychological and physiological data, which make up the bulk of the human engineer's working material are utilized in making decisions in assigning functions to men or mechanisms. For example, by using this data the following general statements can be made:

SENSORY ABILITY: Except for the most complex instrumentation, human audio and visual sensing capacities surpass those of machines.

PERCEPTUAL ABILITY: Man excels at comprehending complex data.

ATTENTION: By being alert for changes, human beings can often anticipate undesirable conditions.

FLEXIBILITY: Humans are characterized by a flexibility of action which provides insurance against complete equipment system failure.

MEMORY: Man is more efficient in tasks requiring long-term memory.

JUDGMENT AND REASONING: Men are needed to make judgments when it becomes impossible to reduce operations to logical preset procedures.

SPEED AND POWER: Machines can make movements more smoothly, quickly, and powerfully than man.

REPETITIVE OPERATIONS: Machines excel in repetitive and routine tasks; unlike humans, machines do not become bored or inattentive.

COMPUTATIONS: Machines designed to perform specific computing operations are more efficient than man.

SIMULTANEOUS ACTIONS: Machines can be devised to carry on a greater number of simultaneous jobs than man.

There are two aspects to the economics of distributing functions to men or machines which demand consideration. First, there is the initial cost of the system. Secondly, there is the continuing or operating costs in the field. Building into machines functions that are normally associated with human abilities usually involves design complexity that increases the design and production cost. This must be balanced against the savings this design can effect in the operating costs in the field. Consideration of the economics involved in simplifying operations at the cost of increasing the maintenance burden can strongly influence design decisions as to whether a function should be performed by man or mechanism. For example, the decision to make a piece of equipment self checking has resulted in the ludicrous situation where the complex self maintenance features of the equipment required as much maintenance as the operating features of the equipment.

Safety and Cultural Considerations

Every society imposes conditions and limitations upon treatment of human beings. These are a function of the culture and must be taken into account by the human engineer during the design of the weapon system. Often this is done by designers without conscious examination of the problem. Among these conditions and limitations are those associated with safety, body usage, and instrument design.

During World War II, Russian fighter pilots extensively employed aircraft ramming tactics in combat. In addition, the Russian Air Force had the armor plate removed from American aircraft delivered to them to increase the aircraft performance at the expense of pilot safety. In both cases, American attitudes toward the value of the individual significantly affected flight tactics and consequently aircraft design. The deliberate expenditure of a pilot's life as part of weapon system design was also employed by the Japanese in World War II. The use of man as this type of guidance system would be unacceptable to all Western cultures despite the calculated payoff.

Cultural reading habits would dictate that the typical Western nation instruments arrangement should probably be from left to right and top to bottom. However, such a scheme would not be optimum for Chinese, Arabic,

[1] *Supervisor, Human Factors Group, Radioplane Co.*
[2] *Litton Industries*
[3] *Supervisor, Weapons System Operations Section, Radioplane Co.*

or Israeli operators whose lifelong reading habits condition them to reading and writing (and thus scanning) in different directions.

The use of the human body for operating or sensing tasks also is limited by the taboos and practices of the society. For instance, our culture would not accept the use of radical surgery or prolonged and habitual use of dangerous drugs to increase the utility value of a human component.

Linkage Between Man and Machine

In the past it has been a rather common belief that a man could operate almost any kind of equipment. Little thought was given to the physiological and psychological capacities and limitations of the humans charged with the operation and maintenance of complex systems. As a result the operator is generally provided with displays and controls designed primarily to engineering criteria which ignore his limitations.

When men and machines are required to work together it is important that the machines provide required information in such a way that the human operator can make an exact interpretation. The information transmitted by the machine to the operator must permit him to make required judgments and to act quickly, decisively, and correctly. This means that the design and placement of indicators and controls must be on the basis of the real capabilities of the operator rather than on theoretical capabilities. Some data can be much more readily accepted than others. Humans are also capable of producing a wide variety of control outputs, but again, they perform some much more rapidly and accurately than others.

In dealing with the complex tasks involved in operating weapon systems, it is obvious that even if the human operator could correct an error, there might not be time for secondary actions. The sequence of many operations is complex, precise, and in its final steps, irreversible. Thus, it is of prime importance that judgment errors are minimized by designs requiring only those human decisions which can be made correctly and within the required time limits. Good human engineering makes it possible for the operator to act decisively, selectively, accurately, and quickly. It further assures design of the human requirements with regard to the learning capability of the personnel who are to operate and support the weapon system. Thus the operator is only required to do things that he can be taught to do reliably.

It is probable that in most weapon systems of the foreseeable future, control functions will be performed primarily by humans or there will be semi-automatic control supplemented by human performance of certain critical functions. In either case the linkages between man and machine will be rather complex. These man-machine linkages have two main forms—displays which communicate data from the machine to the man, and controls which communicate instructions from man to machine.

The Human Element

In a man-machine system displays are used to present information to the human element. Usually, this is done through either the visual, auditory, or tactual senses, or some combination of the three. The best type of information display is the one which cuts the lag in perception to a practical minimum. That is, the data inputs to the human operator must be such that they can be readily accepted and interpreted.

Once the necessity of presenting certain information content to the operator has been established, the human engineer is guided in the selection of the type of display by many considerations. For example, in deciding whether to present information visually or auditorily the human engineer knows that, in general, the eyes are a better medium when it is necessary to present relational or other complex information. On the other hand, the ears are a better sensory medium when dealing with (1) alarm signals, (2) displays where reaction time is important, and (3) where information input is low but continuous.

Auditory Radar

In the past, most information has been displayed visually for equipment operators. In many cases this has resulted in an overloading of the visual senses. Further, some of the more recent investigations indicate that some information now presented visually could just as well be presented auditorily. For example, techniques have been developed at the Air Force Cambridge Research Center for effectively presenting certain types of radar return information through earphones rather than displaying it on a scope.

The human operator directly affects the weapon system through the operation of controls. The best controls are those which minimize the probability of operator error and which permit the operator to transmit the proper action with ease and speed. Hence, in fulfilling his role of optimizing human performance, the human engineer must insure that equipment controls are designed so that they most effectively transmit the operator's intentions.

Servo Engineers Work where your

training and experience can be fully utilized:

in **High Thrust Rocket Engines**

The spectrum of servo work at Rocketdyne is very broad: electronic, mechanical, hydraulic, pneumatic. New approaches...new methods...new materials...must be constantly explored. That's part of the extreme interest of the work. This is a place for the man who is strong on systems analysis.

Your assignment will be the Mixture Ratio Controls, Thrust Controls, and Pressure Controls that govern the performance of the most powerful engines man has ever devised. They must cope with changing mass as fuel is used up, withstand conditions of heat, cold, G, lapse of atmospheric drag, vibration, varying combustion efficiency. Precise control of the power plant is mandatory in order for the guidance system to accomplish its mission.

You won't be bogged down in routine at Rocketdyne. You'll be able to concentrate on analyzing completely new problems and coming up with the answers...and on gaining valuable new experience in an advanced servo field. Write: A. W. Jamieson, Rocketdyne Engineering Personnel Dept. MAR-4, 6633 Canoga Avenue, Canoga Park, California.

ROCKETDYNE

A DIVISION OF NORTH AMERICAN AVIATION, INC.

BUILDERS OF POWER FOR OUTER SPACE

Considerable work has been done in the past on such problems as the design and arrangement of visual displays controls, designing control systems in which non-linear relations between controls and displays are used to meet wide variations in speed and accuracy requirements and coding of controls to facilitate identification.

For example, it has been found possible to code controls by shape so that even with gloves on, an operator can immediately tell which knob he is touching without having visual access to it. Efforts are now under way to standardize certain of these shape codings for various functions on different pieces of equipment.

Usually it is necessary to consider display and control problems concurrently, since equipment operators customarily receive information from displays, process it, and respond by initiating control movements. In maximizing this behavior cycle the human engineer applies his knowledge of human perception, higher integrative mental processes, and characteristics of motor behavior.

Man-Man Linkage

To fully utilize the human component and integrate him into the weapon system it is necessary to consider not only the interrelationships between man and machine but also those between man and man. When men perform as a team or when information is transmitted and received directly from man to man within the system operations, it is the human engineer's task to see that the design is such that these operations are designed with regard to man's capabilities.

Optimum Design for Maintenance

Maintenance problems demand consideration during initial equipment design. It is both possible and desirable to engineer equipment for maximum usefulness and minimum maintenance. Human engineering's aim is to achieve a design that is optimized not only for operability but maintainability also.

In discussing the assignment of functions to men and machines earlier in this article, the importance of maintainability factors was mentioned. It is recognized that when human functions are mechanized, the complexity and maintenance requirements may be increased. Similarly, in determining test requirements for equipment, a balance is struck between mechanizing of test and self-test functions, and the burden of tester maintenance imposed by the complexity of its own functions.

On the other hand, the capabilities and limitations of the human are essential considerations in determining maintenance tasks, component accessibility tools, techniques, test equipment.

Maintenance involves a certain amount of decision making, such as: What unit is malfunctioning? What should be done to correct this malfunction. Can the required operation be successfully completed despite the malfunction? The factors involved in making such decisions are so complex and unpreditcable that at the present time humans are generally much better able to make them than are machines.

Manpower and The Basic Training Requirements

The human engineer is directly concerned with the determination of the requirements for weapon system manpower in terms of types, skills, numbers, and training.

While the ability of human beings to accept data, make decisions, and manipulate controls can be modified by training, lengthy and expensive training programs are not the proper or economical method to compensate for poorly designed controls and displays. However, the design of displays and controls together with many other factors determine training requirements for bringing operators and mechanics to the desired level of performance.

In establishing training requirements, the human engineer considers every task to be performed in the installation, operation, and maintenance of the weapon system. The tasks are then grouped and positions or jobs are defined. On the basis of previous knowledge and assumptions about the capabilities of the personnel who will fill these positions, training requirements can then be established. Here the human engineer utilizes his general psychological background and his specific knowledge of learning theory.

In the area of training methods and devices the human engineer determines what parts of complex tasks must be trained realistically rather than by simulation methods, and how training devices can be simplified by eliminating hardware which is not needed for efficient training.

Machines can be designed to be simple to operate regardless of their inherent complexity. The tasks of men and machines can be analyzed and properly separated to reduce the error exhibited by either. Malfunctions can be minimized by considering the malfunction problems from the beginning rather than at the end of the development of a piece of equipment. ★

LEARN and EARN

. . . Air Force looks to Systems Labs for unique program to keep the U.S. supplied with rocket engineers

by Fred S. Hunter

SYSTEMS LABORATORIES CORP., incorporated only last May, already is a million-dollar-a-year business, and the work load on the president's desk keeps increasing.

This may mean that its president, Dr. John L. Barnes, who teaches two engineering classes at the University of California at Los Angeles, will have to cut—reluctantly—to one.

But no matter how great the flow of papers across his desk at Systems Labs, Dr. Barnes will devote some portion of his time to the classroom.

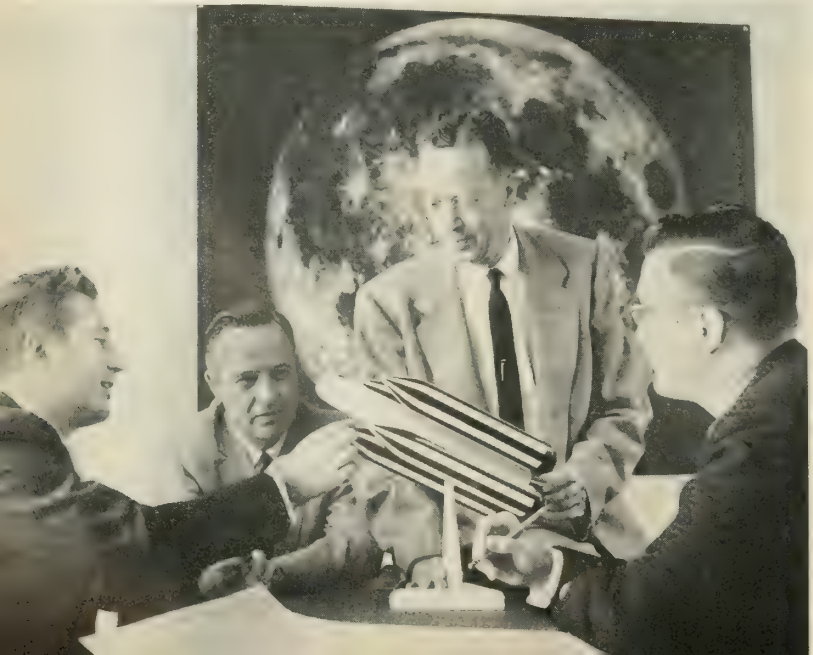
"Continuing to teach is a way to keep in touch with your engineering," said Dr. Barnes. "Otherwise, next thing you know, you are 100% management." Dr. Barnes wants to be sure to retain his identity as a scientist.

Systems Labs has a number of distinguishing features: it is the first scientific corporation of its kind to specialize in interplanetary space travel, research and development; it is owned and managed by the scientists and engineers who comprise its staff; a scholastic atmosphere pervades throughout its operation.

It probably has a higher percentage of Ph.D's on its payroll than any comparable institution in the country. It also has a graduate honors program that puts the company in something of a class by itself.

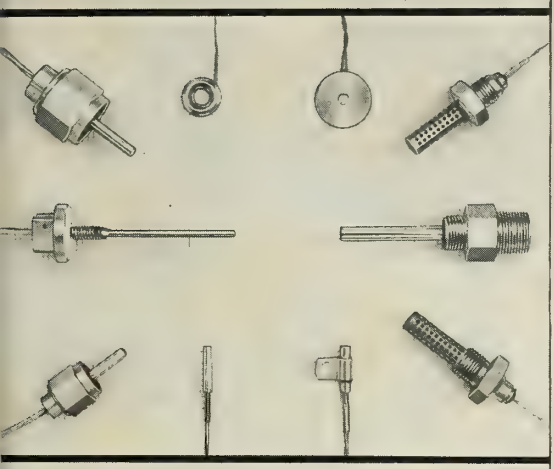
A number of large aircraft corporations are offering scholarships and other educational assistance to graduate engineering students to pursue advanced degrees—and as an inducement in personnel recruiting—but no small companies have felt able to undertake the expense until Systems Labs came along. It's indicative of the imaginative characteristics of Systems Labs' activities that close to 500 applications were received by the company from graduate students in the U.S. and abroad within a month after Dr. Barnes announced the fellowship program.

Systems Labs' scholarship program provide full tuition, books and supplies at one of the three graduate schools in the Los Angeles area, the University of Southern California, the University of California at Los Angeles and California Institute of Technology. It is open to graduate students in the physical sciences, mathematics and engineering, who are in the top 10% of their class. Science bachelors working for masters and masters seeking doctorates are eligible. A graduating senior may continue his education right through to a Ph.D. under the program.



Candidates are put on salary as soon as they arrive and work full time at Systems Labs during the summer. During the first semester, 80% of their time is devoted to study, 20% to work; during the second, 40% to work and during the third 75%. Starting salary is stepped up four times during the full course of the training program.

Each student is assigned to a "staff mentor"—one of Systems Labs' top scientists or engineers, and works closely with him during the training program. Upon completion, the candidate is free to continue on Systems Labs' professional staff or seek a position with another company.



One of the world's leading authorities in electrical engineering, and co-author of "Transients in Linear Systems," the standard text in the field, Dr. Barnes is especially aware of the importance of "feed-back" in the complex circuit of human relations in scientific research and advancement. "Top quality people in an optimum environment turn out the best research," he explains. "You can't keep people unless you learn what they want."

Systems Labs' can be described as a small company with big objectives. "We don't want to get too big," says

President J. L. Barnes briefs Systems Labs staff members on moon rocketry. Left to right: R. H. De Lano, Electronic Weapons Systems Coordinator; Dr. Lewis Larmore, Superfrequency Sensors Director; Dr. Barnes and Dr. J. A. Marsh, Radiofrequency Sensors Director.

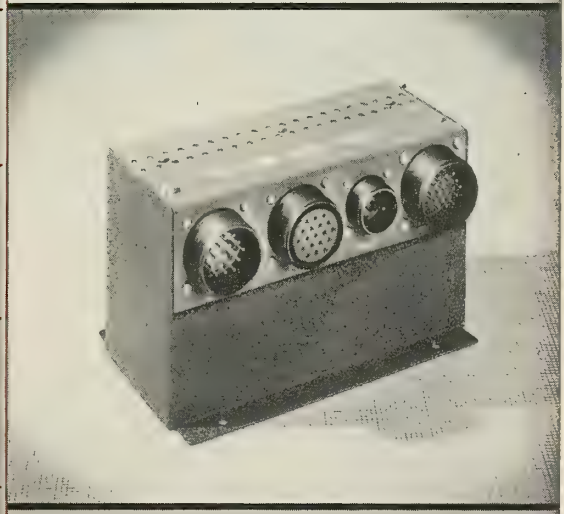
For the highest degree of *Accuracy*
in AIRBORNE TEMPERATURE INSTRUMENTATION

HIGH OUTPUT • RESISTANCE-TYPE TRANSDUCERS

Arnoux high resistance temperature probes are designed for telemetering and other applications requiring high signal levels. Models are available in a wide variety of physical configurations for measuring surface, fluid, and air temperatures.

- Output up to 5 volts without amplification.
- −320°F to +500°F range with ±2% linearity. (Special units are available up to 1600°F.)
- Nominal resistance values: 100 to 20,000 ohms.
- May be used in AC or DC Bridge circuits.
- Meets MIL-E-5272A specifications.
- Calibration curve supplied with each probe.

When used with ARNOUX miniaturized companion "TME" system, 20K transducers provide 5 volts output for as little as 150°F change.



Write for Bulletin 300

MINIATURE MULTI-CHANNEL TEMPERATURE MEASUREMENT SYSTEM... full scale output 5 volts

ARNOUX "TME" is a completely self-contained system designed for operation with ARNOUX special resistance-type transducers. Models are offered in 7, 14, and 20 channel capacity. The unit contains two precision mag-amp type, regulated D.C. power supplies, series connected with common neutral, for excitation of the transducers in half bridge circuitry.

- Power requirement: 115 volts, 400 cps.
- Power consumption: 20 channel model requires less than 20 watts.
- Balance and attenuation controls for each channel.
- No vacuum tubes or transistors used.
- Output voltage and impedance characteristics — directly compatible with F.M. sub-carrier and P.W.M. coder input requirements.
- System stability: within 1% throughout MIL-E-5272A environmental.
- Dimensions: 20 channel model: 7" x 4¼" x 3", wt. 5½ lbs.

LOCKHEED AIRCRAFT CORPORATION

PALO ALTO • SUNNYVALE • VAN NUYS

CALIFORNIA

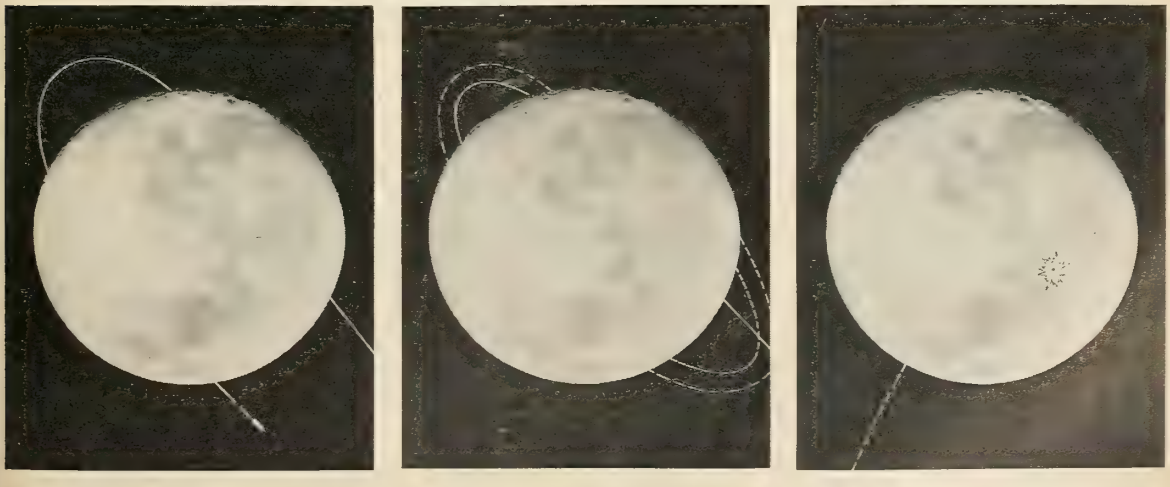
Dr. Barnes, even though he admits bigness is of itself often an advantage. "You can get contracts on bigness alone," he points out.

It will take $15 billion to circle the moon—one of Systems Labs' big objectives. This means, of course, that no agency other than the government can finance it. But, as Dr. Barnes points out, this is not the kind of project you undertake in one chunk. It is something to be done a few millions—or billions—at a time.

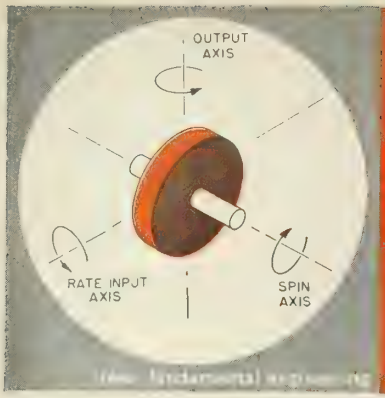
Systems Labs charter states that the corporation was organized primarily to work on interplanetary travel. Meanwhile, it is bringing in its revenues from sub-contracts. At this writing it has 15 of these, all scientific projects. Included in the first sub-contracts obtained by Systems Labs were four from Republic Aviation to solve problems in guided missiles and aircraft fire-control.

Systems Labs expects to begin getting some prime contracts very soon. They may even be in the interplanetary field. Dr. Barnes hints that more than one government agency is beginning to look in this direction.

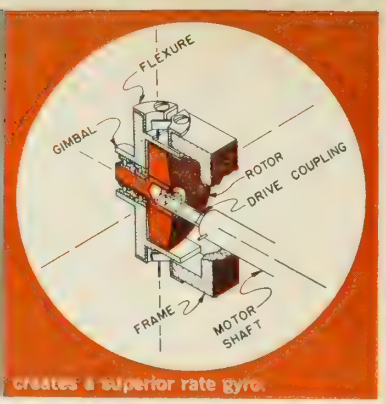
As Systems Labs' grows, Dr. Barnes plans to partition it off into semi-autonomous sections. He envisions a number of separate laboratories at various points on the west coast, Santa Barbara, LaJolla, Corona del Mar, perhaps even in other sections of the country. Dr. Barnes wants a ceiling of 100 employes in any one section. Better communications and better work are the twin accomplishments of groups held to a maximum of 100, he believes.



The first separate laboratory probably will be a radar antenna laboratory. This is logical because he has the man to head it up, Dr. James A. Marsh, who, says Dr. Barnes, is a good scientist and also a good administrator. Formerly head of North American Aviation's radar group at Downey, Dr. Marsh is one of the founders of Systems Labs. Another is Richard H. De Lano, one of the co-holders of the *Falcon* missile.



Dr. Barnes and his associates believe interplanetary travel will actually be easier than generally expected. The numbers, they say, are all coming out right in Systems Labs' initial studies of the various phases. They're watching nuclear power developments closely and unless there are unexpected throwbacks here Dr. Barnes doesn't think it at all optimistic to say that the next few years will see the development of a practical moon rocket project. ★



Dr. John L. Barnes, President of Systems Labs which weans students slowly from the classroom to the laboratory working up from a 20 per cent work-day to 75 per cent in the last year.

Three methods man may employ in trying to get his first closer look at the moon—around and back; up and orbit; and a visible impact on the moon's surface. Any one of these is the kind of project Systems Labs was set up to develop. It is also the kind of a project AF's Western Development Division is preparing to launch.

creates a superior rate gyro.

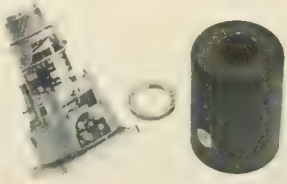
New 'SW' Rate Gyro

Simplicity delivers superior performance

Fundamental engineering and precision manufacturing team up to enable new Humphrey *SW* Rate Gyros to deliver superior performance. More rugged ... more dependable ... greater precision for the most demanding applications in advanced missile and aircraft systems.

Simplicity of design eliminates unnecessary parts. Heart of the *SW* Rate Gyro is the solid rotor inertial element mounted on precision radial thrust bearings in the exclusive bridge-like gimbal. Two unitized steel flexures give pivot and spring-restraint functions attaching gimbal to frame.

Using compatible materials and high-G centrifuge balancing adds to superior performance qualities. No deterioration of the *SW's* performance even under the most severe environmental conditions. Operates in temperatures from −65° F to ±185° F; vibration at 10G from 20 to 2,000 cps; and shock to 100G.



Four basic sizes provide choice of drive motors and pick-offs to avoid any compromise in your system design.

Minimum number precision parts: solid rotor; exclusive coupling, flexures.

Simple sub-assembly: one compact unit; motor separate from sensing element.

Floating-piston constant-action dry-air damper; effective pressure-sealed case.

ICBM Won't Replace Manned Bombers

Air Chief Marshal Sir Dermont Boyle, the Royal Air Force's Chief of the Air Staff, stated in Australia last month that intercontinental ballistic missiles would never completely replace the manned strategic bomber. The primary problem of all modern aerial planning centered on the change from manned aircraft to guided missiles, he declared. Some authorities thought the change would take place overnight, others that it would never take place.

Meanwhile the Chairman of Bristol Aircraft Ltd. and President of the Society of British Aircraft Constructors, C. F. Uwins, who was also visiting Australia, urged in an interview that some of the secrecy surrounding British guided missile development should be lifted. He said this would have a very good effect on the morale of guided missile workers.

Uwins revealed that more than 400 British companies are now working on guided weapons, including long-range ballistic missile.

Oil Spraying Rocket For Mercy Missions

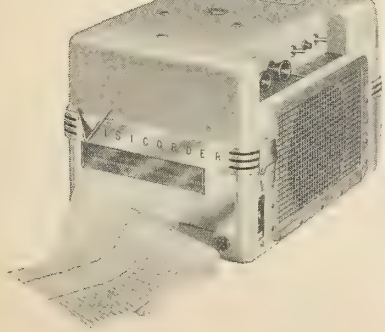
From Bremen, Germany comes news of rocket development for mercy missions. The Deutschen Arbeitsgemeinschaft fuer Raketentechnik has designed two models of an "oil-spraying" rocket for reducing the heights of waves around a vessel in distress. In principle, the rescue ship (Coast Guard) would fire a series of these rockets up wind of the disabled vessel to lay down an oil slick prior to rescue. The rockets are designed to be fired from the standard rescue-line throwers. Only prototypes have been manufactured so far and tests are anticipated.

French Determine Fuel Erosion Constants

The French have come up with novel ways to determine the erosion constants of solid propellants. One method used two nozzles with a progressive burning grain—a large steel nozzle to maintain pressure and a smaller nozzle to test the propellant. Another method uses an erosion bomb which compares two grains.

Yet another French work tackled an old propellant—black powder for rockets. The exponent of burning rate was about 0.62 at pressures up to 800 mm Hg. At atmospheric pressures, the fastest propellant had a burning rate of 0.46 in/sec and consisted of 5% S and 20% C. For smoother low pressure operation, the best composition was found to be about 25% S and 20% C.

all at once...



the HONEYWELL VISICORDER®

directly records six phenomena at frequencies from DC to 2,000 cps

The versatile Visicorder will fit almost unlimited oscillograph applications where instantaneous monitoring and direct recording at high frequencies are needed.

The Visicorder is the only oscillograph that records directly at frequencies up to 2,000 cps, and at sensitivities comparable to photographic-type oscillographs. No peaked amplifiers or other compensation of any kind are needed. The record requires no liquids, vapors, powder magazines or other processing materials.

Deflection is six inches peak to peak, covering the full width of the chart. The D'Arsonval-movement mirror galvanometers, in your choice of natural frequencies will, of course, overlap their traces; they are not limited by adjacent channels.

Let your nearest Honeywell Industrial Sales Engineer tell you more about how the Visicorder fits *your* application. Call him today.

International Scene

By Anthony Vandyk

Naval minesweeping techniques are used in a missile recovery system developed at Australia's Woomera range. Designed to protect valuable test missiles and their delicate instruments from damage, it employs a long cable attached to and reeled out from an aircraft. At the far end of the cable is a winged paravane which flows like a kite 400 to 500 ft. from the side of the aircraft. The missile is equipped with a small parachute which is automatically or electronically released at the end of its run. This parachute is not big enough to support the missile in the air but it checks its falling speed. The aircraft then closes in and sweeps the cable of the aerial paravane across the cable of the parachute. The parachute cable slides along it until grappled by the paravane. The recovery point is another cable slung at the top of a ravine or between two towers. It collects the missile from the paravane as the aircraft flies past. m/r's Australian correspondent comments: "This development calls for rather tricky flying!"

•

Rolls-Royce is building the North American Aviation rocket motor under license for use in Britain's IRBM. Work on this project has been in progress for some four years. Meanwhile the British Army is putting final touches for plans for the use of its U.S.-supplied *Corporals*. Present indications are that the English Electric Company will handle the overhaul of the Corporal in the U.K.

•

It's no secret that the Royal Air Force thinks very highly of infra-red missiles and is counting on the de Havilland AAM of this type to play a major role in the air defense of Great Britain. One reason that infra-red missiles are preferred to radar-guided types is that the former are less susceptible to jamming.

•

"World-wide circulation" is being given to a notice by de Havilland Propellers Ltd. that this company is responsible for the de Havilland guided weapons program—not the de Havilland Aircraft Company. The propeller company is one of three operating companies (Aircraft, Engine and Propellers) within de Havilland Holdings Ltd. in Great Britain. In Australia the propeller company has set up facilities at Salisbury and Woomera with administrative assistance from de Havilland's Australian subsidiary, de Havilland Aircraft Proprietary Ltd. De Havilland-Canada has established its own Guided Weapons Division with the assistance of de Havilland Propellers Ltd.

•

The Royal Air Force has formed special units to conduct service acceptance trials of missiles under the control of the Ministry of Supply. RAF men for these units are attached to manufacturers during the development stage. After acceptance trials they will carry out the service trials of the weapons in the RAF. In another phase of missile work the RAF has formed its first guided weapons training station. A simulator is being built at this facility (location secret) which can synthetically reproduce attacks by enemy aircraft and enable interceptions to be practiced under realistic conditions.

•

The Paris International Air Show May 24-June 2 will be used to unveil a lot of new French developments in the missile field. It is probable that SNECMA will be able to reveal some details of its work on ramjets. SNCA du Nord is likely to have plenty of missile hardware on show. The show is held at Le Bourget airport and has representation not only from French manufacturers but from nearly every European country plus Canada and the U.S. Several of the East European countries are planning to participate.

MICROWAVE AND ANTENNA ENGINEERS

Experienced microwave engineers are required to perform research, development, and design on antennas, radomes, and microwave components. System engineers are needed for system development related to microwave receivers, Electronic Reconnaissance, Countermeasures, Radar and Transponder Systems. The work will be accomplished in the Radiation Laboratory in relation to prime missile and airframe contracts.

AUTOMATIC CONTROL SYSTEM DESIGN ENGINEERS

Engineers are required with experience in closed loop stability analysis and synthesis of automatic control systems. System engineers are needed for design and development of servomechanism, memory circuitry, digitalanalogue techniques, and numerous other control equipment for fulfilling the requirement as specified by system analysis design studies. These engineers will perform research, development and design of stabilization and control systems for guided missiles and high performance aircraft prime contracts.

AIRCRAFT ELECTRONICS ENGINEER

Engineers with experience in transistor applications, pulse and video circuits, servomechanisms, general circuit design, guidance and radar system analysis, audio circuits, electro-optical transducers and optics are needed to perform system and detailed circuit design on guidance, radar, and television systems for guided missiles and high performance aircraft.

TELEMETRY ENGINEERS

Electronic Engineers having design capabilities and experience with present airborne and ground telemetry equipments, system design requirements, and detailed familiarity with data reduction techniques, calibration of end instruments, converter techniques, and intervalometers are needed in relation to prime missile and airframe contracts. Ground floor opportunities exist for competent personnel in this field.

Tiny, Tough and Terrific!

New TDI Type 1202A Voltage Controlled Oscillator*

Actual Size of Unit (Height: 3¾", Width: 1 15/16", Depth: 1 1/16", Weight: 8 ounces).

*Pat. Pending

This new TDI voltage-sensing subcarrier oscillator weighs in at only 8 oz.—is approximately one-half the size of previous oscillators—contains only two tubes, compared to present day five-tube circuits—but these are no indication of its outstanding performance! Reliability under typical (and that means extreme) environmental conditions is nothing short of amazing.

Interested? You can learn more by sending today for free technical data and detailed specifications of TDI's newest precision component for in-flight telemetering. Bulletins of other TDI remote instrumentation products sent on request.

BUILT FOR ENDURANCE!

TEMPERATURE—Designed for operation from −65° C to +100° C

ALTITUDE—Center frequency stability within ±1% of design bandwidth with variation in altitude from sea level to 80,000 feet (temp. constant)

ACCELERATION—Center frequency stability within ±1.0% of design bandwidth under constant acceleration of 50g in each direction of each major axis

SHOCK—Center frequency stability within ±3% of design bandwidth after being subjected to 60g, 10 millisecond duration impact shock in each direction of major axis

VIBRATION—Center frequency stability within ±3% of design bandwidth when subjected to sweep vibration of 0.06 inches double amplitude from 10 to 55 cps and 10g from 55 to 2000 cps (three minute duration total) in each major axis. Noise output less than 3% peak to peak of DBW

TDI's newest office is now located at 305 Washington Avenue, SE, Albuquerque, New Mexico

World Astronautics

By Frederick C. Durant III

For the next 5-10 years the unfolding of satellite vehicle research programs will represent the next major step in the development of astronautics. Soon the first handful of 20 in. NRL telemetering spheres will be flung into satellite orbit around the earth as part of the U.S. IGY program. The USSR, too, will launch IGY satellites of size and orbits still to be announced. As discussed previously in this column these initial programs will be followed by satellites of increasing dimensions. Eventually, man will travel in satellite flight.

To report clearly to the public on these events will require a depth of perception that is not common in news agencies today. Understanding and appreciating the satellite program's significance will be necessary to properly tell the story to the public.

Executive elements of our news and communications media must become educated to the fact that space flight can no longer be treated in a tongue-in-cheek manner. This approach, widespread until recently, masked a lack of understanding of what space flight was all about. But astronautics has now reached the age of respectability. Industry and Defense Department attendance of the Convair-OSR symposium last February significantly underlines this fact.

The problem of lucid commonsense reporting and interpreting such news events as the *Vanguard* test launchings and subsequent live firings is facing all news editors. To meet this challenge every major radio and TV network, wire news service, newspaper chain and news periodical should be undergoing self-education. At least one or more responsible staff members should now be charged with the responsibility of learning the basic facts of astronautics.

The public is understandably confused about space flight. There is deep interest but there are many misconceptions about the relative size of the problems and probable time table of realization. Above all, they want to know the *why* of space flight. What will astronautics mean directly and eventually to the man in the street, to scientific research, and to industry? When, and how, will astronautics affect our economy?

The rocket and guided missile industry and the professional societies have a major responsibility in providing facts and understanding through popular lectures, brochures, films, and consultancy. There have already been excellent examples of these such as Martin's booklet, "A Moon is Born" or their film "Horizon Unlimited," or G.E.'s "Rocket Facts." However, the quantity of such material is still far too small in the face of the rate of rocketry progress.

In the course of talks on rocket power which your columnist regularly gives to professional society gatherings it is still startling to find that discouragingly few persons know what the letters IGY represent. Still fewer can tell you why the e.s.v. program is revolutionary, or what it portends. As for the man in the street, the level of knowledge is still lower. And yet the subject relates to the most exciting adventure and exploration expedition to be undertaken by civilized man. The majority of people now alive will witness manned space flight and, at least, lunar expeditions in their lifetimes.

The communications media have the opportunity to provide the public with a sound understanding of the next basic steps in satellite flight achievement. More than an opportunity, it is a responsibility.

ENGINEERS, SCIENTISTS:

What did they say the last time you had an

IDEA?

At Decision, we talk to hundreds of engineers, and many report how frustrating it is when they make a good constructive suggestion and are gently reminded that "ideas" are the responsibility of others. (Strangely enough, these same companies often talk about "creative engineering" in their recruiting ads.) Fortunately this attitude is not typical of most progressive companies today.

We know many companies who encourage and appreciate creative thinking . . . who know that youth, inspiration and progress all go together.

Whether you're thinking seriously about changing jobs or not, Decision can improve your job perspective *confidentially* and at no cost to you. We will send reproductions of your resume (without your name) to the hundreds of top ranking firms—our clients—who pay us to find good men. And, we will enter your name and resume in our unique Decision/Register, which we search daily to find engineers for specific job openings.

The Ballistic Missile Challenge

. . . as seen by Major General Bernard A. Schriever

Chief, Western Development Division of ARDC

Q. *General Schriever, does the management organization here at WDD function as one team?*

A. Yes you can't really distinguish organizational lines between WDD, R-W and BMO. It's one integrated operation. We work as one management team. Not that we don't have problems from time to time, we do; but to all intents and purposes we function as a closely knit team. I have more problems internally within my own staff than I do in keeping the R-W, BMO, and WDD all working together.

Q. *I notice everyone wears civilian clothes. Why is that?*

A. There are really two reasons for it. The first one has to do with security. When we first came out here we felt that to enter into a civilian community and have a lot of officers running around would immediately create speculation which we felt not in the best interests of security of the program of the Air Force. That was reason number one.

Reason number two is that we feel that everyone working in civilian clothes actually creates just a little better spirit of harmony or establishes conditions where you can work in better harmony. If I were sitting here with two stars on every day, I think the people coming into my office would be just a little bit more apt to be formal and stiff than if I'm sitting with a sports jacket on and a pair of brown trousers.

Q. *Is it true that $470 million have been spent on test facilities since the program was accelerated in August 1954?*

A. Well, not just test facilities, this includes plant expansion, too. Let's take the North American Rocketdyne plant at Canoga Park as an example. The plant that was built in Denver by Martin is another. So is the plant that is being built right now by Convair. However, the largest percentage of this total of $470 million has been for test facilities—major test facilities—and also test equipment which you never see.

It's an environmental type of test equipment; shake tables, centrifuges, furnaces of different types, shock tubes and things of that nature which are small but expensive. They are the kind of things that we have to have to start testing the reliability of the components before they are assembled into a subsystem. Then, of course, facilities get larger when you start testing subsystems. When you start testing the entire missile with the subsystem assembled then they become quite large.

I think a comment on the test facilities and their possible use for follow-on program would probably be an interesting point as well. You take the North American test stands that we have at Santa Susana; I don't remember how many stands were there when our program started, but in 1954 when we started the accelerated program there were something like four or five, I think. They have quite a few more than that now and they were all built in support of the Ballistic Missile program. All of the stands built at Aerojet in Sacramento, for example, were built for our Ballistic Missile program.

Q. *Will these stands have continued utilization for future development?*

A. Yes. For example, a stand at Edwards which we're just activating now—Stand 1-A—will take a million pounds of thrust. Actually, when you get the safety factors in there you will probably be able to go up to a million and a half pounds. Of course, we don't propose to test anything in this program that has thrust of that magnitude.

Q. *Then, you don't rule out expanded tests in the future, for space flight, for example?*

A. Resources in manpower and facilities and the knowhow in fabrication and techniques that have been established to date and are still on the build-up, are of such a magnitude that the business of space flight is just a matter of whether or not you want to do it and want to spend the money on it. It's no longer a matter of technology or a

The business of space flight . . . a matter of whether or not you want to do it . . .

matter of resources in terms of the facilities and know-how. It's a matter of the funds and the need for doing it, either in terms of military requirement or in terms of national prestige.

Q. *Do you think there is a military requirement for spaceflight?*

A. Certainly, military requirements can be formulated—just one in terms of reconnaissance, that relate to other phenomenon; that relate to matters of the earth's gravitational field, cosmic rays and that sort of thing—these can all be applied to the military. But if you want to be more specific in terms of having space vehicles out there trying to shoot each other down or delivering weapons by space vehicles this is something that I am not able to comprehend in terms of specifics yet.

As we move out into space, I think first it will be to get scientific data. From there, once you get moved out into space, you're going to start identifying specific things that will relate to a specific military mission. I'm sure of this. I think this is an evolutionary thing, and I'd certainly not try at this point to lay out a blueprint as to what this might look like.

Q. *Going back to the $470 million which was spent on facilities, and test stands and what not, does that amount include the scientific study contracts that have been let in the same period?*

A. No, this covers only the actual facilities.

Q. *How much money has industry put in?*

A. When you add up all of the industry facility investments, they total slightly over $100 million. This is industry money out of that total of $470. But here again, like the Martin construction, all of the construction isn't quite complete yet. Neither is the Convair construction program. The Aerojet facility construction is almost complete. So is the North American Rocketdyne facility in terms of their investment.

Q. *What can you say about the progress of the program since you took it over?*

A. Well, actually, I divide the program into four phases and perhaps I should discuss very briefly each one of these phases. The first phase really was a study and organizational phase. After the von Neuman committee made its recommendations to the Air Force that we should accelerate the ICBM program they didn't say take the program that the Air Force had in being then and accelerate it. They said that we should conduct very detailed technical studies and systems analysis to bring about a reoriented program within one year's time. This was to assume maximum benefit from the thermonuclear breakthrough that had occurred. This actually changed the nature of the weapon system in terms of its military characteristics.

First we conducted very exhaustive technical studies and system analysis. At the same time we established this management complex—the administrative actions required to set up the management establishment to clarify procedures, get personnel into place and so forth.

Next we made the major technical decisions that launched the development program that followed. I mean the reorientation of the *Atlas* and a number of other things of a technical nature. That ended phase one. Phase two was relatively short and involved the selection of our industry team. We had to select the total contractor team-guidance contractors, which included both radio-inertial and all-inertial; the computer contractors that went into the radio-inertial guidance contractors; another large liquid rocket development and production agency; the nose cone contractors of which we selected two.

Then we introduced a second approach, a second or alternate ICBM approach which was very, very strongly recommended by the scientific advisory group which kept in being with Dr. von Nueman as chairman. We had frequent meetings with that group.

Q. *Was the von Nueman committee organized strictly to monitor the Ballistic Missiles?*

A. Correct. It was during the second phase then that I considered the selection of the industry team. We of course kept the program going and accelerated both contractors that we had in being. At North American we had to put a great deal more money there during '54 to expand the facilities. We kept Convair more or less at the same level until we made a decision on what changes we wanted in their particular configuration.

When we had completed, for all practical purposes, the selection of our contractor team, the IRBM was not yet in the picture. Next would be what I consider the third phase, which I call the development, fabrication and test phase, which covers, you might say, the real development effort. This of course, had associated with it the vast facility program we've just discussed. Schedules are all paced on getting facilities in being on time, if you want to carry out a crash program. I think, from the standpoint of accomplishment, that getting this facility program accomplished essentially on time was a major accomplishment of our first two years of operation. There have been minor slippages here and there in activating a launch stand here or an engine test facility there, but for practical purposes you could say that we met the scheduled target dates that we laid down for ourselves in this over-all facilities program.

Now that the end of it is in sight it looks as though we will not have any slippages because facilities were not available on time. I don't mean to say that everything has been milk and honey, because it hasn't, and we have not gotten as much testing in some areas as we would like because a facility was a little bit late, but it doesn't appear

I happen to disagree with you . . . a national agency for ballistic missiles won't do . . . would be complicated, I think . . .

that we'll be able to blame facilities for any slippage that might occur in the future.

The fourth phase is the operational phase.

WDD is responsible for all four of these phases. We step out of the operation phase at such time when we have an operation capability. When this operation capability has been established the missile is in fact operationally ready, then it reverts to Strategic Air Command control.

Q. *Are you working closely with SAC?*

A. Yes, but the Command jurisdiction rests with me until such time as it is turned over to SAC, which will be some date in the future. Then we would drop out of the operational side of it entirely and revert back to a normal research and development type organization.

Q. *As far as the long-range missiles are concerned, you're carrying out not only the conventional R & D phase but the training of personnel and the production phase of it and even the operational phase of it before SAC takes over?*

A. Right.

Q. *Isn't that unique in the history of ARDC?*

A. It's unique in the history of the Air Force! I think it's very easy to explain why this is the wise thing to do. We are introducing here a type of weapon which required a rather new operational environment. It isn't another airplane that's going to be operating from a standard aircraft base. The manner in which it is going to be operated is considerably different from the manner in which you operate an airplane. The establishment of the actual facilities—the operational facilities—is in itself a development job which is dictated to a very large extent by the characteristics of the weapon to be employed.

You have got to have very, very close tie-in between the characteristics of the weapon and the characteristics of the facilities from which the weapon is going to operate. You have to marry the two. You can't do it any other way. In order to conserve time, this is the main thing that we are trying to do here. The Air Force felt, that by giving one organization the total responsibility for integrating all of these things it wouldn't be necessary to get everybody's blessing and then call in an umpire if there is a disagreement. I personally feel that in this case because of the uniqueness of this weapon, that this type of an approach is sound.

Q. *Could this concept be employed in any R&D program?*

A. I would not recommend this type of organizational approach, say if we were developing a new airplane like the B-58. It's an advanced jet bomber with better performance characteristics, but you're going to introduce it in exactly the same operational environment as other jet bombers. The manner in which you're going to operate that weapon—the command structure; the communication structure—is going to be very similar to the one you used for the B-47 and the B-52 so you shouldn't depart from standard method for the B-58.

Now, I might comment at this point, I've noticed in the past where your magazine has advanced a national agency of some kind to carry on the development of ballistic missiles. I think everybody is entitled to their own opinion on this. I happen to disagree pretty violently with this philosophy simply because of what I've just been talking about—the necessity for a total program being under the direction of a single agency. If you have a separate national agency somewhere developing the hardware, I'm not saying you couldn't get a very fine agency for the development of the hardware. But the problem of introducing this hardware into a military organization where it becomes a useful weapon, I think, would be complicated to a much greater extent than any benefits that you might derive by having a national agency.

I'd even grant you that maybe you could have one that has a better capability and confidence than we have. But I'd still say that it wouldn't be the right thing to do, unless the differences in confidence were so great that there was a question about our ability to get the job done, as against the other agency's certainty of being able to get the job done.

Q. *How about the scope of testing at the Patrick facility? It seems to be getting sort of crowded with the Army, Navy and Air Force all wanting to schedule tests at the same time. Will this interfere with the testing of the long-range missiles?*

A. Well, I don't know if I can really answer that for security reasons but I think I can say this: the Patrick test facility has never really been called upon to accommodate a large-scale test program. All of the testing down there has been sort of on an individual basis. Procedures that apply to that kind of testing would not be very satisfactory to a large-scale test program such as we envision. We have done a lot of studies with Patrick on the streamlining of procedures to accommodate the larger volume of testing, such things as range safety provisions.

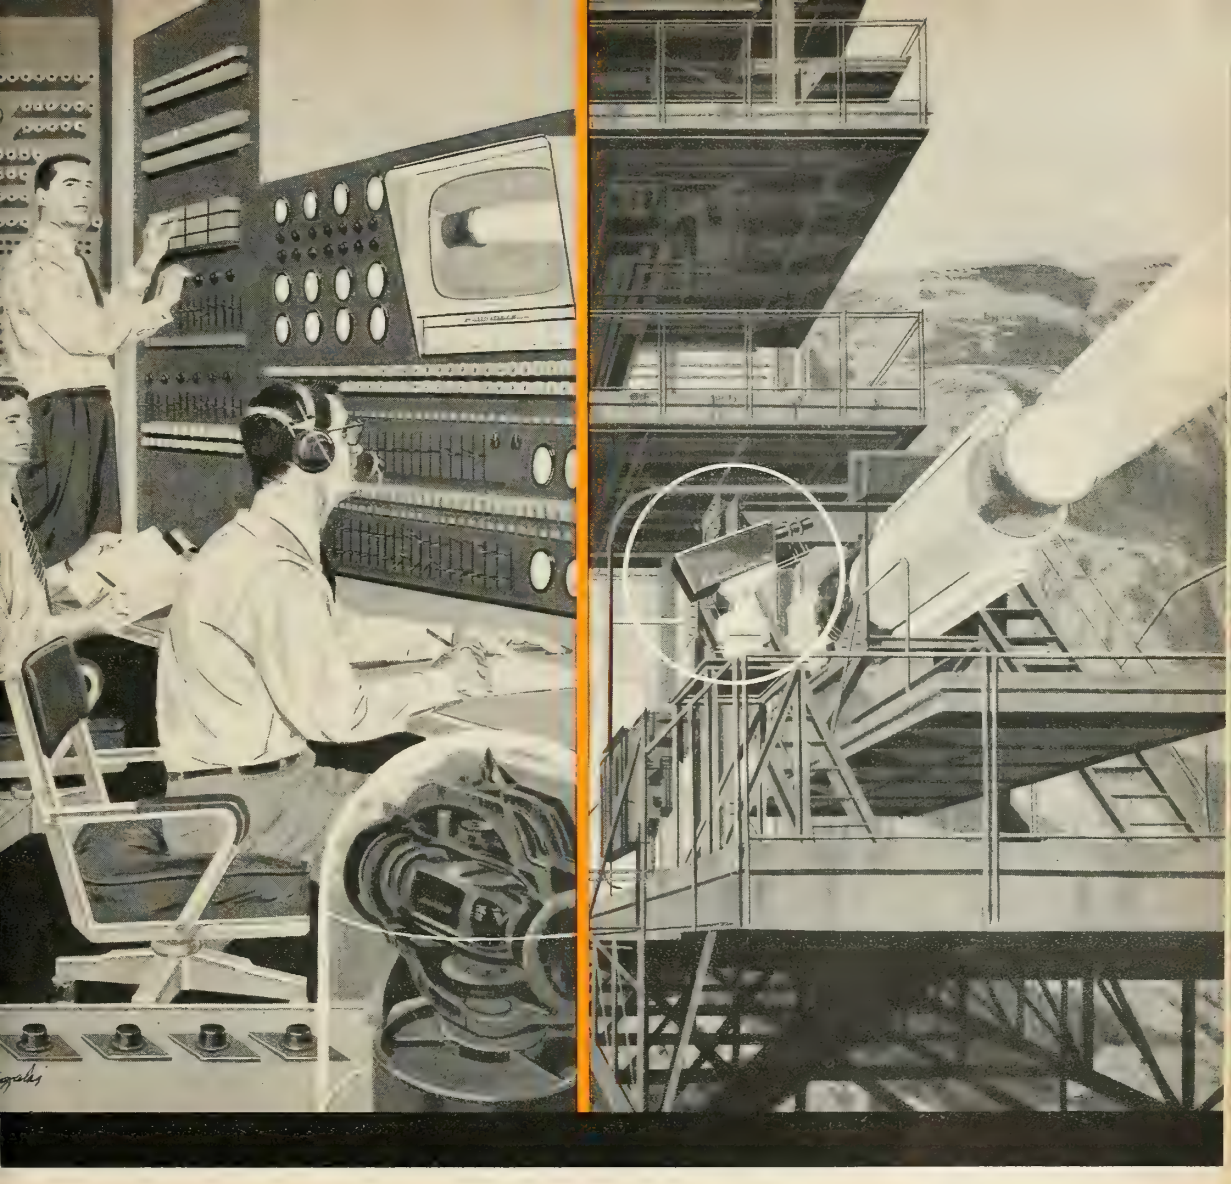
Possibilities of a three-shift operation, in other words, working around the clock on a standard three shift operation instead of calling upon an extra crew that might be required from time to time. We have concluded that there doesn't appear to be any reason why we can't accommodate our test program at Patrick. For the expansion of facilities, from our standpoint, I think we see the end of our major facilities requirement on the horizon. And within a relatively short period of time we will have our facilities, except for minor extensions which are always of course to be expected.

Q. *What does the top national priority that the program has been given actually involve?*

A. I think the best way to put it is that it has generated a streamlining of procedures, primarily within Washington, and it has provided contractors with a priority for materials. It also has resulted in the relative rapidity of decisions from the top level, plus support economy-wise as far as the contractors are concerned in getting their materials, parts and components ahead of any other requirements on the list.

It also, of course, resulted in our getting a very high priority in availability of key people—qualified people. It resulted in our being given the funds required to do the job. I would say the funds plus streamlined procedures for decision making are perhaps the two most important results of the national priority. I think it's fair to say that we have been proceeding at the fastest rate that technology permits.

Q. *Ever since 1954, you mean?*



A. Ever since 1954. During the first year or so of the program the fund requirements were such that it did not require that a national look, you might say, at the funds was necessary and we were able with an Air Force priority to meet the needs of the program at that time. But by the time we had hit the middle of '55 the Air Force no longer could swing it on their own. I mean if we had not gotten a national priority about then we could not have carried on the program at the rate we have.

Q. *Are there any other military projects in existence that involve so much support from industry and science as the ballistic missile program?*

A. No.

Q. *Then, this is the biggest project the Air Force has ever attempted?*

A. To the best of my knowledge that's true if you add up the systems, the *Thor,* the *Titan,* and the *Atlas.* As a total the Air Force Ballistic Missile program is the biggest weapons system project we've attempted. I think that's a fair statement.

seeing a hot one...on Hallamore captive TV

Far too hot, and positively too ear-splitting, for close, on-the-spot observation by human beings...when high thrust propulsion units are fired up for test, Hallamore closed-circuit television takes over the job. Throughout industry, similar Hallamore systems are finding application...wherever the requirement is for remote observation or for fast transmission of visual impressions. Hallamore Electronics designs, develops and manufactures missile ground support and in-flight instrumentation systems, magnetic products, electronic components and audio visual communications systems. Current activity includes contracts for the United States armed forces and prime contractors of the aircraft and ordnance industries.

HALLAMORE ELECTRONICS COMPANY

a division of the SIEGLER CORPORATION

The Ballistic Missile Procurement Problem

. . . as seen by Brigadier General Ben I. Funk

Deputy Director of Ballistic Missiles, AMC
Chief of the Ballistic Missiles Office, WDD

Q. *General Funk, you deal with all of the ballistic missile contractors?*

A. Yes, the contractors are as deeply involved as we in this management effort and in the ballistic missile program—more than any other weapon system program that I know of. They have been around AMC for many, many years, and they have been working on other management problems as well. What we're doing here is asking industry very early in the program to begin gathering what we call "failure rate and consumption data" on the components that are tested. In other words, the WDD people in coordination with R-W set up the tests to be followed by the contractor. The contractor begins getting failure. Normally in an R&D program you're not in such a hurry to know instantly which part failed and how many of these are consumed over a period of time. But here again we need to compress time to meet this priority program. We already have a format that we're implementing which will insure that we do get it—and get it when we need it. Now at Convair, they have more work in process, and they are turning out more work than the rest of the contractors on the *Atlas* because they have a systems integration responsibility in addition to the airframe fabrication. On the basis of the information we get from them we can begin the process of provisioning the spares requirements. Provisioning the spares for not only the missiles themselves, but the ground support equipment. It is extremely important in this program.

Q. *Ground support is one of the things that we'd like to know about. We have an idea that you are now pretty deeply involved in the planning of the actual launching facilities.*

A. Well, we are all involved of course in trying to firm up what ground equipment is going to be required, and what levels of spares are going to be required so that we can budget and buy in time. I'm speaking of the lead time requirements to get all the things into Camp Cooke necessary to make it function as a missile training base. We must be thinking now about what ground support equipment and what spares we're going to need.

When we think of spare parts not only do we have the spare parts problems for the missiles themselves, but ground support equipment has to have spare parts. Let me make an anology particularly applicable in this weapon system. With a gun, you of course think of the gun and the bullet. Well, we have a lot of guidance equipment and a lot of support equipment must stand on the ground. Your missile's the bullet, and your gun costs a lot of money, and this is where the uniqueness comes into this program; whereas most ground support equipment percentage-wise, would run, anywhere up to 35% depending upon which weapons system you are talking about.

In this program it may run as high as 50% of the total cost for ground support equipment alone. So you can see the importance of making certain that we are selecting the right kind of ground support equipment and that we're not duplicating anything that is already in the inventory.

Q. *How do you go about implementing your long-range planning objectives?*

A. We visualize the use of electronic data processing means to actually manage all of the assets to support a weapon system. By that I mean we have our common Air Force items; then we have the design procurement items which the contractors themselves are responsible for; certain government furnished equipment and certain contractor furnished equipment. We would use the large computers that industry is now turning out to compute and determine levels that would be required, say at a support base, launch complex or at a contractor's facility. Now, at least initially, we feel that in order to buy time (and this is a phrase we often use here too) we need to have the contractors provide us with the depot level of supply and maintenance for their procurement items. Under our AMC depot system, usually the depots themselves do the whole depot level job to support the weapon system in the field.

In this program we may run as high as 50% for ground equipment . . . we're taking a calculated risk . . . we may make some changes . . .

Here we would bring in the contractors. We've got to contract with him to not only build this weapon, but to support this weapon. We are actually in the initial stages of working this out with the contractors now. This is during the initial operational capability phase that I'm talking about now, and my weapon system manager responsibility would implement that type of a logistics plan.

Q. *How does your job differ from a normal AMC job? Is it normal for AMC to get into the act of producing weapons at this early date, and is it an advantage?*

A. It is not usual for AMC to get into the act of producing weapons at such an early date. Here again though, if you're going to buy this time that we keep talking about, there's no other way to do it than to accomplish the R&D, and production-operational phases on a parallel basis. Obviously, we're taking a calculated risk that maybe we're going to make some major changes. We don't think we will. We think that the necessary changes will be minor. In effect, this is not "business as usual"; this is pioneering. We have to deviate from the old established hand-driven methods, and we do this whenever we feel it buys us time.

Q. *Does your office get involved in choosing personnel for the project, or do you leave that to the contractors?*

A. We provide a surveillance function with the contractor to be sure that he is getting proper quality and quantity of manpower to do the job. If we're dissatisfied with the number of engineers and technicians that he has—for example, if he is late on his engineering work order releases; if he's out of station on his production line based on lack of engineering effort, we're to take action and tell the contractor he needs more qualified engineers or whatever. He gives us a forecast of his manpower buildup by category of manpower, manufacturing, engineering and so forth, and we monitor this very carefully and look at it in a monthly management meeting we have here.

Q. *How do you go about determining contractor specifications on something you've never built?*

A. Well, there are no specifications, in the main, in this program because we're doing something brand new—new fabrication techniques, new types of weapons. So we have to deviate from the normal acceptance procedures for Air Force materiel. Where you'd normally inspect to a certain set of specifications, we don't have them so we have to use our best judgment here as to whether we do or do not accept something.

Q. *What about problems you don't anticipate, such as the contingency factor?*

A. We're realists, let's put it that way. We have had enough experience that we can generally anticipate the areas where we're not going to have difficulty and where major testing is being accomplished. We do a lot of testing on the ground to insure a reasonable degree of certainty that we won't have any delays due to a particular new fabrication technique or new metal or something like that. The degree of reliability required in this program is unique. It's higher than any other weapon system program simply because you launch unmanned missiles, whereas when you launch a bomber if it doesn't work, you just fly back home.

When you launch a missile it's gone. In this business you must build in a very high degree of reliability, and this reliability is not only in the weapon system itself, it's in the systems which stay on the ground and in the ground support equipment. Reliability is here again unique, and it's highly important.

Q. *What about storage? Can you store the missiles for four or five years and then take them out and make them work?*

A. Well, the missiles won't be around for four or five years. Obviously you must have a degree of readiness at all times. I'm not going to go into the degree of readiness because it is classified. But it does require the rotation of operational inventories for example.

Q. *Well, isn't it safe to assume that when you reach the production stage, you will have a certain production output of these missiles at all times, because you will obviously have to launch some of them for training purposes?*

A. Definitely. We're not going to build just so many and then quit!

Q. *You're going to shoot the missiles as part of your crew training program?*

A. Of course, you're absolutely right. So provided a contractor performs well under the contract terms it is reasonable that he would still continue to be in business for some time to come. You not only have this problem of production in the missiles, but here again the ground support equipment and the spares must be programmed for. It's not a one shot deal in any sense of the word, but a continuing program. It's the one thing that I think a lot of people misunderstand.

There is a tremendous amount of planning that has to go into this weapons system to make it a useable programmed weapons system—not only is it a program for the procurement, production, logistics, logistical support, training, base selection, base building, you're also building the installations, you're building communications systems; you're building electronic data processing systems; you're building contractor capability to do supply and maintenance of the weapons, as well as getting an Air Force capability to the degree that it can supplement the manned bomber force.

This is not business as usual, this is pioneering . . . we're not going to build just so many and then quit!

The Ballistic Missile Management Problem

. . . as seen by Dr. Simon Ramo

Vice President, Ramo Wooldridge Corp.

Q. *Dr. Ramo, how are the financial aspects of the ballistic missile program handled?*

A. R-W does not have any connection with monetary phases of the program. No money passes through R-W. We do laboratory work, we simulate the whole system, we do regular dynamic analysis, we do certain kinds of laboratory explorations on any fundamental point that is basic to a decision that has to be made. We supervise the final system tests. We decentralize to the airframe manufacturer what you might call the physical integration and system test operation. We do not attempt for example, to design hardware details.

Q. *What is the size of your staff?*

A. Well, I can't give you the precise number, which is classified, but there are some hundreds of engineers and scientists. These experts are assisted by certain non-technical, administrative, clerical and other help. Our principal group is composed of some forty people, average age 40, who have 15 to 20 years experience, and who are graduates of programs of this general kind. You'll find that many of our key people have associated with other successful complex programs, extending from World War II to missiles of the last ten years to other weapon systems, including Manhattan project assignments.

Q. *Will you expand the GMRD as the program goes along?*

A. Well, the program has not yet hit its peak personnel requirements but it is very close to it. Obviously, we do not anticipate any need for expanding indefinitely. Nor do we plan to ever go into production in this general area of ballistic missiles. This is of course a key point. We have felt it's rather important in taking on the systems engineering work for this project, to be sure that every one of our decisions are based on the most objective thinking possible. Thus we have no production contract and engage in no production in connection with the ICBM program.

Q. *How about the need for more missile engineers for this particular program, say, during the next 15 and 20 years?*

A. Well, of course, what has to be decided is what rate is essential. The number of engineers and scientists that we have will partially determine how fast we go in this highly technical society of ours. Most of the time in connection with most of the things that are happening today, I do not believe that there is a shortage of engineers and scientists. But, rather it's a problem of how we utilize the available scientific personnel.

Q. *We have noted that the locations of the contractors engaged in the Air Force Ballistic Missile Program are spread over the whole country. Does the dispersal aspect of National Defense play any role in this?*

A. It did to some extent during initial stages of the program. It is not easy to talk inquantitative terms as to the decisive step. For example, North American was the major developer and supplier of large rocket engines. And Aerojet was another. We notice that both of those are California companies. And we notice that both of those have had a very great deal of expansion from the standpoint of facilities. We also notice some things, however, in the Mid-West in support of these companies. Convair and Douglas as two airplane companies, are both located in Los Angeles with expansions of their programs and with large systems test support in their areas; such as San Diego and at Edwards Air Force Base. We also notice that while Martin is located in Baltimore, Maryland, it has a division in Denver working on this project. So, you see there is a certain amount of dispersal.

Q. *The Martin Division in Denver was actually set up for this program?*

A. The Division in Denver was set up after they came into this program.

Q. *So it might be safe to assume this move was dictated more by the ICBM program than by the dispersal aspect?*

The number of engineers . . . will partially determine how fast we go in this highly technical society of ours . . .

"ARCTIC STARS," latest in a series of paintings by Simpson-Middleman, painters of the meanings of science. They describe this interpretation as "an expression of entropy in the cosmos. Starlight, clear and cold, contrasts with the warm color of autumn leaves. Behind both, the undulating field of the celestial wall." Painting courtesy of John Heller Gallery Inc.

Explore frontiers of the future at Boeing

There's adventure for you at Boeing, where scientists and engineers make exciting discoveries along frontiers where the future begins. There's stimulation, too, working with men whose creative genius has ushered in new eras of flight.

And challenge—developing new techniques, new materials, new processes and equipment. Boeing engineers and scientists invite you to join them in assignments that give you creative scope, personal satisfaction, and added professional stature.

We welcome engineers of *all* types, scientists and mathematicians. You'll like the adventuring spirit here, and the unexcelled facilities. You'll find "you belong . . . at Boeing."

BOEING

Drop a note now to John C. Sanders, Engineering Personnel Administrator, Boeing Airplane Company, Dept. A-62, Seattle 24, Washington

A. Well, at any rate, I think this is a conjecture that you yourself have to make. Let me point this out, certainly it is true that companies have been expanding and seeking other locations. In our case, the Denver plant of the Ramo-Wooldridge Corp. is intended for larger scale production than we will do here in Los Angeles. A major reason for our going to Denver was the dispersal policy. However, there are some advantages in our locating ourselves partially out of Los Angeles in any case. Thus we also have offices in Dayton, Washington, D.C., Boston and Cocoa Beach, Florida.

Q. *Did you say R-W was a production facility?*

A. Yes, this applies to our five other divisions but not to the GMRD, which works only on the Ballistic Missile Program.

Q. *What do your other divisions do?*

A. Well, to make it very short and simple, the Ramo-Wooldridge Corporation was set up with a number of divisions emphasizing electronics work; not only the systems engineering aspects of electronics projects but the actual development and production of equipment right through to spares and maintenance. We were engaged in these activities when the Air Force asked us to take on the ICBM systems engineering and technical direction assignment. To do this job we set up our Guided Missile Research Division solely devoted to ICBM. The Guided Missile Research Division is only concerned with systems engineering and technical direction for the Air Force's Ballistic Missile Program. It does not do any production nor will that division do any production on follow-on jobs.

Q. *Does the R-W Denver plant have anything to do with the fact that Martin also has a plant there which is doing ICBM work?*

A. There is no connection whatsoever. As a matter of fact, we had acquired the Denver land before Martin was in the ICBM program.

Q. *But Dr. Ramo, hasn't R-W been involved in aiding the Air Force in selecting companies for the Ballistic Missile Program?*

A. We are involved indirectly in a sense that we propose the R & D plan which tends to define the nature of the needed contractors. The Air Force alone chooses a candidate list. We brief those candidates during the short competition period which is always held by the Air Force. In general, all the contractors have been chosen by competition and by the Air Force. We do evaluations on both their oral presentations and on their written presentations, but only from the technical standpoint, and finally we withdraw and are not part of the final deciding team.

Q. *Do you provide some of the contractors with assistance from your expert engineers and scientists?*

A. Yes, the reason this happens is this: Though we try very hard to decentralize the detail, design and development, things will arise in which the interaction between one part and other parts is the key point of importance and we are in a position to see it most rapidly. It is natural that we try to help when we can. But we don't attempt to, and it would be absurd to imagine that we could try to fix it so that whatever every contractor can do, we also have the capability of doing.

Q. *Do the various contractors have representatives here in Los Angeles?*

A. Some of them do.

Q. *On a permanent basis?*

A. Some of them do and some of them do not. But you must remember that there is a tremendous amount of interaction to technical meetings so if you look at any given time you will find WDD/RW buildings full of contractors' representatives. This makes for excellent inter-communication between RW and all major contractors. Basically, we were a little surprised to see how well it worked out ourselves.

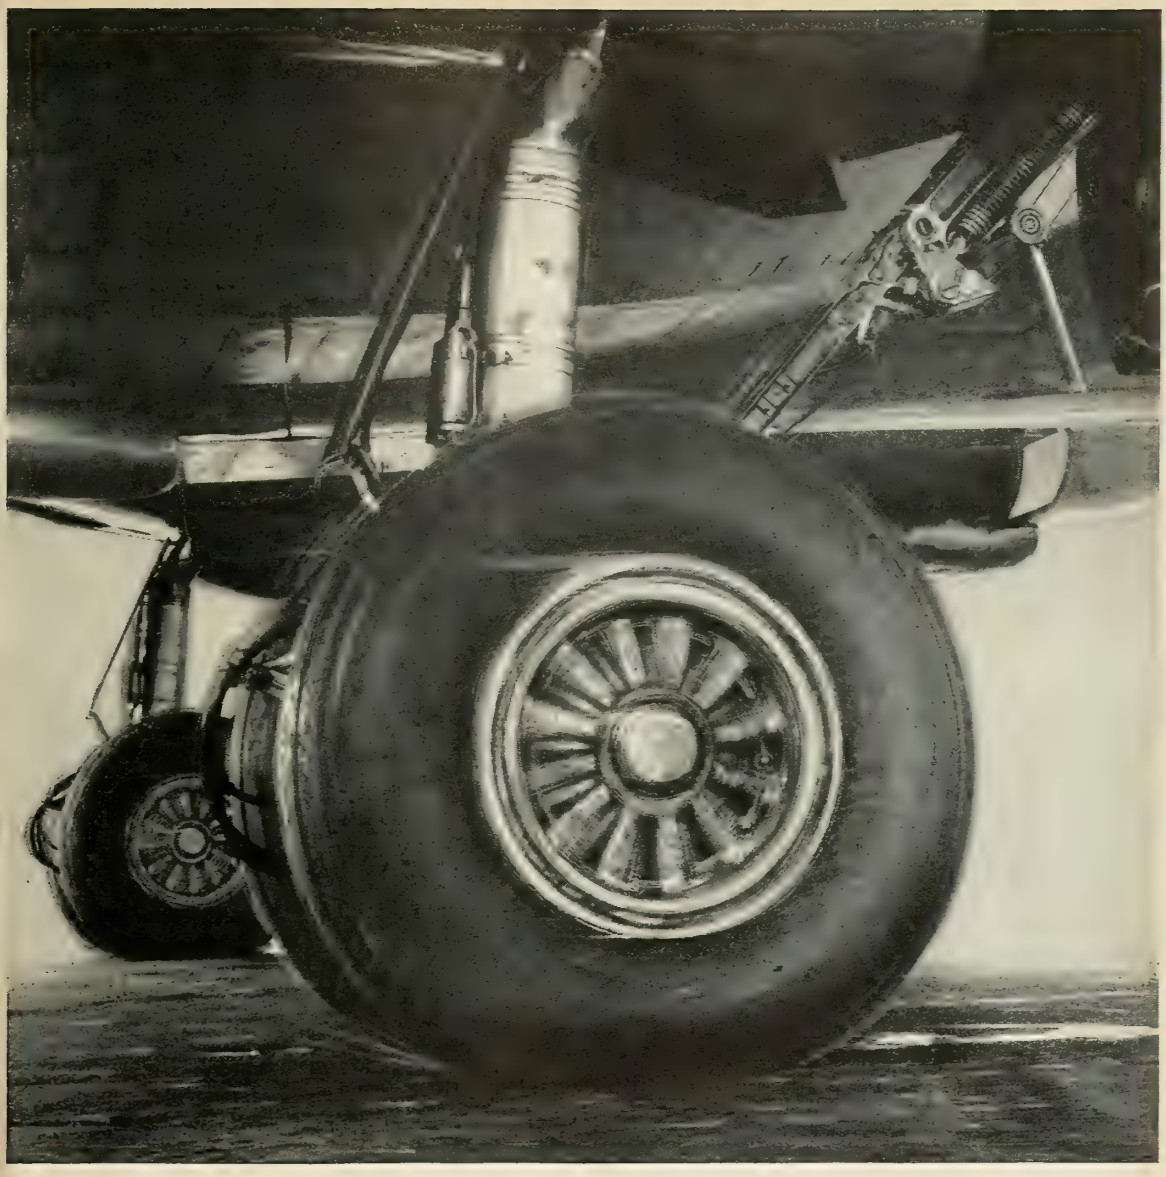
Q. *Is there a good deal of travel involved?*

A. Yes, there is a great deal of travel, but this is unavoidable. There is an attempt to arrange meetings and other communications for efficiency. We have perhaps made advances in communications on large projects. It is a problem—always will be when things have to be large and spread out. We have the best organizations in the country and their top technical management are good at communications. These people are developing unusual skill at this; the teamwork is almost exciting to watch.

Q. *Do you anticipate that in the future you might go to closed circuit television conferences?*

A. Actually the communication of words and numbers is much more important than the communication on a visual channel in our work. So that while I have no doubt that years from today, in setting up a major project that is widespread and of an urgent crash nature, one would probably employ television nationally to an elaborate extent. I don't think we are going to take time off to inject it into our system now.

Q. *Do you consider this responsibility to be a great personal challenge?*



A. You see I feel that we are part of a large team getting a big job done. I would guess in other words that each man in his own way, here and with the various contractors and in the military; each one of them finds what he has to do on the job is a challenge. And each one of them is quite cognizant of the fact that he needs to get his job done or it can be a significant blow to the project.★

...I feel we are part of a large team getting a big job done...get the job done or it can be a very significant blow to the project...

Lightweight! But magnesium can really take punishment

Magnesium is the world's lightest structural metal. It weighs only 23% as much as steel, 20% as much as yellow brass and 65% as much as aluminum. But magnesium is strong, too. How strong? Look at a few of its uses in the aircraft industry, for example:

The magnesium wheel in the picture above has to be light, but it also has to withstand tremendous shock when the plane touches down. In another application, the entire weight of a two-ton helicopter is suspended from a magnesium rotor. In large cargo planes magnesium floor members support heavy weights in flight.

Magnesium was selected because it has the necessary lightness, strength, rigidity, durability and other desirable properties. It's the *combination* of light weight and strength that makes magnesium the choice for countless applications throughout industry.

What do these facts mean in terms of your products, parts or equipment? They mean that magnesium can do an equal or better structural job at a substantial savings in weight. For more information, contact the nearest Dow sales office or write to us. THE DOW CHEMICAL COMPANY, Midland, Michigan, Magnesium Department MA 1401G.

YOU CAN DEPEND ON DOW

Astrionics

By Henry P. Steier

SAN FRANCISCO—Fastest growing area for the electronics industry lays within a 100 mile radius of this hilly city. Single level, "California style" buildings for small electronics firms, and for Eastern firms opening branches in the area are being put up at a great rate for leasing. Together with the leased buildings many firms also lease the electronics test gear and machine tools for R&D and manufacturing.

Old established firms in the area like the Hewlett-Packard Co., Eitel-McCullough and Ampex Corp. which are noted for the high quality and flexibility of their manufacturing operations are expanding rapidly. Admirably suited to meet demands on the electronic industry, many firms are planning complete moves of entire facilities to new and bigger buildings or additions to existing ones.

Ampex Instrumentation Division business has jumped from $12 million in fiscal 1955 to $19½ in 1956. Big percentage of tape recorder instrumentation business is in the missile field. Tape systems for aircraft flight evaluation and engine tests have been growing in use, and for missile telemetry uses promises to be even greater.

Operating without any competition in its specific field the company has doubled its personnel in the past year. One reason is new use of Ampex tape systems in hypersonic missiles. Range and radio transmission problems in ICBM test vehicles are being met by recording the data on vehicle-carried tape recorders. Ampex officials will not say how tape is recovered or *if it is.*

One theory is that data is played back during slowest moving part of the missile re-entry flight period. In any event, the firm's laboratories are swarming with ICBM "brass" these days.

•

IRE NATIONAL CONVENTION, 1957—The big show and convention drew 50,000 registrants this year. With 800 exhibitors showing their wares in the New York Coliseum for the first time everyone agreed it was the most pleasant, informative and comfortable show ever.

Everything was new, from the booth displays to the people manning them. Especially noticed was the high technical competence of company personnel who answered questions about the companies' products. Complaints, mounting over past years, that booth personnel were apparently only there to guard the booths were not heard.

Something else new was a complete morning and afternoon session on astrionics. Recognizing the new problems being faced in telemetry and remote control for long range missiles, and space ships a symposium on this subject was a feature of the Convention. The other session was a symposium on techniques for data acquisition and handling in the missile field which emphasized that newest hope for rapid missile data handling-digital systems.

Latest look in booth displays was RCA's calm-looking reflection pool around one corner of the display. The pool soon turned into a "wishing well." Passing engineers soon had the bottom of the pool covered with shiny copper pennies tossed in for who knows why. One joker, however, had tossed in a General Electric Co. medallion which looked like a silver dollar at first glance.

To the ENGINEER of high ability

Through the efforts of engineers The Garrett Corporation has become a leader in many outstanding aircraft component and system fields.

Among them are:

air-conditioning

pressurization

heat transfer

pneumatic valves and controls

electronic computers and controls

turbomachinery

The Garrett Corporation is also applying this engineering skill to the vitally important missile system fields, and has made important advances in prime engine development and in design of turbochargers and other industrial products.

Our engineers work on the very frontiers of present day scientific knowledge. We need your creative talents and offer you the opportunity to progress by making full use of your scientific ability. Positions are now open for aerodynamicists ... mechanical engineers ... mathematicians ... specialists in engineering mechanics ... electrical engineers ... electronics engineers. For further information regarding opportunities in the Los Angeles, Phoenix and New York areas, write today, including a resumé of your education and experience. Address Mr. G. D. Bradley

AiResearch servo-controller for a pilotless guidance system

Simple servo-amplifier...actuator system achieves maximum speed of response with high stability

Because most missiles and drones are self-destructive, it is important that the components in their guidance systems be both highly accurate and dependable and be producible in quantity at low cost. The AiResearch servo-controller meets the above requirements.

It operates as follows: an AiResearch servo-amplifier weighing less than .7 of a pound amplifies electric signals from an inertial guidance source and converts them to command signals. These in turn are transmitted to an AiResearch electrically-powered light weight linear actuator which adjusts control surfaces of missile or drone to maintain a predetermined course.

The servo-controller can operate from either a DC or AC power supply. It can also be designed to take signals from celestial, telemetering or pre-programming sources to maintain or readjust the course of its pilotless air vehicle. It is another example of the AiResearch Manufacturing Division's capability in the missile field.

Inquiries are invited regarding missile components and sub-systems relating to air data, heat transfer, electro-mechanical, auxiliary power, valves, controls, and instruments.

Outstanding opportunities for qualified engineers.

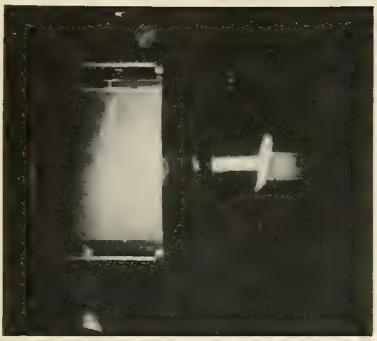
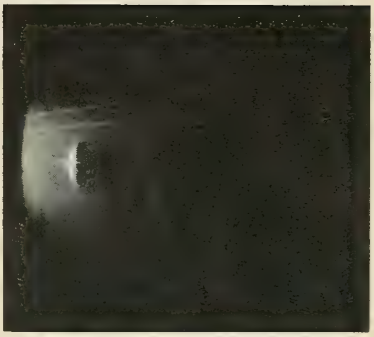
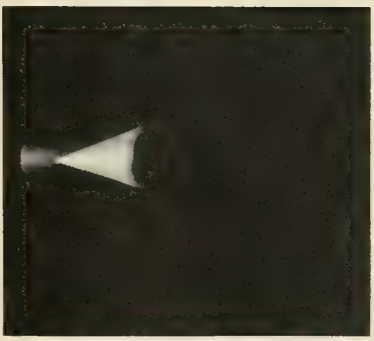
To Put the Sun to Shad

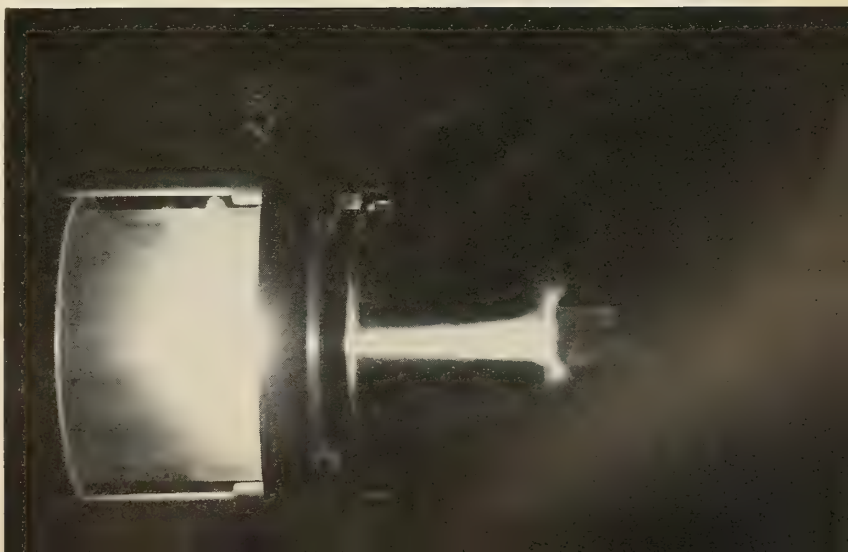


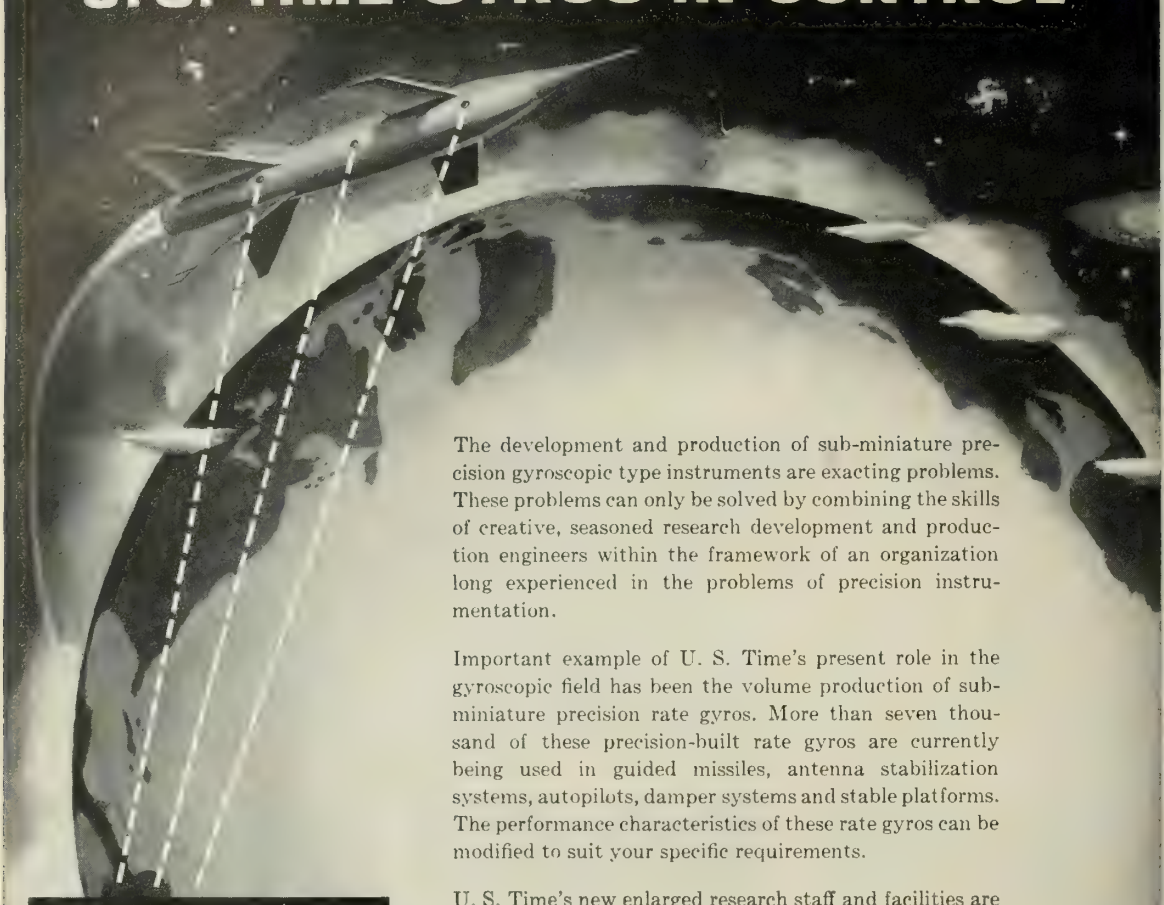
The melting, spalling test cone above provides a vivid demonstration of the problem of high-speed reentry into the earth's atmosphere. Operating in vacuum chamber this water stabilized arc produces a flow of atomic vapor with temperatures exceeding those of the sun's surface. Developed jointly by General Electric Company's Missiles and Ordnance Systems Department and the University of Chicago, this unit using a one-quarter-inch graphite electrode is at MOSD's Philadelphia Aerophysics Laboratory. Below, a medium drag-to-weight ratio nose cone is ready for test. Note equipment's small size, simplicity.



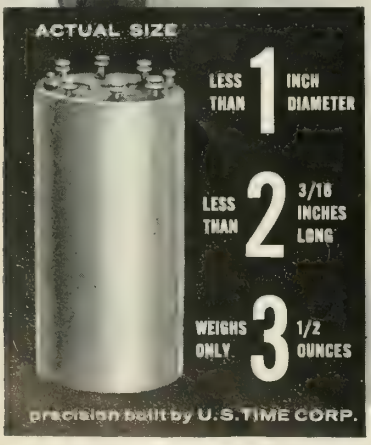


o the right are a variety of test shapes and aterials under test. With the exception of vo in the block of four (pointed cone and oolie hat) all of the runs on this page are air. Notice the tendency to burn as well as elt, sublime and spall. This unit is powered y four electric welding arc generators shown the picture immediately below. Larger units ow being built will produce temperatures of 0,000°K, and will require 10,000 volts d.c.





ne photograph at the bottom right of this age shows MOSD's water stabilized arc, or lasma jet as it's sometimes called, at about alf its actual size. A major advantage of is equipment is that testing conditions can e maintained for several minutes consecuvely. Heating rates from 2000 to 6000 BTU er square foot per second have been atained with much higher rates in prospect. or further information see Aerophysics, this sue, and the news section of m/r for March.



U. S. TIME GYROS IN CONTROL

The development and production of sub-miniature precision gyroscopic type instruments are exacting problems. These problems can only be solved by combining the skills of creative, seasoned research development and production engineers within the framework of an organization long experienced in the problems of precision instrumentation.

Important example of U. S. Time's present role in the gyroscopic field has been the volume production of sub-miniature precision rate gyros. More than seven thousand of these precision-built rate gyros are currently being used in guided missiles, antenna stabilization systems, autopilots, damper systems and stable platforms. The performance characteristics of these rate gyros can be modified to suit your specific requirements.

U. S. Time's new enlarged research staff and facilities are engaged in research, design and development of miniature precision instruments—instruments to withstand and perform under the severe environment of supersonic aircraft and missile flight.

We invite inquiries in the following fields of precision instrumentation:

STABLE PLATFORMS • FLOATED INTEGRATING GYROS • ACCELEROMETERS • RATE GYROS • TWO AXIS GYROS • DAMPER SYSTEMS • INERTIAL INSTRUMENTATION • GUIDANCE SUB-SYSTEMS

Aerophysics

By Seabrook Hull

A new science—heliodynamics—may result from tools now being developed for studying ICBM heat transfer rates.

Within 12 months so-called plasma jets will be in operation capable of producing temperatures on the order of 50,000°K and stream flow velocities of Mach 15 and up. Inherent in these devices will be heat transfer rates in the range of 10,000 BTU per square foot per second and an ionized gaseous environment "seen" heretofore only through celestial spectrographic analysis. The equivalent black body surface temperature of the sun is about 6,000°K, 50,000°K would be found 600 miles below the sun's surface.

ICBM reentry ballpark figures are 6,500°K and 1,000-to-3,000 BTU, depending on nose cone design and construction. On the same dependence, reentry speeds range up and down from Mach 20.

Both Giannini Research Laboratory and GE's Missiles and Ordnance Systems Department, in cooperation with the University of Chicago have recently announced successful plasma jets. Using relatively small electrodes and "moderate" power sources, temperatures over 14,000°K and heating rates of 6,000 BTU have been achieved. Flow rates have ranged from subsonic to moderately supersonic. In both cases, arcs have been water stabilized.

MOSD, however, plans to complete construction by year's end of a 10,000 Kw arc using a three-inch electrode. Plans are also under way to use liquid air stabilization. Extreme temperatures and flow rates are anticipated. In addition liquid air, when vaporized and ionized by the arc into a plasma, will more closely duplicate actual reentry environment. The 10-to-15% carbon vapor concentration that results from electrode disintegration is not considered to be particularly troublesome.

The plasma jet is still a little-known device. One problem is how to reduce temperature without cutting Mach No. Others involve selection of components to withstand temperatures for protracted running times—several minutes. In one case a graphite electrode drooped; the brass fitting dripped away. These problems, however, are not considered troublesome since peak temperatures occur at the nozzle or beyond.

Similarly, plasma jet potentials have only been suggested. Consisting of charged particles they can be affected by magnetic and electric fields. A study plan is under way to appraise it as the driver section of a hypersonic wind tunnel. Its real benefit, however, may lay in its yet-to-be-developed usefulness in the basic study of matter. In part it duplicates conditions within the sun, results in material states, such as $C_3 7$, never before found on earth. As a basic research tool its redevelopment at this time amounts to a major technological break-through.

•

For aerodynamic study of ICBM reentry problems, GE-MOSD has constructed an expansion throat at the end of the six-inch shock tube at its Philadelphia Aerophysics Laboratory. This device will permit study and optical observation under what amounts to full-scale conditions—with large enough models that the scale effect of the atmosphere no longer need be taken into account.

A check of the state of the reentry nose cone art reveals: (a) it's still highly classified; (b) research may be producing as much new confusion as new answers and (c) though there's still a lot to be desired, it won't be the nose cone that holds up production of operational ballistic missiles. One problem is that some materials that show promise in one test device, pack in in another. Thus the usefulness of plastics, for example, still remains somewhat in doubt. Another problem appears to be how to prevent the reentering warhead from tumbling. Meanwhile, current designs still heavily favor the high drag-to-weight ratio concept.

limitless...

Poly-Scientific's newly perfected manufacturing processes permit limitless variation in design every part custom made to your individual requirements.

Poly-Scientific is synonymous with versatility, precision, and performance. Every slip ring, commutator and brush assembly made by Poly-Scientific is the ultimate in quality.

The use of epoxy resins allows greater miniaturization without sacrifice of strength. Our perfected techniques permit the use of any of the noble metals and alloys, making possible the selection of the optimum material with the proper hardness for each specific application.

Dependable, long-life performance... minimum generated noise... freedom from tarnish... dimensional accuracy and stability . . . all of these are automatic when you specify Poly-Scientific. And best of all, prices are competitive.

miniaturized slip ring assemblies
brush assemblies
commutators
to fit any requirement

A real achievement in sub-miniaturization: thirty-two 0.140" diameter rings in less than one inch of length, with no sacrifice of electrical or mechanical characteristics! Rugged and accurate stainless steel flange and center rod insure perfect alignment. Solid coin gold rings of 140 Brinnel hardness are finished to a high polish. Also note color coded teflon insulated leads.

This extremely accurate commutator, used to generate a critical impulsing sequence, is fabricated with coin gold segments common to the end contact and P-30 epoxy resin, the combination of which guarantees uniform wear and long life.

Career News for Engineers!

Flight Tests are under way on one of America's most important defense projects:

The Navaho Strategic Missile

Artwork based on Official U S Navy Photograph

The results are secret—but this much can be told. A test vehicle designated the X-10 has gathered new aerodynamic and electronic information which will help to speed progress on the SM-64 Intercontinental Strategic Guided Missile.

The opportunity—and the privilege—to implement this revolutionary data is yours.

Twenty-eight-year-old Army vet **WILLIAM T. SCHLEICH** was graduated from Georgia Tech in 1952 with a BSAE. He joined North American as a junior engineer the same year. Seven months later Bill was promoted to aerodynamics engineer for the Navaho missile program. He was appointed Supervisor, Stability and Control Unit in October of last year. With the help of North American's Educational Refund Plan, he received his MSAE from USC. Bill and his wife are hi-fi enthusiasts and have a sound system built into their Whittier, California home.

If you accept this challenge you'll be solving tomorrow's problems—today. Here facts are collected fresh daily. If yesterday's yield proves inconclusive you'll approach the problem from a new direction. You'll travel new paths and develop new inventiveness. And you'll be guided to each breakthrough by the world's best-informed missile authorities—your own associates.

One example of the new hardware evolving from this creative engineering effort is a fully transistorized electronic commutator. This instrument increases the information-relaying capabilities of the missile's telemetering system by commutating 27 outputs at speeds of approximately 100 cycles per second. It was developed by the Flight Test Instrumentation Group.

North American's Missile Development Division is a major center of missile activity—and a pioneer in the field. As far back as 1948 its first test instrument vehicle was fired from a launching platform. Today North American has complete weapons system responsibility for the Navaho—and its test program is being conducted at the Air Force's long-range missile proving ground which stretches more than 5000 miles across the Caribbean and far into the South Atlantic.

LYLE C. BJORN has lived aviation all of his life. As a high school boy he built a glider modeled after the Wright Bros.' first flying machine—flew it from ski jumps near his Utah home. He studied engineering at Utah State and earned his BSME degree from the U of Wyoming. Lyle joined North American in 1951 and is now Group Leader, Field Test Operations at the Missile Test Facility, Patrick Air Force Base, Florida. He lives with his wife and three children near Cape Canaveral where he is an active leader in Cub Scouts.

If this sounds like the kind of career-opportunity you've been looking for—write us today. We promise you a working climate that stimulates personal growth and rewards it with responsibility, professional recognition and material benefits limited only by your own ability. Further, you can continue to grow academically with the aid of our Educational Refund Plan—and some of the nation's finest universities are nearby.

Let us know what kind of creative engineering interests you. (Please include highlights of your education and experience).

CONTACT: Mr. R. L. Cunningham, Engineering Personnel Manager, Dept. 495-MAR-42
Missile Development Division, 12214 Lakewood Blvd., Downey, California.

NORTH AMERICAN AVIATION, INC.

A Boom Town Bursts Its Seams

. . . nothing adequate but bars and jobs in COCOA

by Don MacDonald

WHEN THE DEFENSE Department in 1947 chose to reactivate a dormant Naval air station now known as Patrick Air Force Base for potential use as a guided missile test center, it displayed excellent geographical logic. There was no better spot on Florida's East coast from which to pepper the Atlantic with untried rockets sure to be occasionally erratic.

However, as was true so often during World War II, military practicality overshadowed the inevitable need for housing thousands of scientists, engineers, technicians, and their families recruited for the program. The result, 10 years later, is Alamogordo number two—a bleak little boom city called Cocoa.

The initiative of its grocer founder, a man named Willard, can be judged from the fact that when postal authorities in 1822 rejected his first choice of names—Indian River City—as too long, he glanced around his shop, spotted a case of newly arrived beverage, and so the town was born.

Until the advent of Patrick, Mr. Willard's inertia carried through to his descendants. Even judged by Florida standards where a potential alligator farm can be sold for $500 an acre, Cocoa could not claim its fair share of tourists or retired folk, much less entrepreneurs who could contribute more solidly to the area's economy. Major private industry was and still is citrus farming, although breeding Brahman cattle—which thrive where other types fail—is fast becoming a local specialty.

None of this is Cocoa's fault as such. The scenery is like any other part of East coast Florida—flat, palmetto-studded sand, moss-hung live oak, and an occasional palm. The beach is one of the best for swimming. Fishing, especially for salt water trout, is tops. Being roughly at Florida's coastal midpoint, Cocoa's climate is never too hot, and seldom chilly. January averages a comfortable 62 while August is shirt-sleeve moderate at 82 degrees.

As all m/r readers know, jobs go begging in Cocoa. Any engineer who can define ICBM just about has his choice of the Air Force or the numerous aircraft and components manufacturers of the area. Pay scales for scientists, engineers, and technicians are well above normal Florida levels in non-critical industries, just as they are for the trades. Permanent residents within a 100-mile radius complain that no one will fix their leaky faucets nowadays—all the plumbers went to Cocoa.

Anyone accepting a Cocoa job should insist on per diem payments until he settles his family. Typical arrangement now being offered by major employers includes seven cents per car mile from point of hiring plus $7.50 per travel day (350 miles) for the employee, $5.00 for his wife, and $3.50 for each child. Upon arrival, the daily payments are continued up to a usual maximum of 30 days, during which period the employee is supposed to be hunting for permanent housing.

Local motels are well aware of this scale. One newcomer interviewed reported paying $93 a week for a one-bedroom and kitchenette unit to temporarily put a clean but certainly not AAA rated roof over the heads of his small family. Another older hand stated that if he had it to do over again, he would insist on an expense account covering the cost of feeding and sheltering his family over and above a deductible $200 per month. "This," he snapped, "should continue indefinitely until a family finds acceptable perma-

Waterfront development is one of many planned by Gus C. Edwards, local real estate mogul. This picture, taken in February 1957, does not indicate much progress towards solving Greater Cocoa's housing problem.

Enlightened solution by Convair benefits only its own employees, will ultimately give 350 families waterfront homes on easy payments.

New Central Brevard National Bank, locally built and capitalized, is one of few signs of Cocoa's sense of industrial responsibility.

Whimsical sign marks offices of the Greater Cocoa Chamber of Commerce. Newcomers would like less whimsy and more action.

nent housing at a cost bearing some logical relationship to its income."

"We've been here nearly a year," he continued, "and look at this place I had to rush into buying!" He pointed to his nondescript three-bedroom home standing in a row of dozens like it and went on: "It isn't even CBS [stands for 'cement block stuccoed,' a kind of construction unpopular with Florida's voracious termites], the lumber is green, and nothing fits. It cost me twice the $7,000 I could duplicate it for in Oklahoma City."

The most unfortunate Cocoites are those who must rent. If anything is available, which is not usually the case, a minimum rental for the home described above would be $150 per month without utilities or furniture.

Surprisingly, some of the worst gougers can be found in the ranks of fellow employees. Those who had been through the experience of Alamogordo and the like saved their money, came to Cocoa, purchased at least a duplex and in some cases a whole block of homes, and now make more money as spare time realtors than at rocketry.

The Daytona Beach News Journal, 80 miles up the coast, recently featured a series of interviews between one of its newshens and would-be Cocoa residents temporarily lodged in 36-inch conduits, thousands of which line the roads waiting to be installed as part of a new $7 million water system for the area. She found these people reluctant to respond to her questions in a civil manner, and unfortunately portrayed their plight as typical of the housing situation.

m/r's correspondent inspected many such pipes and could locate no one inside. Whether or not they had ever been occupied by humans is no true measure of the area's problem and how natives as well as newcomers are banding together to meet it.

There are those who claim that finding a house is easy compared to driving into Cocoa for Saturday morning's shopping. All traffic from the peninsulas funnels into a two-lane causeway, not even adequate in 1950 when the area's permanent population was 12,000. Now it is triple that.

All businesses except the numerous bars are geared to the past, although the inconvenience of trading with the local merchants is greatly softened by generally low prices for staple items. The one unfortunate exception is groceries. Chain super markets have, up until now, found land too expensive to move in in force.

The crowded condition, reminding transplanted New Yorkers of Macy's Basement on bargain day, is typified by the lone bank whose patrons have trouble finding elbow room in which to fill out their deposit slips. Fortunately, a new and more spacious bank has just opened.

No group in Cocoa is more aware of these detriments to happy living than the city fathers, led by Mayor Garry Bennett, an affable fish merchant and long-time resident. Bennett says: "Good housing and better business facilities are going up just as fast as local capital can provide the wherewithal. Greater Cocoa today is no different than any other boom area."

Bennett points proudly to his newly opened Central Brevard National Bank, an all-new institution located on land reclaimed from the inland waterway and fronted by a highway cloverleaf that will do much to relieve the congestion of traffic pouring into town from the peninsulas.

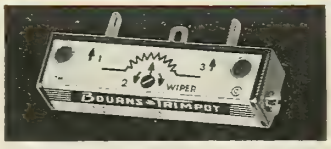
He cites the newly awakened social consciences of industries in the area. Convair, for example, has purchased waterfront property for an employee housing development that will ultimately take 350 families off the private real estate market by offering them fairly priced dwellings and even spreading the small down payment out in a company-carried second mortgage. Fairchild is planning a similar venture, and others will undoubtedly follow suit. On-base military housing for Patrick is already considered adequate.

Bennett has a right to point to a bright future. Even local entrepreneurs, such as Gus C. Edwards, are finally waking up and hocking their souls to put up decent dwellings to ease the strain as well as turn a legitimate profit. Building permits taken out in Cocoa alone jumped 10 times in value in the last two years. Somewhere in this number will be more and better places to live.

It could fairly be asked that since Patrick is not new, especially when time is measured at rocket pace, why hasn't something been done before? The answer lays partly in local inertia but mostly on the shoulders of the Defense Department, which has a habit of moving into peaceful backwaters and deserts around the globe without planning beyond its immediate needs. When satellite civilian industry follows, housing and attendant problems inevitably develop.

Their solution is too large and immediate a job to be practical for private capital. Cocoa could have long since been an oasis for its dedicated newcomers if Uncle Sam had seen fit to exchange just one B-52 for cinder block and stucco. ★

For a Hot Return



Three-stage reentry test vehicle as it leaves launching rail at NACA's Wallops Island, Va. First stage is an HONEST JOHN while second stage is a NIKE booster—both proven components and NACA favorites in high-rate heating studies. The missile's third stage is a solid propellant T-40 and is programmed to fire in a downward direction. Note the extreme low-drag-to-weight ratio configuration. This cone would be useful in studying the heating gradient back along the missile body, as when, for example, disassociation occurs at the vertex of the cone and reassociation near the tail.

BOURNS

announces new TRIMPOT® models for quick assembly

130 TRIMPOT® solder-lug type

You can solder your hook-up wire direct to this instrument, and eliminate splicing. Terminals are standard flat, slotted lugs to provide fast, secure connections.

The silver-plated solder lugs are extremely rugged. Instrument is not affected by soldering iron temperatures.

205 TRIMPOT® for printed circuits

Round pin terminals on this unit may be plugged into holes in your printed circuit boards for dip soldering. Terminals are gold-plated copper, ½" long, .028" diameter, and spaced in multiples of 0.1". Mounting is accomplished by 2-56 screws through body eyelets, or by pins only.

BOTH UNITS PROVIDE a usable potentiometer range of 98%, and low residual resistance either end, 0 to 1%. Low temperature coefficient wire is utilized in the precision wirewound resistance elements.

In all other design features, these instruments are similar to the original Model 120 TRIMPOT. Each is subminiature in size (1¼" x 5/16" x ¼"), and weighs only 0.1 oz. Other characteristics include 25-turn screwdriver adjustment, self-locking shaft, and excellent performance under extreme shock, vibration and acceleration. Units meet or exceed most government specifications. Delivery from stock on standard resistances. Send for Bulletins 130 and 205.

Lockheed Aircraft Corp's. X-17 test vehicle cuts a grotesque figure in the still, moist predawn Florida air as it's readied for firing from Patrick Air Force Base's Cape Canaveral launching site. The job of the X-17 has been to approximate long-range ballistic missile reentry conditions. Velocities on the order of Mach 15 are accomplished by firing the final stage in a downward direction. Data thus gained will contribute to development by Lockheed of the Navy's Fleet Ballistic Missile, POLARIS, as well as to the Air Force's two ICBM projects.

Consisting of a modified SERGEANT first stage, three encased RECRUITS as a second stage and a single RECRUIT third stage, the X-17 from a propulsion viewpoint is a Thiokol product.

Over 40 feet high and weighing six tons, the Air Force X-17 Reentry Test Vehicle is tilted into firing position by a device nicknamed "strongback." Note the telemetry tower and antenna in the foreground. Ideally, the X-17 is fired in such a way that its third stage hits the Atlantic while over the continental shelf, enabling the test nose cone to be recovered.

The Spectacular X-17

The spin stabilizers fire for only a brief moment before they burn out and are flung free (see picture to far right). The X-17 test program is being conducted by Lockheed as part of the Air Force ballistic missile program under the supervision of the Air Research and Development Command's Western Development Division. The knowhow cannot but be helpful in working with the General Electric Co's. Missiles and Ordnance Systems Department to whom Lockheed has given a contract for POLARIS nose cone development.

One of a kind

Among the many requirements for heat elements in industry today are those demanding virtually one-of-a-kind design.

Since such requirements normally cannot be met by loom weaving, Safeway technicians fabricate odd-shaped elements individually. Circles, half circles, cutouts, tapers and compound shapes are just a few of the elements fabricated in this fashion and produced in quantity.

Insulation, too, must provide for the characteristics of specialized applications. Safeway produces a wide variety of elements insulated with neoprene rubber, silicone rubber or reinforced plastics.

If you have a problem that requires heat, let Safeway engineers study your requirements and—without obligation to you—submit an appropriate recommendation.

For your copy of a fact-filled folder, write to:

Safeway HEAT ELEMENTS INC.

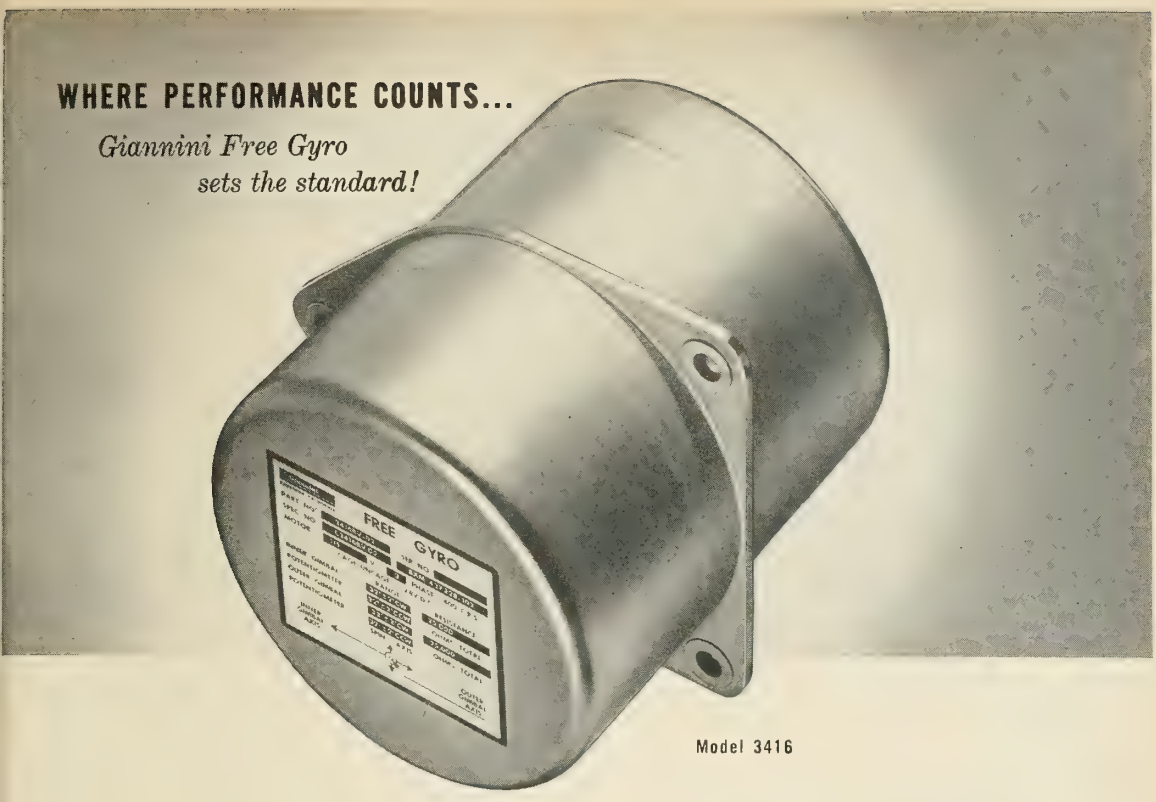
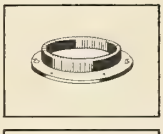
NACA's 8000 MPH Rocket



Carefully protected from the weather by a polythene bag, a blunt high-drag-to-weight ratio nose cone awaits launching for 8000 mph reentry test. This rocket test vehicle consisting of an HONEST JOHN first stage, NIKE booster second and third stages, RECRUIT fourth stage and a Thiokol T-55 fifth stage is the latest of NACA's hypersonic reentry rockets. It is shown about to be launched from NACA's Pilotless Aircraft Research Station, Wallops Island, Va. The vehicle attains its record speed by firing the last three stages after the rocket has "gone over the top." In previous similar work, an NACA four-stage rocket attained a speed of Mach 10.4 (6864 mph) and an altitude of almost 200 miles. The speed of this five-stage vehicle has never been officially announced. Aside from telemetered data, the missile's performance is monitored by visual, electronic and special photographic aids. From the first through the fifth, companies responsible for the various stages include Douglas Aircraft and Emerson Electric (HONEST JOHN); Ingersoll Div., Borg-Warner Corp. and Goodyear Aircraft (NIKE boosters); and Thiokol (RECRUIT and T-55).

WHERE PERFORMANCE COUNTS...

Giannini Free Gyro sets the standard!



Model 3416

GIANNINI FREE GYRO

Outstanding in reliability and accuracy, the Giannini Model 3416 Free Gyro has been designed for today's most advanced airborne control and telemetering systems. Now in quantity manufacture, it has been chosen as standard equipment on production missiles and is used for flight test instrumentation on a number of aircraft. From its precisely balanced rotor-gimbal system to its rugged structural outer shell, this instrument offers more significant features than any other free gyro available.

CAST STAINLESS STEEL STRUCTURAL MEMBERS
having compatible temperature coefficients and providing structural rigidity.

TWO PRECISION POTENTIOMETER PICKOFFS
for simultaneous measurement of angular displacement in two mutually perpendicular axes.

REMOTELY ENERGIZED ELECTRICAL CAGE-UNCAGE SYSTEM
with indicator circuit for each.

LOW DRIFT DURING HIGH VIBRATION
due to precise dynamic balance, structural strength and CG mounting.

HERMETICALLY SEALED CASE
capable of withstanding climatic and altitude hazards.

For further information, write for Bulletin 3416.

Electronics Aerodynamics Propulsion

The Johns Hopkins University
Applied Physics Laboratory

ANNOUNCES

. . . important openings on our guided missile research and development staff for men who wish to identify themselves with an organization whose prime purpose is scientific advancement.

Because the Applied Physics Laboratory (APL) exists to make rapid strides in science and technology, staff members require and receive freedom to inquire, to experiment, to pursue tangential paths of thought. Such freedoms are responsible for findings that frequently touch off a chain reaction of creativity throughout the organization. As a staff member of APL you will be encouraged to determine your own goals and to set your own working schedule. You will also associate with leaders in many fields, all bent on solving problems of exceptional scope and complexity.

Equidistant between Baltimore, Md., and Washington, D. C., our new laboratory allows staff members to enjoy suburban or urban living and the rich cultural, educational and research facilities offered by both cities.

Openings Exist in These Fields:

DEVELOPMENT: *Stability and control analysis; ramjet engine design; preliminary design and wind-tunnel testing; electronic guidance and control systems.*

RESEARCH: *Interference and heat transfer phenomena; internal aerodynamics; hypersonics, turbulence, shock wave phenomena, combustion.*

SEND NOW FOR OUR NEW 30-PAGE PUBLICATION DESCRIBING IN DETAIL THE SCOPE OF THE LABORATORY'S PROGRAMS AND THE UNIQUE ENVIRONMENT IN WHICH STAFF MEMBERS WORK AND LIVE.

Propulsion Notes

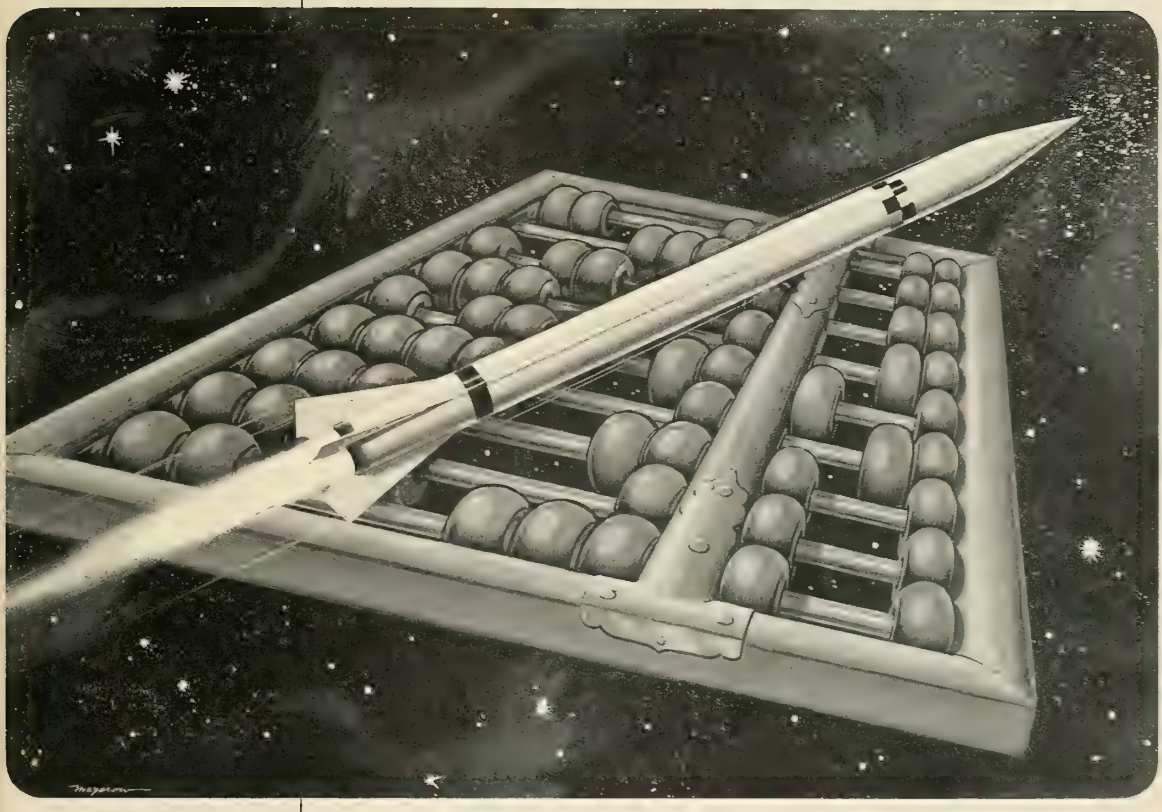
By Alfred J. Zaehringer

Ionization as the result of the combustion of fuels at simulated altitudes in oxygen was studied by the Naval Research Lab. At an instrument frequency of 24 x 10^6 no attenuation was found for hydrogen sulfide, carbon disulfide, or hydrogen. Ionized fractions: about 10^{-4} for acetylene, ethanol, and gasoline; and 10^{-5} for ammonia. These figures were about 6 times greater than predicted.

Aerojet has been granted a patent (US 2,771,739) for suspensions of lithium, beryllium, boron, aluminum, magnesium, phosphorous, potassium, or sodium in liquid hydrocarbons such as gasoline. Oxidants are WFNA and RFNA. Use is for hypergolic bipropellant rocket systems.

Burning rates of solid propellants are said to be increased 100-200% by addition of hydroxylamine perchlorate in a new patent (US 2,768,874). The crystalline compound is hygroscopic, decomposes at 120°C, and can be initiated by impact of a 2 kg weight falling 15 cm.

NACA has released its findings of research on nitric acid systems. Lewis Flight Propulsion Lab has found that RFNA with 19% N_2O_4 and 3% water gave the best low freezing point and short ignition delays. Some 17 acids were tested. Triethylamine made for the best blend of aromatic fuels down to —76°F. At lower temperatures, 30% ortho-toluidine in triethylamine gave the shortest ignition delay with RFNA. In general, it was found that ignition delay decreased with increased oxygen content and decreased with temperature increase.



High energy Aeroplex solid propellant (Aerojet) has an exponent of burning rate only slightly greater than ammonium nitrate-base propellant. Typical burning rates (in/sec) over a chamber pressure range of 500-2,000 psia: ammonium perchlorate, 0.6-1.4; potassium perchlorate, 0.4-1.2; mixed ammonium nitrate and ammonium perchlorate, 0.1-0.18; ammonium nitrate, 0.04-0.08. Aerojet also reports a "medium energy" ammonium perchlorate propellant that plateaus at about 0.3 in/sec. The burning rate is constant from 1,000-2,000 psia.

Hydrogenation of unsaturated polycyclic hydrocarbons gives jet fuels with higher heats of combustion than conventional fuels (US 2,765,617). Monsanto claims a typical heat of combustion of 136,800 BTU/gal.

Patents were granted to Phillips Petroleum for fuels in liquid propellant systems. Piperidine and substituted piperidines are claimed to be hypergolic with acids, peroxide, nitrogen tetroxide, oxygen, or ozone (US 2,771,737). Another (US 2,769,304) is concerned with hypergolic fuels of low freezing point and short ignition delay. The fuels are composed of 10-87% volume pyrrole and 13-90% volume of ethylenimine and other oxidizers. Combustion stabilizers are chlorides and naphthenates of iron, zinc, or cobalt.

Sign of the times: Olin Mathieson made its first tank car shipment of hydrazine recently from its Lake Charles, La. plant. Commercially available since 1953, deliveries have all been in small lots.

American Rocket Co. is entering the liquid propellant field with the introduction of a new-type, high-energy monopropellant. It is a liquid with very low freezing point and high boiling point. Other features: very high density, ease in handling, low cost. The new material has been under development since late 1956.

Computers for Missile Guidance

The Jet Propulsion Laboratory is a stable research and development center located north of Pasadena in the foothills of the San Gabriel mountains. Covering an 80 acre area and employing 1700 people, it is close to attractive residential areas.

The Laboratory is staffed by the California Institute of Technology and develops its many projects in basic research under contract with the U.S. Government.

Opportunities open to qualified engineers of U.S. citizenship. Inquiries now invited.

The abacus is a very ancient and useful computing device in the hands of a person versed in its use. However, the requirements for speed and accuracy in computing the functions necessary for modern missile guidance have obsoleted all man-operated devices, creating a need for computing systems previously considered impossible.

The Jet Propulsion Laboratory pioneered in the application of analog computing techniques to missile guidance systems and, to maintain its leadership in this field, constantly searches for new techniques that will make optimum use of magnetics, transistors and other modern computing components.

The successful application of these techniques to missile systems under development requires designs that will perform properly under the adverse environments found in today's guided missile. A degree of accuracy and extreme reliability, previously thought possible only under controlled laboratory conditions, is now a reality because of improved instrumentation techniques and development of highly accurate instrumentation equipment. This has been successfully applied to development of special purpose equipment for missile guidance.

The JPL guidance computer group, now engaged in research and development work encompassing electronic, mechanical, electromechanical and servo computing systems and their application to missile guidance and control, now offers attractive opportunities for truly creative engineers interested in advancing the state of computer art.

Send your resume today for immediate consideration.

Moving Averages Police Solid Rocket Output

At Air Force Plant 66, McGregor, Texas, Phillips Petroleum Company, through its Rocket Fuels Division, is engaged in the development and manufacture of solid propellant rockets of various kinds and sizes. Several rocket types are nearing the qualification stage. The M15 has progressed through the stages of laboratory experimentation, pilot plant production, and qualification, and is now in large scale manufacture for service use. This unit is powered by a rubber-base, extruded, solid propellant grain.

Statistically sound sampling plans are in use for the acceptance of incoming chemicals and metal parts. A relatively small variation in a chemical material from specifications may result in either expensive difficulties in processing or rejection of propellant. A change of source in certain materials may require process alterations. Quality control in processing is equally essential since even such variations as mixer-to-mixer differences in intensity of mixing must be considered. Wherever sampling or testing is expensive or destructive, inspection by variables rather than by attributes plans reduces cost.

Attributes inspection is, of course, inspection for the presence or absence of a certain characteristic or attribute.

Variables inspection is the actual measurement and recording of a quantitative value, such as 2.93 inches. This inspection yields data telling not simply whether a dimension or quantitative characteristic is within specification, but also how far it is inside or outside of the specified limits. Equal assurance can be attained with a much smaller sample through the use of variables sampling plans than through the use of attributes plans.

For ballistic acceptance of the M15 JATO, consideration was first given to lot-by-lot acceptance using variables sampling plans. A lot, for purposes of this paper, is a group of consecutively manufactured rockets produced under the same set of processing procedures from materials having no significant changes affecting end performance. Such a lot may be considered as homogeneous in nature, with no abnormal variations in any performance characteristic from the lot average for that characteristic. Ordinary lot acceptance would require that each lot be completely manufactured prior to selection of random samples to be fired. This requirement led to one of two alternatives:

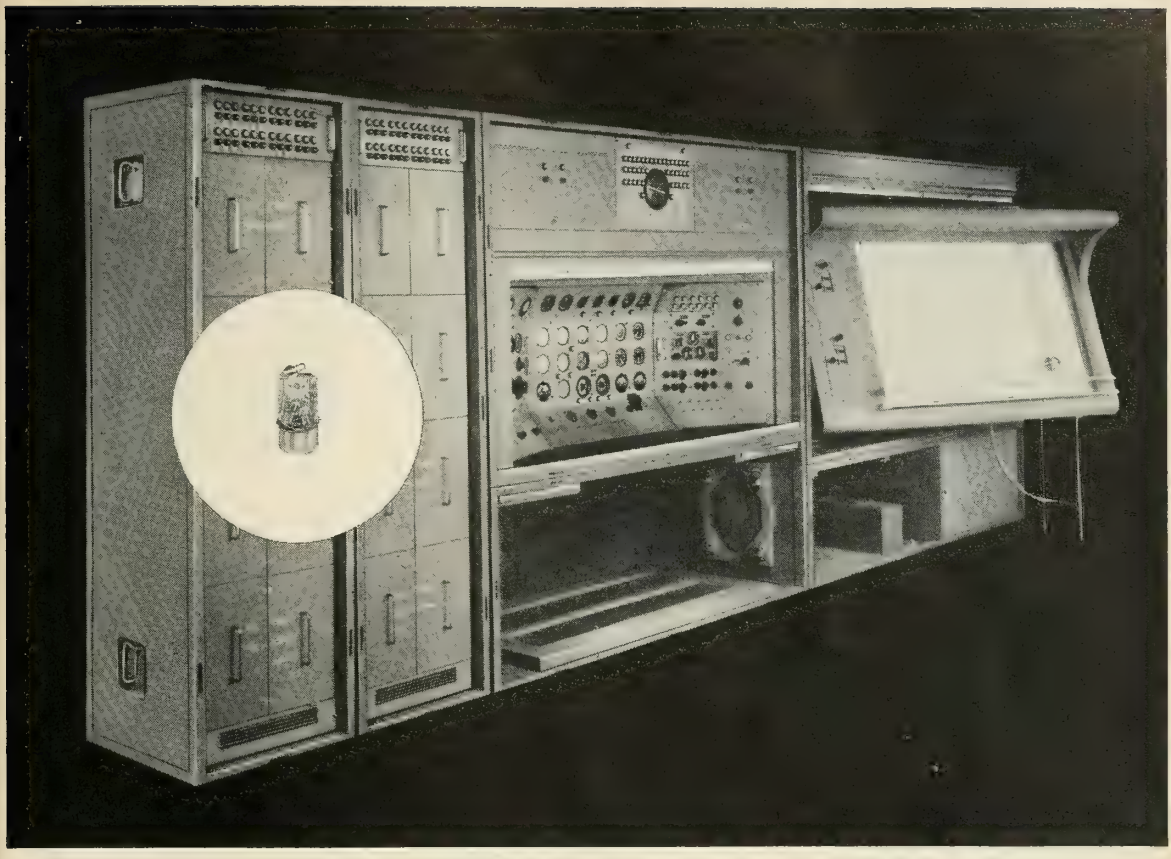
Either lots had to be kept to a minimum size (100 to 300 JATO units), to allow for minimum storage and delay prior to acceptance, with the disadvantage that variables sampling would lose much of its sensitivity and require more destructive testing, or larger lot sizes and more storage were required. Disadvantages would be the cost of storage facilities and the increase in delay in information from acceptance firings.

Neither alternative was very satisfactory. After a study of the problem, it was decided that maximum sensitivity to trend changes in ballistic parameters, greatest economy, and minimum delay of information to manufacturing personnel could be achieved by adapting a variables fractional continuous sampling plan for ballistic parameters, as explained in the following paragraphs. The basis for this type of sampling plan was presented by Harry G. Romig in a paper entitled "New Statistical Approaches in Aviation and Allied Fields," presented at the Aircraft Quality Control Conference at Dayton, Ohio, in November, 1953.

The plan as adapted for M15 JATO calls for a lot to be one month's production, unless some change in the process occurs requiring a change of lot designation. For acceptance and identification purposes, a one-month production lot is broken into sublots representing the production of one eight-hour shift. Ballistic acceptance sample units are chosen from these sublots. Every precaution is taken to insure a completely random choice. Control is maintained of the calibration of the instruments and test equipment used in firing the sample units, and of the conditioning temperature of the units prior to firing.

Acceptance sampling is carried out on a fractional continuous basis through the use of a three-point moving average for each ballistic parameter. In other words, the ballistic parameters resulting from every acceptance firing are respectively averaged with the same parameters from the preceding and succeeding firing. Firings are made in equal numbers of units conditioned to the three required temperatures, hot, cold, and normal; and all ballistic parameters are adjusted to represent the firing of a unit conditioned at normal temperature. Acceptance or rejection is on the following basis:

1. From the production of the first sublot under this plan, three production units are selected at random and fired, one at each of the three temperatures. Adjusted values of all ballistic parameters must individually meet the limits specified and fall within upper and/or lower reject limits.



2. If Paragraph 1 is met, then one per cent of units produced (and not less than one unit), randomly selected from each sublot, are fired, and a moving average maintained of the results of the last three firings. This moving average must remain within limits for averages, and individual parameter values for the last firing must also remain within acceptable limits.

3. If an individual firing of a sample unit yields any ballistic result which fails to meet limits for individual units, then the sublot represented by that unit is rejected. If the moving average for any parameter fails to meet limits for averages, then the three sublots represented by that average are rejected.

4. Alteration of firing temperatures is done in such a manner that units from any one eight-hour shift will not always be fired at the same temperature.

It has been apparent from the results to date that the fractional continuous variables acceptance sampling plan for ballistic parameters of M15 JATO has been much more feasible than lot-by-lot variables sampling. It has been more economical, since it has resulted in much less than half the number of firings necessary to yield the same assurance using a small lot variables sampling plan and has made unnecessary any provision for additional storage capacity for large lots. It has been more rapid in furnishing usable information and more sensitive to defective material than would lot-by-lot acceptance of small lots of units.

One area of caution regarding the use of this plan concerns the greater degree of sensitivity afforded by the moving average for the various parameters. It is quite possible, due to a slight shift in the mean for any certain parameter, for one or more sublots occasionally to be rejected when in actuality all units in the sublot are within individual limits. This problem cannot be considered a defect in the sampling plan, since the sensitivity of the moving average is desirable. However, it does necessitate the recognition by the procuring agency, as well as the manufacturer, that sublots which are rejected by a moving average found slightly outside limits, should be evaluated through additional firings.★

From miniature components to integrated systems

AMF has electronics experience you can use

• AMF experience in electronics covers practically every area of the field, from design through production, of individual components and complete systems, for both government and industry.
• AMF has organized development and production teams experienced in the latest mechanical and electronic techniques. These teams, located throughout AMF, achieve the fine balance so necessary to produce efficient, reliable equipment.

• Particular AMF electronics capabilities and products include . . .

Data Processing and Display • Training Devices and Simulators • Antennas and Mounts
Communication Systems • Low-frequency Radar • Electronic Warfare Devices
Air Navigation and Traffic Control • Missile Check-out Equipment • Electric Motors
Guided Missile Support Equipment • Industrial Relays • Silver-zinc Batteries

Reinforced Plastics for Rocket Applications

Reinforced plastics are being used not only in secondary, but in primary rocket structures as well where successful performance is essential. For short, one-shot operations their temperature tolerance often exceeds that of their metallic counterparts. The unique service conditions for rocket-motor hardware often necessitate a search for unconventional materials or the adaptation of existing materials to an unconventional use. Adiabatic flame temperatures of several thousand degrees fahrenheit for relatively long exposure periods, are routine requirements for rocket-motor and missile manufacturers. High gas velocities at these elevated temperatures often are encountered. The thermal properties of reinforced plastics make these materials desirable when compared to metallic structures. Furthermore, combinations of reinforced plastics and metals can effect significant weight reductions.

Here are just a few of the rockets and missiles shapes capable of being fabricated of reinforced plastics, which promise increased flexibility and economy.

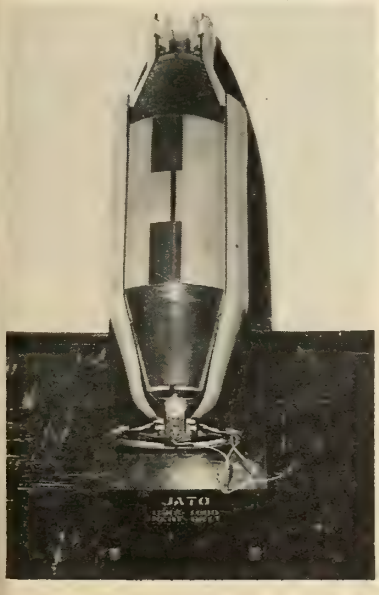
Founded in 1942 by Dr. Theodore von Karman, the Aerojet-General Corp. has expanded its activities to include almost all possible applications of rocket power. Recognizing the potential of reinforced plastics in producing lighter weight, more efficient, or otherwise more suitable structures, Aerojet management encourages continuing activities in development of novel designs involving reinforced plastics. Some of these developments are finding their way into non-rocket applications.

George Epstein, J. W. Ederhardt, Jack Goldberg and H. A. King of Aerojet recently presented a paper, "Reinforced Plastics for Rocket Applications," at the Annual Conference of the Society of the Plastics Industry. This article extracts that paper.

Glass reinforcements are used primarily in conjunction with polyester, epoxy, elevated-temperature-resistant phenolic, and silicone resins. Asbestos reinforcements, refractory powders, and other filler materials are also used. Fabrication techniques include layup, matched-die molding, filament winding, casting and adhesive bonding.

The advantages of reinforced plastics in rockets include: high strength-to-weight ratio; desirable thermal insulating properties; ease of fabrication into complex configurations; use of non-critical materials; wide versatility in selection and formulation of resin-curative-filler (reinforcement) systems; low-cost tooling and fabrication techniques; resistance to various environments, e.g., moisture, sea water, weather, fungi, solvents and fuels, acids and alkalies; non-magnetic properties; excellent electrical properties.

Reinforced plastic structures are employed in rocket applications for various temperature exposures. Polyester and epoxy resins usually are used for service at low temperatures (between −65 and + 200°F). For service at intermediate temperature ranges (200 to 500°F), and at high tempera-



tures (500 to 1000°F), heat-resistant epoxy, phenolic, triallylcyanurate-modified polyester, and silicone resins are employed, with silicones usually limited to long-duration or repeated exposures. Reinforced plastics also are used when exposure is required for extremely short durations (several seconds or less) to temperatures of over many thousands of degrees.

Aerojet developed the modified-epoxy-resin formulation employed in glass-reinforced-plastic liners for insulating nozzle adapters in rocket motors during operation of a safety device. Service conditions require exposure to temperatures of over 3000°F for several seconds in a high-velocity gas stream. Fabrication costs of this structure are approximately one-half those for a "conventional" heat-resistant phenolic resin.

A JATO unit contains several reinforced-plastic components. The Tee baffle is subjected to gas temperatures of approximately 3800°F and gas velocities up to several hundred feet per second for a duration of approximately 15 seconds. In addition to providing a thermal barrier, this phenolic-resin, glass-fabric-reinforced structure suppresses instability which might occur during combustion of the solid propellant. A reinforced-plastic cone is also used in this rocket, serving as a safety-diaphragm deflector. An external exhaust deflector of glass-reinforced-phenolic-plastic employed with the JATO in order to confine the high-velocity exhaust jet and deflect it from adjacent aircraft surfaces. In a normal firing, the high-velocity exhaust gases

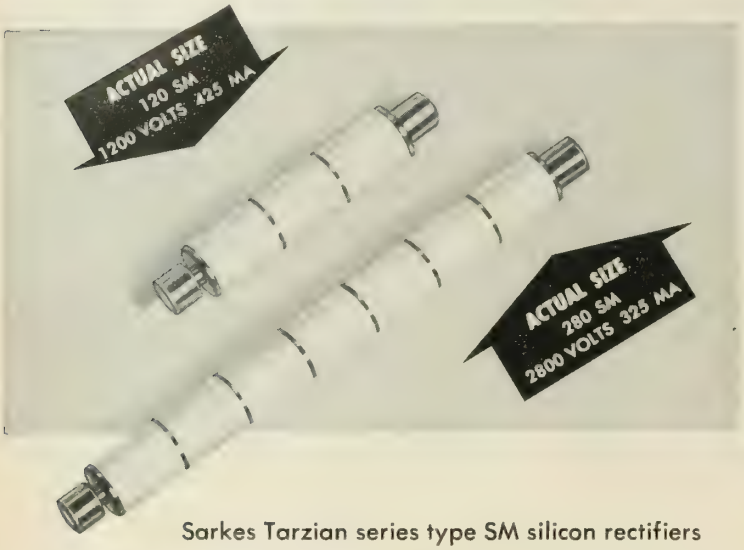
Cross-section of a rocket motor showing the increasingly important role being played by reinforced plastics.

CENTURY MODEL 409D
RECORDING OSCILLOGRAPH

Numerous agencies engaged in the manufacture and evaluation of missiles have turned to the Century Model 409D Recording Oscillograph as a reliable means of collecting missile performance and control data.

On-board mounting eliminates the necessity for the costly and often not reliable RF link.

The ruggedness and reliability of this 12-channel oscillograph have been demonstrated many times. One agency reports having recovered 42 satisfactory record rolls out of 43 firings. Another, using special mounting configuration, reports recording at 60 G's without damage.



This 13 lb. instrument is compact enough to be installed in most missiles and all electrical connections including remote control are accomplished through a single multi-pin AN connector.

EXPORT: AD AURIEMA, INC., NEW YORK CITY

are confined by the plastic part, which is capable of being used for several normal firings.

Honeycomb plastic sandwich was fabricated for a stabilizing-control-surface part on an advanced *Aerobee* sounding rocket. Elevated-temperature-resistant, reinforced-plastic skins, core, and attachment edges are joined with a heat-resistant structural adhesive. The leading edge of this sandwich part has a herring-bone pattern designed to provide optimum resistance to erosion during high-speed flight.

A number of the guided-missile warheads have made extensive use of glass-reinforced-plastic structures to take advantage of minimum parasitic weight and increased strength-to-weight ratio, and to provide versatility in design. Warheads using reinforced-plastic structures and adhesive-bonded-metal components have successfully withstood the most severe military environmental tests and, in many cases, warheads subjected to these tests have been completely usable when their metal counterparts would have been rendered completely useless.

Filament winding provides a means for obtaining the maximum strength-to-weight ratio in reinforced plastics by locating each strengthening filament of glass at its optimum position. Thus, if the structure is to be stressed in one direction only, all (or nearly all) of the filaments can be applied in such a direction as to counteract this force. Pressure spheres made this way have been produced in diameters from 1½ to 21 inches and varying in design burst pressure from less than 100 to over 10,000 psi.

Such spheres are used as pressure tanks in aircraft hydraulic systems, in missiles and rockets to pressurize liquid propellants, and high-pressure containers in general. Two 12 inch filament-wound spheres mounted in an *Aerobee* sounding rocket. This type of installation was employed in the widely-publicized "Firefly" project of the Air Force. Nitric oxide gas was contained at a pressure of 3000 psi and released at an altitude of 56 miles during upper atmosphere research investigations.

Plastics engineers in the rocket industry are pioneering in the areas of high temperature and high-pressure applications of reinforced plastics. Many of the accomplishments to date have been achieved primarily as a result of close cooperation between material suppliers, engineers, and fabricators. It is expected that continuing cooperation in the development of new materials and techniques will promote rapid expansion in the utilization of reinforced plastics in the rocket industry.

An example of the Bendix Red Bank complete line of high-altitude and missile inverters

As aircraft and missile performance continue to step up, Bendix Red Bank designers continue to lead the field in developing new, high-performance inverters and power packages.

We now offer a complete line of inverters from 6 VA to 5,000 VA, including advanced special-application units and missile type power packages like the one shown above.

If we don't have an inverter to meet your specific needs, we'll design one. For full details, write RED BANK DIVISION, BENDIX AVIATION CORPORATION, EATONTOWN, NEW JERSEY.

West Coast Sales & Service: 117 E. Providencia Ave., Berbank, Calif.
Export Sales & Service: Bendix International Division, 205 E. 42nd St., New York 17, N.Y.
Canadian Distributor: Aviation Electric Ltd., P.O. Box 6102, Montreal, Quebec

Double sealing . . . inorganic construction make

New 'Diamond H' Series S Relays Doubly Dependable

in dry circuits

Separately sealed coils isolated from completely inorganic switches within their hermetically sealed cases make these new "Diamond H" Series S aircraft type 4PDT relays supremely reliable in dry circuits.

Physically and electrically interchangeable with "Diamond H" Series R relays, widely used in guided missiles, computers, jet engine controls, automation control systems and similar critical applications because of their broad range of performance characteristics, Series S relays will permit intermixing of dry and wet circuits safely.

Contacts are specially processed and cleaned before assembly; subsequent contamination from gases off the coil insulation is prevented by the coil seal. The switch mechanism has been simplified and is completely inorganic to eliminate other possible causes of malfunctioning.

Standard contact ratings include 30 V., D. C.; 115 V., A. C.; 2, 5, 7-1/2 and 10 A.; resistive; 2 and 5 A., inductive, with special ratings available to 350 V., D. C., 400 MA, or other combinations including very low voltages and amperages, or amperages up to 20 for short life requirements. Coils are available with resistances of 1 ohm to 50,000 ohms. Operating time of 24 V. models is 10 ms. or less; dropout less than 3 ms.

Vibration resistances range from 10-55 cycles at 1/16" double amplitude to 55-2,000 cycles at 20 "G"; operational shock resistances to 50 "G" plus, and mechanical shock resistance up to 1,000 "G". Nine standard mounting arrangements, plus a ceramic plug-in socket, are available. The unit displaces only 1.6 cubic inches, excluding terminals.

"Diamond H" engineers will be happy to work out a variation to meet your specific requirements. Tell us your needs . . . or write for bulletin on new "Diamond H" Series S relays.

THE HART MANUFACTURING COMPANY

161 Bartholomew Avenue, Hartford, Conn.

engineering briefs

Expanding exotics: Callery Chemicals has broken ground on a $38 million plant that will grind out high energy boron fuels for the Navy. By 1958 the facility will produce a compound called "Hi-Cal" which was developed by Armour Research Foundation. Olin Mathieson is starting construction on a $36 million facility at Model City near Niagara Falls for the production of "Zip" chemical fuels for USAF and a smaller plant at the same site for the Navy. Meanwhile, tank car quantities of boron trichloride will be available by Stauffer Chemical at its Niagara Falls plant. Stauffer is also planning to produce other metal chlorides in a new $1 million expansion.

*

Marriage of propulsion and guidance looks near for Thiokol. The propellant firm recently acquired National Electronics Labs of Washington, D. C. Recently, Aerojet expanded its electronics operations (Avionics Div.) under an $880,000 program. Another propellant firm—Atlantic Research—is also in electronics and is marketing a line of transducers, amplifiers, and even a solid propellant strand burner.

*

Position of normal propyl nitrate is uncertain. After a recent accident, one service is considering abandoning its use. AMF is still said to be doing work on NPN and GE has come out with a pump to handle the nitrate. AMF is said to be going great guns on use of ethylene oxide—mostly APU's for the ICBM program.

*

Studies in the controlled thermal decomposition of cellulose nitrate may lead to clues in the complex combustion mechanism of double base solid propellants. Work at Aberdeen Proving Ground is being carried on with propellant type cellulose nitrate. In ignition and combustion at low pressures, a solid nitrated oxycellulose low polymer is obtained. At somewhat higher pressures a whole line of organic fragments resulted. Some HCN was also found at all pressures and is believed to come from residual solvent.

*

Developments in aircraft nuclear power plants and power reactors may usher in a new age of steam power for conventional aircraft. One firm is replacing the pile with a modern fuel combustor and uses compound vapor systems to run a closed cycle turbine. Now being investigated are water, ammonia, and isopropyl biphenyl.

Where do you belong in IBM Military Products?

Systems Design Engineer: Before his recent promotion, this man planned electronic digital computers through development and evaluation of logical configurations and electronic circuits. He used linear and pulse circuits employing transistors and other semi-conductors; evaluated test data from development models for speed, reliability, data processing capabilities. *Could you handle his responsibilities?*

Transistor Logic and Circuit Designer: Also promoted recently, this man formerly planned, tested and evaluated advanced electronic digital computer circuitry. He guided the building of original circuits through the development model stage. Other assignments in associated fields: advanced component development, specialized projects in ferromagnetics, optics. *Could you handle his responsibilities?*

Challenging jobs are now open!

Organized only 20 months ago, IBM Military Products Division has grown enormously, opening up career opportunities to engineers and scientists in all these fields:

- Circuit Development
- Components
- Cost Estimating
- Digital and Analog Systems
- Electronic Packaging
- Electronics
- Field Engineering
- Heat Transfer
- Human Engineering
- Inertial Guidance
- Installation
- Mathematics
- Mechanical Design
- Optics
- Physics
- Power Supplies
- Programming
- Reliability
- Servo-Mechanisms
- Systems Planning and Analysis
- Technical Publications
- Test Equipment
- Transistors

At the new plant and laboratory in Owego, N. Y., IBM designs and manufactures advanced airborne analog and digital computers for Air Force bombing-navigational equipment. At the new Kingston, N. Y. facilities, IBM builds the world's largest electronic computers for Project SAGE, part of our nation's giant defense net.

The electronic computer field offers one of the best ground-floor career opportunities today. Economic experts rank the electronic computer in importance with automation and nucleonics in growth potential. Sales at IBM, the recognized leader in the field, have doubled, on the average, every 5 years since 1930. Engineering laboratory personnel quintupled in the past five years. Future expansion plans offer even better opportunities.

As a member of IBM Military Products, you enjoy the stability and security of the IBM Corporation, plus the opportunity to progress in any other IBM division. Promotions open up frequently from continuous growth. The "small group" approach assures recognition of individual merit. Salaries are excellent and company-paid benefits set standards for industry.

Where would you like to work for IBM?

This map points out key IBM plants and laboratories, including the Military Products facilities at Owego and Kingston, N. Y. Limited openings are available at many flight test bases and SAGE computer sites across the nation.

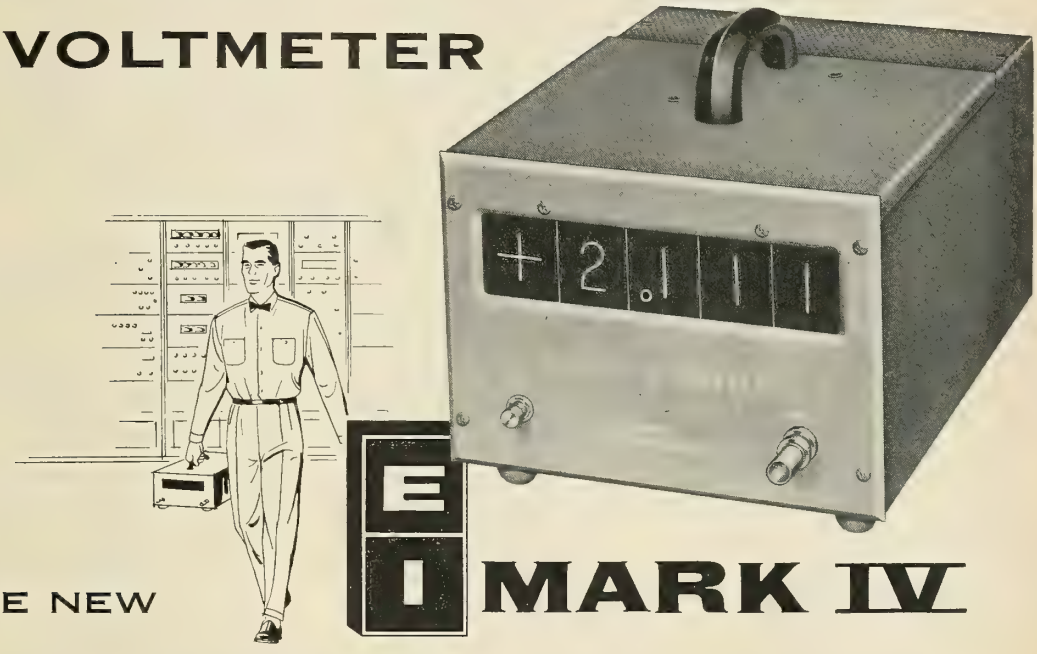
Missile Miscellany

From a combat soldier who should know, this capsule appraisal of a missile family: Redstone—a monstrosity, payload too big for range; Corporal—a misfit, range, complexity and logistics too much for tactical requirement; Honest John—the soldier's pal, highly mobile, designed for the job; Lacrosse—a precision pillbox getter with five-yard maximum error per mile range, truck transportation with go-nogo box the size of TV creepy-peepy; Little John—designed to cut out need for AF close support; Dart—Army nearly did to a good French design what Martin and AF did to the Canberra.

And while this page is apparently picking on other people's pet projects, developing preference for Nike over Talos may be due to the fact that Talos electronic gear requires over 250 "wall cabinets." Nike takes much less.

A telephoned warning this page respects, quoted by a Government man of science from University of Chicago bio-chemist Jaques Loeb: "If a man claims there is a gaseous verterbrate floating around the atmosphere, it is clearly his duty to prove it and not the duty of every other scientist to disprove. Otherwise we'd spend our lives disputing the claims of every charlatan and crackpot."



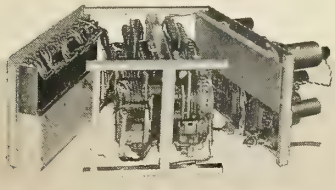
In contrast, this from a physicist turned editor: "Einstein's was an unfettered mind. He ignored the dogmas of ages past and hypothesized solely on the basis of observed phenomena and, thus, was able to provide a wholly new approach to man's universal environment. Now there's danger this product of a free mind will be used by men of science as an excuse for restricting their own thinking."

Basic Army strategy in the AF-Army squabble is aimed at keeping ABMA in the Army and in one piece. Reasoning is that roles and missions decision denying Army the right to use IRBM weapons will sooner or later be reversed, and Army wants to have its hotshot weapons development group intact when that happens.

And a tip to missile peddlers: It's odds on the recent U.S.–U.K. Bermuda deal will give Britain choice of Thor or Jupiter: Nike or Talos. Same for France. These prototype agreements will set pattern for other NATO powers where U.S. will supply hardware but not manpower for manning European missile bases.

Now quick and fast across the spectrum—Unstable subatomic particles accelerated to near-light velocities decay more slowly than they do at rest, which may be first man-made evidence of Relativistic time-lengthening . . . will close observation of Saturn's spinning rings give similar support to Relativity's length-velocity relationship? . . . Wernher von Braun's back to his jig-saw puzzles, dreaming up a super-Jupiter-C, maybe? . . . a future m r contributor tells of a BBIM, Buoyant Ballistic Inertial Missile that doesn't require any propulsion to go hundreds of miles . . . AF has fixed the external configuration of the Thor; anything to be changed will be internal—a Jupiter in Thor's clothing, maybe . . . lest we forget, the same fuel that smoked up grampa's lampshades will power man's first venture into outer space . . . from NACA director Dr. Hugh Dryden out of context at Congressional hearing: "There is no doubt missiles are coming." . . . while a Regulus with extra fuel tanks has made a successful RATO launch, word seeps through that air-to-surface-ship Petrel will be phased out to make way (and money) for higher priority projects . . . brief word of work at Aerojet on underwater pulsejets recalls Dr. Fritz Zwicky's earlier claim that ramjets can run through earth as well . . . a proprietary-minded technical salesman wonders about the system whereby an overall missiles system monitor also designs and manufactures products in competition with contractors whose latest developments he monitors . . . NACA's A. M. Rothrock says turbojets are good to Mach 3; ramjets, from Mach 3 to Mach 6; and rockets, from Mach 6 to Mach 25 . . . and to the right appears a good replica of how results of years of effort and many dollars expended sometimes turn out . . .

NOW! A PORTABLE, PRECISION DIGITAL VOLTMETER



THE NEW E-I MARK IV

This newest E-I instrument provides the perfect general-purpose voltmeter for both laboratory and field use.

Operation is completely foolproof; no manual adjustments or calibrations are required. Measurements are made automatically and results presented digitally with easy-to-read, 1"-high numerals, arranged in line.

A new electronic amplifier design (reducing the number of tubes to only eight!) and advanced miniaturization techniques have reduced the overall size of the new Mark IV to only 7½" x 9" x 11", and cut the weight to 28 pounds.

Ask your local E-I representative to give you the complete story, or write direct for our new brochure.

UNUSUALLY EASY TO SERVICE

The one-piece hood houses three distinct sub-assemblies: amplifier, power and reference supplies; balance circuit; and read-out. Each sub-assembly is pivoted for excellent accessibility to all parts.

SPECIFICATIONS

Display: four digits, polarity, decimal point.
Range: 0.001-999.9 volts dc.
Ranging: automatic.
Polarity: automatic.
Accuracy: 0.05%, ±1 digit.
Input impedance: 11 megohms.
Average balance time: 1 second.
Calibration: self-calibrated.
Stability: 0.003%/C°.

evaluate

The proof of any guided missile is its performance. Not only is it necessary to provide accurate trajectory data in order to determine its effectiveness, but this must be made immediately available.

To meet both requirements is the purpose of the AN/FPS-16 instrumentation radar. This is the first radar developed specifically for Range Instrumentation. It has demonstrated its ability to track with accuracy in darkness, through clouds—under any atmospheric conditions—over extended ranges, and to yield data that can be reduced almost instantaneously to final form. This unit can also be assigned to plot performance of missile, satellite, drone and other free space moving targets.

In the past, this data has depended upon optical devices, triangulation systems with long base lines and precision limitations, modified radar equipment and data reduction methods often requiring months for computation. The immediate availability of data evaluation provided by the AN/FPS-16, now being built by RCA under cognizance of the Navy Bureau of Aeronautics for all services, is a great forward step in Range Instrumentation.

NEW MISSILE PRODUCTS

HIGH PRESSURE GAS BOOSTER

A new high pressure gas booster developed by Greer Hydraulics, Inc. for testing rocket engines and components is capable of boosting pressures up to 10,000 psi at nominal flows up to 10,000 scfh.

The Greer unit, designed to deliver uncontaminated boosted gas, is proposed for a variety of missile and rocket uses. According to Greer, portable and stationary large-capacity units can be remotely controlled for charging a missile receiver before launching. A smaller stand is adapted to checking missile components, gases and pressure switches.

For dynamic check of missile components, large-capacity stands will supply large continuous flows and can be supplied with gas-recovery features to conserve helium. Other portable, low-capacity models can be used to supply uncontaminated gas pressurization to missiles or components at launching sites.

Circle No. 210 on Subscriber Service Card.

MISSILE FAN

A new landmark in miniaturization is the claim of Rotron Manufacturing Co. for its 2 in. diameter, 1½ in. long Aximax fan to cool missile electronic equipment.

Of vaneaxial design, the Aximax II features inside-out motor construction wherein the electrical rotor and air-moving impeller are integrally cast in one piece. Unit weighs only four ounces and is rated to move 62 cubic feet per minute of air at free delivery and 43 cfm at 2 in. static pressure.

New fan operates at 20,000 rpm, is wound for 400 cycle a-c, either 200 volt, three phase or 115 volt, single phase.

Circle No. 212 on Subscriber Service Card

VIBRATION TESTER

New "economy" vibration test machine introduced by The Ahrendt Instrument Co., subsidiary of Litton Industries, weighs only 30 lbs. and will handle testing of small items up to five pounds.

The Model 14-28 test machine conforms to frequency and amplitude requirements of MIL Standard No. 202 and is said to be extremely valuable for interim testing during development as well as for final test or production line quality checks.

Variable-speed drive and 1/15 hp split-phase induction motor of the Model 14-28 are housed in a cast aluminum base. Linear sinusoidal motion is carried to a flex-mounted table via a connecting rod driven by a ball bearing mounted eccentric cam.

Frequency adjustment is infinitely variable between 10 and 55 cycles per second while the machine is running and frequencies down to 2 cps are available at extra cost. Amplitude setting from zero to 0.040 in. (double amplitude maximum is 0.080 in.) is provided by means of an eccentric adjustment. Literature available.

Circle No. 201 on Subscriber Service Card.

CANNON CONNECTORS

Two new connectors—a high speed, high altitude design and an AN quick-disconnect type—have been unveiled by Cannon Electric Co.

The former, a rack/panel pressurized connector, is intended for high-altitude and high vibration applications and features use of a special rubber seal about its insert faces upon mating.

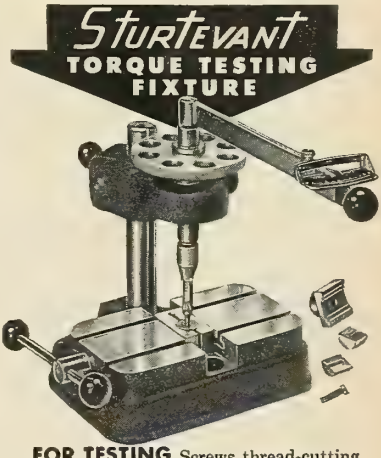
The quick-disconnect unit is basically an accessory made up of an adapter and coupler designed for standard AN connectors. Adapter is designed to screw over coupling threads of AN receptacle and contains an external locking groove which receives the formed ends of the coupler latch when fully engaged.

Cannon coupler is a special spring latching assembly designed to replace coupling nuts on standard AN3106 and AN3108B plugs.

Circle No. 215 on Subscriber Service Card.

FRACTIONAL HP MOTORS

New 400-cycle, 200 volt, three-phase, two-speed, constant torque motors introduced by Western Gear Corp. operate at speeds of 7,200 and 1,200 rpm and are available at ¼ hp and 1/24 hp respectively.



Western Gear's Model 1H58ML1 is "pancake" shaped, weighs 6.5 lbs. and measures 2½ in. deep by 3¾ in. in diameter. Output speeds are said to be plus or minus 5% with controlled acceleration and deceleration.

Circle No. 213 on Subscriber Service Card.

MINIATURE VIBRATOR

P. R. Mallory & Co., Inc. is marketing a new miniaturized vibrator that weighs only 1.5 oz. and measures 1¼ in. high by ¾ in. diameter. The Mallory 1900 series was developed for use in missile power supplies, primarily for guidance system applications.

New vibrator is rated for shock loads of 9,000 g's and above and is said to have performed satisfactorily after a shock exceeding 17,000 g's. It was not affected by spin test accelerations from

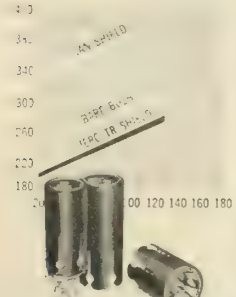
NOW—increase electron tube life *12 TIMES!



COMPARISON OF COOLING EFFECTIVENESS

Exclusive IERC Tube Cooling Effectiveness Provides Greatly Extended Tube Life And Reliability!

Though electronic engineers know that even the *slightest* tube temperature reduction improves tube life, the greatest success enjoyed in obtaining *extended* tube life has been when IERC Heat-dissipating Tube Shields have been specified and used. Results show that extensive gains in tube life and reliability are easily achieved—that tube operating temperatures are reduced as much as 150°C—that IERC's Military Type "B" shield is the *only effective answer* to obtain these benefits in *your* new equipment. Positive shock and vibration protection plus electrostatic shielding is provided. Graphs show temperature reductions when IERC "B" and "TR" shields are used with 6005 tube operating at full plate dissipation.

PATENTED OR PATS PEND. CROSS-LICENSED WITH NORTH AMERICAN AVIATION, INC.

Retrofit For Maximum Tube Life

No modification is required with IERC "TR" Type Heat-dissipating tube shields! TR's fit easily to existing JAN sockets—greatly extend tube life through excellent cooling and retention against shock and vibration.

standstill to 13,000 rpm, according to Mallory.

Designed for intermittent service, new vibrator is a 400 cycle, full-wave interrupter type that will deliver up to 20 watts for short periods.

Circle No. 217 on Subscriber Service Card.

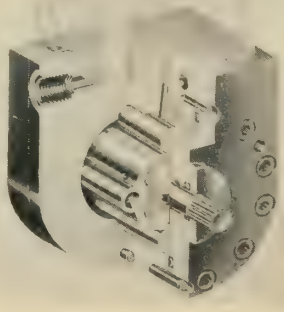
ARMING SOLENOID

An 11-ounce arming solenoid introduced by Stratos Division, Western Branch, is designed to arm missiles in high performance fighters, but can be adapted to other high-altitude applications according to its producer.

Unit operates unpressurized and, although qualified to 80,000 ft., has been tested successfully to 115,000 ft. Solenoid operates down to 18 volts and normal power drain is .7 amperes.

Circle No. 205 on Subscriber Service Card

MINIATURE PLUGS



Microdot, Inc. has unveiled two new miniature coaxial plugs, series 32-66 and 32-68, designed for use with Teflon RG-195U miniature coaxial cable having a maximum outside diameter of 0.155 in.

New plugs feature assembly without special tools and adaptability to use with existing Microdot S-93 receptacles. Series 32-66 plug has a guarded center pin.

Circle No. 219 on Subscriber Service Card.

ROTARY HYDRAULIC ACTUATOR

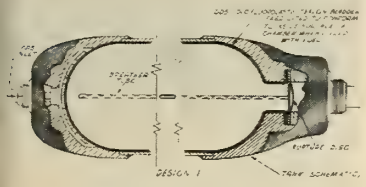
Aviation Division of Kelsey-Hayes Co. has unveiled a new rotary hydraulic actuator intended for use in precision control servo systems using fluid supply pressures in the 3,000 to 4,500 psi range.

New actuator ranges in size from 100 lb. in. to 6,000 lb. in. stall torque based on a 3,000-psi supply pressure rating. Static breakaway friction is said to be less than 6 lb. in.; internal leakage

50 x 10-6 in. 5/lb. sec. and total angular travel 125°. Actuator has a static breakaway friction of less than 1% maximum stall torque, according to K-H.

Circle No. 211 on Subscriber Service Card.

COOLANT PUMP



New lightweight coolant pump introduced by Applied Dynamics Corp. weighs about three pounds and is designed for such applications as coolant circulation in missile guidance systems.

The ADC pump, in a typical 3-pound model, measures 8 in. long and 3 in. diameter and operates from 400 cycle power source. Design feature is leakproof construction utilizing a "canned" motor that requires no seals or stuffing boxes. Available designs are of centrifugal or positive displacement types.

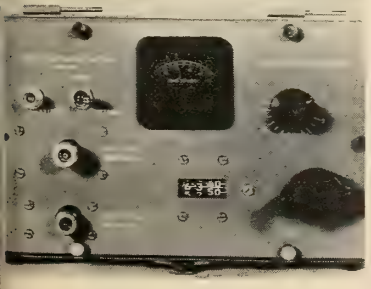
Circle No. 214 on Subscriber Service Card.

EXPULSION BLADDERS

Joclin Manufacturing Co. has announced development of fluorolastic Teflon seamless fuel bladders for handling fuels and oxidizers in missile propellant systems. Units are of the expulsion type in which gas is introduced at one end of cell to propel fuel from the other.

According to Joclin officials, the new container and fuel bladder combination is the result of two years of research to develop equipment that would cope with the 1,000-degree spread between —450° and 550° temperatures experienced in high altitude missile, ramjet, rocket engines.

Circle No. 206 on Subscriber Service Card



TEMPERATURE PROBE

Total temperature probe developed by Aero Research Instrument Co. for missile use is available with a choice of resistance thermistor of thermocouple sensing elements. Resistance elements are designed for operating ranges up to 1,000°F; thermocouple elements to 2,800°F. Probes are said to be completely insensitive to 20-degree angle of attack or yaw.

FOR *Vibration analysis*

THE TP-625 FREQUENCY ANALYZER

FEATURES

- LINEAR FREQUENCY CALIBRATION — Manual or Automatic Sweep
- EXCELLENT STABILITY — Temperature Controlled bridge-stabilized oscillator
- CONSTANT FREQUENCY BANDWIDTH — As narrow as 2 cps; as broad as 200 cps
- DYNAMIC RANGE — As great as 66 db (depending upon filter employed)
- SPECTRUM — 2 cps to 25,000 cps
- MULTICHANNEL ANALYSIS — Simultaneous analysis of numerous channels

The TP-625 Frequency Analyzer will determine the recorded frequency-amplitude spectrum of a random wave within the frequency range of 2 cps to 25,000 cps. In addition to analyzing random waves, the instrument will also determine the frequency and amplitude of the individual components in a periodic wave within this frequency range.

Wave components resulting from vibration, pressure, strain, light, etc., can be measured in decibels, in percent of total signal or both. Results are indicated on a calibrated attenuator and on a meter. For permanent, detailed analysis, high and low impedance output are provided to drive a recorder. When equipped with its accessory servo system, the TP-625 will follow RPM, or multiples of RPM, in engines throughout an operating range.

For specifications and further information, write for bulletin 625-1-956.

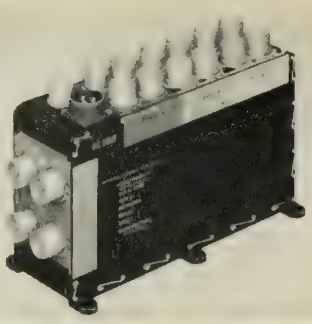
redesigned to give better accuracy and legibility. Principal change is the elimination of two micrometers and substitution of a Veeder-Root digital counter system for frequency readings.

Frequency in mc is obtained without calculations or written interpolation to a rated accuracy of 0.2%. Two tuned cavities are used. They are tuned by a precision lead screw. Both tuning shafts are driven by a single knob. Counter readings are referred to a universal nomograph-type calibration chart. The Narda Corp.

Circle No. 240 on Subscriber Service Card.

CONTROL VALVE



New 3-way air control valve introduced by M. C. Manufacturing Co. is designed for use with air or nitrogen, weighs only 0.28 lbs. and conforms to Spec. MIL-P-5518A and MIL-P-8564.

Valve is rated for operation at temperatures from —65° to 225°F and pressure of 3,000 psi. Internal leakage is said not to exceed one bubble in two minutes with 500 to 3,000 psi applied at pressure port.

Circle No. 200 on Subscriber Service Card.

ELECTRIC SUBSTATION

Miniature electric substation developed by Cole Electric Co. for the Northrop *Snark* missile is designed to transfer 88 electrical circuits and seven signal circuits from ground test power to airborne supply in 2½ seconds. Weighing only 28 lbs., the Cole system is remotely operated and provides instantaneous synchronization—make before break—to maintain a steady, constant power supply.

Substation draws 6.2 amperes at 28 volts for 2.5 seconds maximum. Current used totals 434 watt-seconds, instead of a continuous load as would be necessitated by a large group of relays, according to the manufacturer.

Circle No. 204 on Subscriber Service Card

TRACKING SYSTEM

New track-while-scan radar system developed by Westinghouse Electric Corp. electronic division automatically reports on 72 targets in three dimensions.

New system, is basically a hybrid digital-analog system in which error sensing is an analog function controlled by a digital computer. Latter computes, controls and displays data on all 72 tracks.

Construction features plug-in packaged unit design using printed circuits. All units are broken down into 200 lb pieces each with its individual transit case.

Circle No. 216 on Subscriber Service Card.

MISSILE RANGE RADAR

Radio Corp. of America has unveiled an instrumentation radar system company officials say for the first time permit direct calibration and immediate evaluation of missile performance.

The new radar, developed to join Navy Bureau of Aeronautics and Army Signal Corps specifications, is adaptable to plotting performance of satellite, drone

Electrofilm

HEATING ELEMENTS

ENGINEERED TO FIT YOUR DESIGN

INSPECTION PROBLEMS?

This booklet is for you!

This comprehensive, elaborately illustrated booklet provides practical information on the use of the famous A. C. M. I. Borescope in various industries, for the inspection of interior areas or surfaces not otherwise visible—together with full data on the types of Borescope available, and on their care and maintenance. Have you received your copy?

Free on request

Fill in and mail today

To American Cystoscope Makers, Inc.

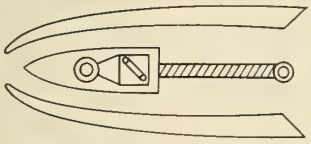
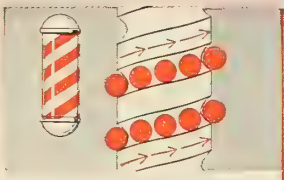
TOO "HOT" TO HANDLE

with ordinary actuators?

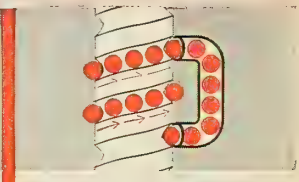


Saginaw b/b Screws and b/b Splines are dependably solving critical guidance and control problems for missile and rocket engineers . . .

TYPICAL APPLICATIONS



Control surface actuators



Nose cone positioners

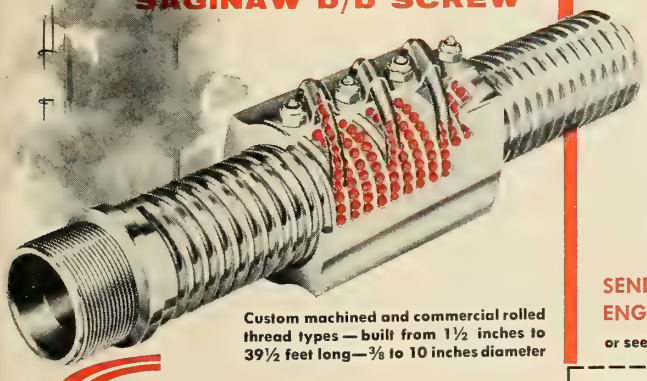
Evelon positioners • Afterburner controls • Speed brake actuators • Rocket engine displacement actuators • Clamping mechanisms for missile boosters • Fuel controls (3-dimensional cams) • Black box tuning devices—telemetering and guidance systems • Antenna coupler tuning mechanisms

Nut *glides* on steel balls. Like stripes on a barber pole, the balls travel toward end of nut through spiral "tunnel" formed by concave threads in both screw and mating nut.

At end of trip, one or more tubular guides lead balls diagonally back across outside of nut to starting point, forming closed circuit through which balls recirculate.

1 VITAL POWER SAVINGS. With guaranteed efficiency of 90%, Saginaw b/b Screws are up to 5 times as efficient as Acme screws, require only ⅙ as much torque. This permits much smaller motors with far less drain on the electrical system. Circuitry is greatly simplified.

2 SPACE/WEIGHT REDUCTION. Saginaw b/b Screws permit use of smaller motors and gear boxes; eliminate pumps, accumulators and piping required by hydraulics. In addition, Saginaw b/b Screws themselves are smaller and lighter. Units have been engineered from 1½ in. to 39½ ft. in length.

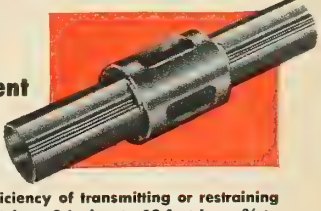


3 PRECISE POSITIONING. Machine-ground Saginaw b/b Screws offer a great advantage over hydraulics or pneumatics because a component can be positioned at a predetermined point with precision. Tolerances on position are held within .0006 in./ft. of travel.

4 TEMPERATURE TOLERANCE. Normal operating range is from −75° to +275° F., but assemblies have been designed in selected materials which function efficiently as high as +900° F. These units are practical where hydraulic fluids have lost efficiency or reached their flash point.

5 LUBRICATION LATITUDE. Even if lubrication fails or cannot originally be provided because of extreme temperatures or other problems, Saginaw b/b Screws will still operate with remarkable efficiency. Saginaw units have been designed, built and qualified for operation without any lubrication.

6 FAIL-SAFE PERFORMANCE. Far less vulnerable than hydraulics. In addition, Saginaw offers three significant advantages over other makes: (1) Gothic arch grooves eliminate dirt sensitivity, increase ball life; (2) yoke deflectors and (3) multiple circuits provide added assurance against operating failure.



SAGINAW b/b SCREW

Custom machined and commercial rolled thread types — built from 1½ inches to 39½ feet long—⅜ to 10 inches diameter

SAGINAW b/b SPLINE

Averages 40 times lower friction coefficient than sliding splines

Radically increases efficiency of transmitting or restraining high torque loads; built from 3 inches to 10 feet long, ⅜ to 6 inches diameter

A lightweight skin section 5 feet by 3 feet in compound contours. One side an airfoil, the other side a heat collection grid of maximum conductivity through the skin. A tolerance of .010" on mating surfaces.

This casting was produced by a unique foundry technique developed by the aluminum foundry of Morris Bean & Co. A rush schedule was met on prototypes, and the casting is now delivered in production quantities.

If you seek new approaches on difficult-to-form access doors, fins, airfoil sections, leading edges, or other problem shapes, you should become acquainted with—

MOTOR GENERATOR

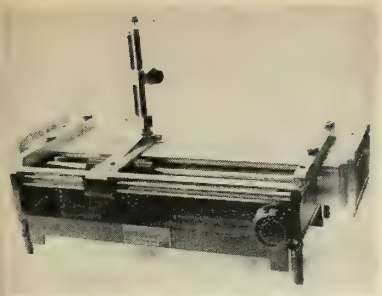
Production of a new size 10 ac motor generator for error rate damping in missile servo systems has been announced by Clifton Precision Products.

Weighing 72 grams, the Clifton unit requires an input power of 0.2 watts and has an output of 0.16 volts per 1000 rpm. No load speed is 7,000 rpm.

Circle No. 218 on Subscriber Service Card.

ROTARY ACTUATOR

A rotary actuator marketed by Electrical Engineering and Manufacturing Corp. has a travel of 45 degrees at .625 rpm. Operating on a 320 to 480 cycle ac frequency range (compared to MIL Spec. 380 to 420 cycles), the EEMCO D-822 actuator is said to eliminate the need for a constant speed drive in aircraft or missile power generation systems. Actuator operates under 26,000 in. lb. normal load with a maximum of 52,000 in. lbs.



Circle No. 202 on Subscriber Service Card.

SLOTTED LINE KIT

A carriage and slotted line sections are available for taking standing wave measurements in several of the larger waveguide sizes. Slotted sections for 1.7 to 4.9 kmc are available in five sizes. The carriage accommodates four interchangeable slotted sections in different waveguide sizes and slow carriage travel is permitted through vernier positioning of the probe.

The unit can be adapted for remote operation by using a motor drive and limit

switches. The carriage is designed to use most standard probes without alteration. The Diamond Antenna & Microwave Corp.

Circle No. 220 on Subscriber Service Card

LOW TEMPERATURE COUPLINGS

New line of quick couplings marketed by Hofman Laboratories for use in low temperature apparatus require only ¼ turn to open or close. Design employs a mechanical cam action to provide a metal-to-metal medium-pressure contact in place of gaskets for positive sealing.

Produced from high quality bronze, the Hofman couplings are available in 1 in. to 3 in. diameters at ½ in. increments, plus a larger 4 in. diameter model. Hofman also provides armored transfer hoses with couplings installed.

Circe No. 239 on Subscriber Service Card.

SHOCK MOUNTINGS

New series of light-weight shock mounting devices introduced by Shur-Lok Corp. are designed for use in electronics, radar and missile applications. New units include six types of electronic clamp assemblies, four of the hinged type. Another Shur-Lok device is a mating electronic equipment hook for vertical and horizontal attachment at a maximum angle of 92 degrees.

Circle No. 207 on Subscriber Service Card

INSTRUMENT TRANSLATOR

A transistorized instrument translator permits substitution of variable reluctance electro-mechanical pickoffs for potentiometers in missile systems without adding much weight and size.

The translator receives power from the system source, whether ac or dc, and when connected to a suitable ac sensing transducer produces an ac or dc signal proportional to the transducer sensed signals. Various models are available to operate motors, recorders, hydraulic valves, servo motors, etc. The unit is

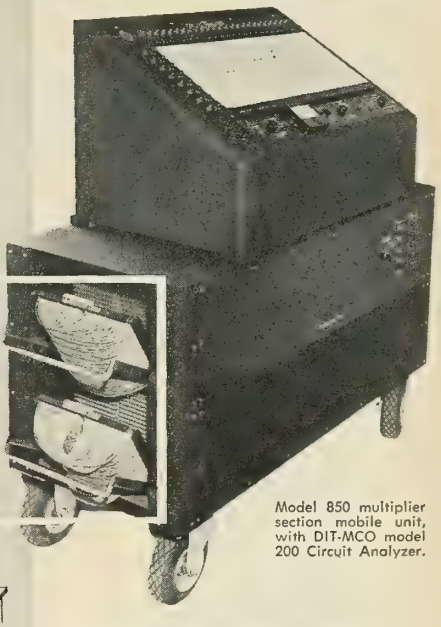
. . . another startling new development in automatic electrical system testing!



New Model 850

MULTIPLIER SECTION

featuring . . .

plugboard programming

new jumper-wire system simplifies test make-up and maintenance testing

Model 850 multiplier section mobile unit, with DIT-MCO model 200 Circuit Analyzer.

Now! In one operation at his desk, planner can design circuitry, layout matrix chart and jumper plugboard to conform to test sequence.

Now! Thorough, periodic maintenance tests can be made quickly and economically throughout the life of any airplane or missile.

Now! Test Modified Wiring Systems Without Altering Adapter Cables!

Do modified and improved electrical systems throw your testing section into a tailspin? Normally, it means existing test machinery (or the adapter cables, if DIT-MCO equipment is used) must be changed to conform to the circuit modifications. Here's how the new DIT-MCO plugboard system has solved that problem.

Circuitry can now be connected to the tester by the most convenient point-to-point method. Connecting wires (adapter cables) do not have to conform to any pattern. The testing sequence is programmed, quickly and easily, on the portable plugboards. Any subsequent circuit modifications are also handled on the plugboards . . . without changing existing adapter cables.

This is just one advantage offered by this new development. Write for full details on how DIT-MCO can help solve all your test problems.

Write today for complete information:

ENGINEERS:

DIT-MCO needs executive calibre sales and design engineers *right now!* Excellent opportunity with respected organization *on the move.* Work with key men in aircraft and missile industries. Write today!

ACCELEROMETER

Genisco, Inc. is marketing an improved Model GLH accelerometer for missile flight and fire control systems. Weighing from 2 to 2.5 lbs. depending on G rating, the potentiometer-type instrument is available in ranges from ±IG to ±80G, or up to ±30G with reduced damping. Operational life is said to exceed 3 million cycles. Dimensions: 3.40 x 2.40 x 3.12 in.

Circle No. 203 on Subscriber Service Card

LIGHTWEIGHT MOTORS

Lundy Manufacturing Co. has unveiled a series of lightweight, fractional horse-

power motors rated from 1/20th to 1/8th hp and weighing from 15 to 22.5 oz. Designed for 26-volt operation, the Lundy motors feature an electromechanical brake, integral radio noise filter and nearly flat brush pressure characteristics made possible by use of a new brush rig construction.

Circle No. 234 on Subscriber Service Card.

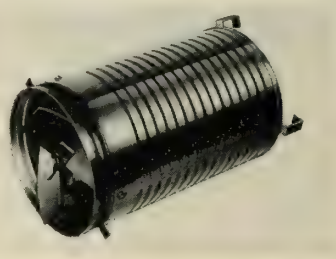
MANIFOLD VALVES

Robbins Aviation has developed an aluminum three-valve housing having five ports for use in air distribution boxes. It is adaptable to applications over a range extending from high vacuum to pressures of 3,500 psi.

Valve features finger-tip control for all pressures. Construction of manifold is such that any or all of its valves can be overhauled without disturbing the plumbing. Valves are company's standard type using plastic seats and O-rings for sealing.

Circle No. 235 on Subscriber Service Card.

HIGH TEMPERATURE MATERIALS



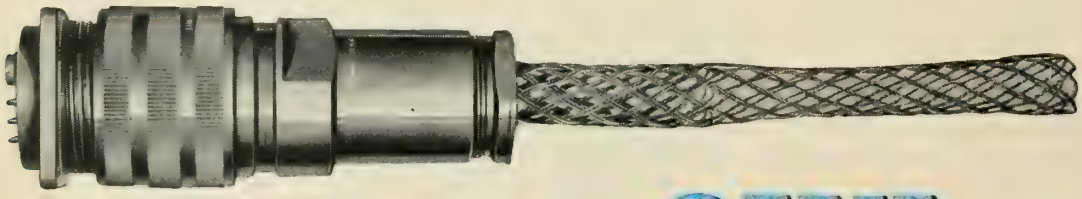
Haveg Industries, Inc. has introduced two new materials called Rocketon and Missileon for high temperature uses in rocket and missile construction. Basic make-up is a high melting silicate with an organic binder.

Among current uses cited by Haveg are: blast tubes for temperatures approaching 8,000°F; motor cases; flame reflectors and special insulating components. Company states that up to 17 parts in one rocket are of molded Rocketon.

Rocketon is said to have a compressive strength of 15,000 psi, tensile strength of 6,000 psi and ultimate shear of 9,500 psi. Respective figures for Missileon are 16,000; 6,000 and 10,500 psi. Density of both is 0.061 lbs. per cu. in.

Company states new compounds may be fabricated in parts as small as ½ in. dia. yet one-piece, field-fabricated sections have measured 205 ft. tall weighing 42,000 lbs.

Circle No. 236 on Subscriber Service Card.



POWER ABSORBER

An electric power absorber marketed by Sun Electric Corp. and used in Army's *Redstone* and Air Force's *Snark* missile programs is said to replace 21 500-watt stick resistors while occupying only 1/25th the space they normally would require.

The power absorber is essentially a small cylinder in which air is drawn through circumferential casing slots over specially-designed, V-section ribbon resistors.

Unit operates at 13,500 watts continuous duty and weighs 1 lb. per kw absorbed. Space requirements total ½ cu. ft.

Presenting the New QWL

Bendix ELECTRICAL CONNECTOR

A HEAVY-DUTY WATERPROOF POWER AND CONTROL CONNECTOR FOR USE WITH MULTI-CONDUCTOR CABLE

This new QWL Bendix* Electrical Connector was designed for and is being used principally on ground-launching equipment for missiles and ground radar equipment.

Obviously, for this important type of service only the highest standards of design and materials are acceptable.

That's why it will pay you to specify the Bendix QWL Electrical Connector for any job that requires exceptional performance over long periods of time.

QWL outstanding features:

1. It combines the strength advantages of machined bar stock aluminum with the shock-resistant qualities of a resilient insert.
2. A modified, double stub thread provides for speed and convenience in mating and disconnecting and the special tapered cross-section thread design resists loosening under vibration. The threads can be easily hand cleaned if contaminated by a substance such as mud or sand.
3. An Alumilite 225 hard anodic finish is used which gives a case hardening to the aluminum surface. This finish offers outstanding resistance to corrosion and abrasion.
4. The cable-compressing gland used within the cable accessory accomplishes both a firm anchoring of the cable and effective waterproofing for multi-conductor cables. Neoprene sealing gaskets are used at every joint to insure a watertight connector assembly.
5. The cable accessory is designed to accommodate a Kellems stainless steel wire strain relief grip for additional cable locking.
6. A left-hand thread is used on the cable accessory to prevent inadvertent loosening.
7. High-grade copper alloy contacts are used which provide for high current capacity and low voltage drop. The famous Bendix closed-entry socket is used for contacts sizes 12 and 16.

new product briefs

GREER HYDRAULICS, INC. has developed a linear actuator test stand said to achieve an accuracy within ± 1% in testing actuators at loads ranging from 50 to 5,000 lbs. Device is equipped to time actuator travel in inches per second and, by means of a dynamometer, to measure torque of screwjacks up to 60 lb. in.

Circle No. 225 on Subscribers Service Card.

EXPANDED LINE of flexible, polyethylene "Caplugs" for protection of ports or threaded fittings on delicate valves or instruments has been introduced by Protective Closures Co. Literature available.

Circle No. 226 on Subscribers Service Card.

CLAMP LINING for aircraft and missile installations introduced by Joclin Manufacturing Co. employs an asbestos wire-reinforced strip impregnated with Teflon. Joclamp lining operates at temperatures from —300° to 500°F and is said to resist damage from hydraulic fluids, oils and corrosive fuels.

Circle No. 227 on Subscribers Service Card.

RUSSELL MANUFACTURING CO. is producing an instrumentation tape woven with Fiberfrax, a new ceramic fiber developed by The Carborundum Co. Tape is wired to signal areas of high radioactivity when applied to atomic reactors and plumbing. Special zirconium adhesive used to affix tape is said to withstand temperatures up to 3,000°F.

Circle No. 228 on Subscribers Service Card.

TASK CORPORATION is marketing a new line of lightweight, high-performance induction motors for power outputs from 10 watts to 1,000 hp. Designs feature low weight to power ratios—a typical model weighing 4.8 lbs. is rated at 6½ hp at 24,000 rpm, 3-phase, 208 volts, 400 cycle.

Circle No. 229 on Subscribers Service Card.

ENVIRONMENTAL CHAMBER. A 5-cubic foot capacity environmental test chamber marketed by Mantec, Inc. is rated to drop temperatures from ambient to —65°F in five minutes and raise to 400°F in 10 minutes. Unit has 100 lb. dry ice capacity and is said to maintain temperature within —2°F over range from —100°F to 400°F. Overall dimensions are: length—22½ in., width—32 in. and depth—24 in.

Circle No. 230 on Subscribers Service Card.

SCINTILLA CONNECTOR. New SR type rack and panel electrical connector introduced by Scintilla Division, Bendix Aviation Corp. incorporates a solid shell and resilient insert to facilitate pressurization and provide maximum protection against vibration. They are rated for operation from—0° to 250°F.

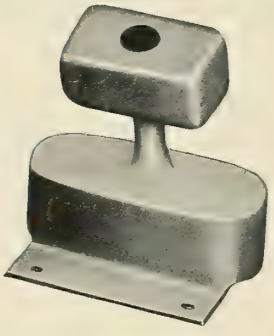
Circle No. 231 on Subscribers Service Card.

TEFLON ENCAPSULATED, color coded flat cable for aircraft and missile electronics has been introduced by Miljan, Inc. Wire sizes range from 16 to 26 gauge and cables are fabricated with any number of wires up to a maximum of two inches in width.

Circle No. 232 on Subscribers Service Card.

ENVIRONMENT RESISTANT electrical connectors announced by The Pyle-National Co. are said to be impervious to water, moisture, oil, pressure, vibration and shock. Connectors conform to Spec. MIL-C-5015B. Literature available.

Circle No. 233 on Subscribers Service Card.



Don't be grounded by your engineering problems!

The Investment Casting process offers unlimited freedom for the thousands of designs now on the aeronautical horizon. Intricate shapes, unusual contours, metals too difficult to form or machine need not be your problem.

ARWOOD has been serving aviation with quality investment castings for over a decade . . . maintaining its leadership by meeting design specifications, quality standards, delivery schedules and competitive prices.

Write today for your copy of "A Critical Survey of Investment Casting", written especially for design, production engineers.

CASE IN POINT!

FREEDOM OF DESIGN

This magnesium rudder component on a jet bomber consists of two hollow rectangular chambers joined by a tube. A wall thickness of 0.08" is uniformly maintained, proving that extensive areas of thin section and complex curvature can be investment cast without resort to joining.

FREEDOM OF ALLOY SELECTION

In order to increase the strength and creep resistance of this jet engine strut, the material specification was changed from stainless steel to a special low alloy steel. Investment casting offers this freedom in choice of alloy at little or no extra cost.

"PIONEERS IN INVESTMENT CASTING"

INDUSTRY SPOTLIGHT

By Joseph S. Murphy

Complex Computers For Missiles

The electronic computer, virtually an inseparable ingredient in the nation's missile and rocket program since its development, is shaping a new giant in U.S. industry.

This year, according to the Assn. for Computing Machinery, total computer sales and rentals will reach the $250 million mark. And this does not include the special purpose, one-of-a-kind variety of computer that is not commercially available for lease or sale.

ACM's forecast came during the recent Western Joint Computer Conference in Los Angeles. At that session, eight of the country's leading computer producers gave this round-up report on today's equipment, tomorrow's prospects:

International Business Machines Corps.—STRETCH computer, slated for Atomic Energy Commission projects and due for completion by 1960, will be about 30 to 40 times faster than present computers. It will multiply and add numbers at rates up to one million items per second.

Remington Rand Univac and Philco Corp.—Reviewed their respective development of "desk size" computers which use magnetic amplifiers and transistors instead of vacuum tubes. Units consume no more electricity than four 100-watt light bulbs, and although now intended for scientific applications, developments for commercial use are anticipated.

National Cash Register Co.—announced its extensively transistorized computer designed for such commercial use.

Datamatic Corp.—Stated its Datamatic 1000 computer will store nearly four billion decimal digits and transfer these in the computer at a rate of 60,000 per second.

Logistics Research, Inc.—Reported its Alwac 800 can store up to six million decimal digits and gain access to groups of 12 of these digits in 40 one-millionths of a second. First Alwac 800 is slated for Federal Reserve Board in Washington.

Radio Corp. of America—Described its Bizmac II as a large-scale business data processor fitted with many forms of memory devices and especially designed for maintenance of business files. It is a modified version of Bizmac I used by Army Ordnance for inventory control. Electro Data Division, Burroughs Corp. said the Datatron computer will permit storage of 200 million decimal digits. Its system has been programmed to maintain a 200,000 item file for inventory control operations.

One of the better examples of the missile industry's efforts to get the most out of present-day computer equipment is a "do-it-yourself" program recently announced by Lockheed's Missile Systems Division.

MSD has set up a special course to qualify employes on the use of its IBM 650 computers. After 12-hours instruction, they are turned loose to use the equipment to solve mathematical problems as they arise.

The training is given on company time and the only prerequisite to the instruction is a knowledge of algebra.

Lockheed feels this approach will ease the workload of professional programmers on the staff of E. K. Fisher, head of its mathematics and computer service department at the MSD Van Nuys, Calif. plant.

Key to the "do-it-yourself" computer approach, according to Lockheed, is the development by IBM of a new simplified coding technique called SOAP (symbolic optimum assembly programming).

This technique makes it possible for the novice to write actual equations on his coding sheet, instead of the complex system of address numbers normally used to locate information within the machine.

In the Lockheed system, the engineer will first state his problem as an equation, then draw up a flow chart or analysis of the problem as a series of computer equations. He fills out a coding sheet from which a computer key punch operator takes instructions.

Next, he checks answers against a test case, for which he knows the answer, to locate possible errors. As part of the instruction course, he is taught how to diagnose answers and trace errors should they turn up. ★

Lockheed Computer Chief E. K. FISHER instructs missile engineer, MRS. FLORINE CAIN, on workings of IBM 650 computer. After 12 hours training, Missile System Division engineers program their own problems as part of "do it yourself" computer approach.

GE Gets TV Contract For Patrick AFB

General Electric Co.'s Technical Products Dept. has received an Army Signal Supply Agency contract to produce a closed-circuit color TV system for observing and tracking missiles at Patrick AFB, Fla.

A GE spokesman said the system will be used by Army observers for close-up viewing of launching operations and for tracking up to a possible 100,000 ft. altitude. Use of color TV is designed to give engineers valuable data on flight characteristics by observation and analysis of rocket motor flame characteristics at takeoff.

The new system is scheduled for delivery in May. Although the dollar value of the contract was not disclosed, it is believed to approach the high end of the estimated $25,000 to $100,000 range of price tags prevailing for color TV system ranges.

R-W Acts to Speed Test Data on ICBM

The Ramo-Wooldridge Corp., technical strategist in the Air Force's Ballistic Missile Program, has set out to speed the analytical side of missile testing to keep pace with advances.

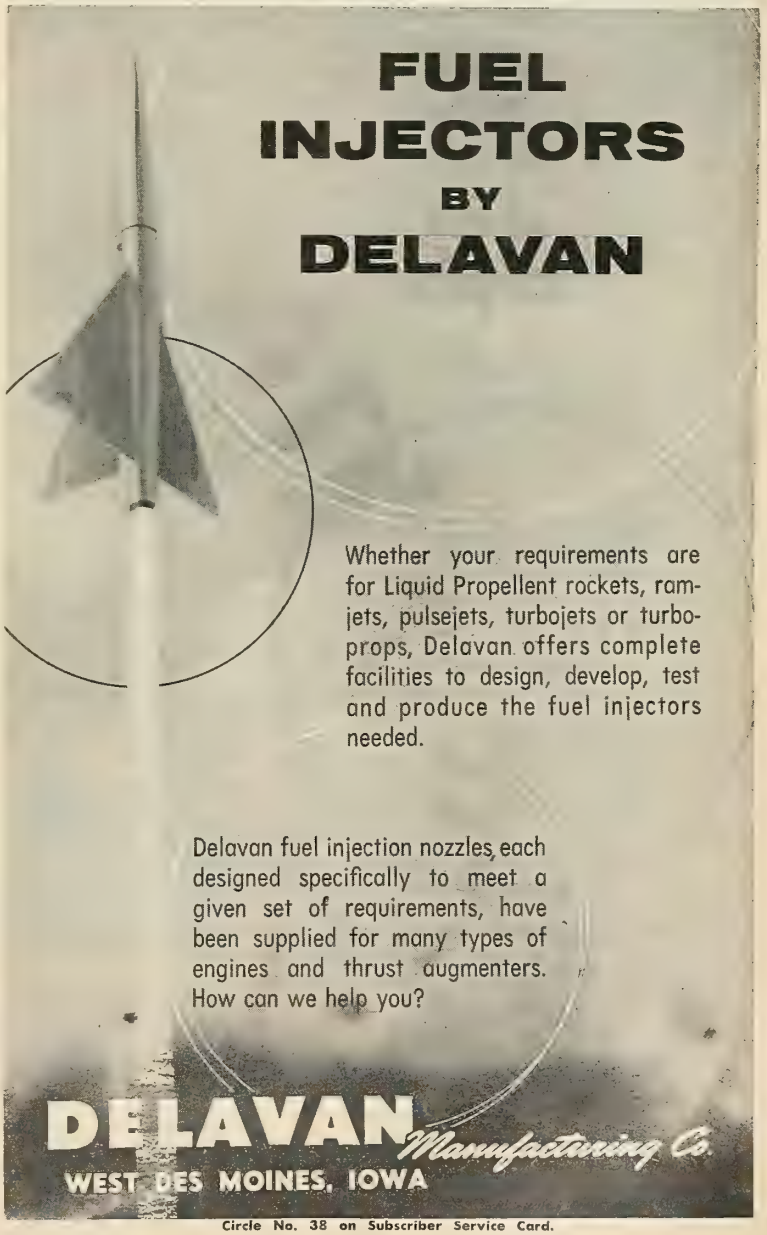
A new facility unveiled this month by Ramo-Wooldridge is designed to do just that. Its aims—quick and accurate reduction of telemetered test data; more rapid analysis.

The R-W installation designed and built by its Electronic Instrumentation Division, will be operated by its Guided Missile Research Division.

Emphasis throughout its development was keyed to flexibility, according to R-W officials. Equipment now installed in the data reduction center can be quickly interconnected into circuits which can reduce any of a variety of input signals into forms required for engineering analysis. Provision for addition of new equipment is "built-in" should improved techniques become available.

A wide selection of equipment in the center has been united for flexibility by routing all circuits through a central "patchboard" control panel. This permits engineers to pre-wire circuits that will link together all units needed to process a specific piece of missile test data.

Output equipment is equally as flexible. It can produce graphic records for study by engineers, magnetic tape recordings for analysis in the computing center, or can feed signals directly into vibration analysis equipment in the data reduction center.



Typical of the versatility of the entire installation is the variety of equipment in the vibration analysis section alone. It includes a Davies automatic wave analyzer, a Hewlett-Packard wave analyzer, a Kay vibralizer, a specially assembled half-octave filter bank plus a special correlation function computer developed by the R-W Electronics Research Lab.

All units are assembled in modules with space and power supply provided in the overall center for 50 modules. To date 31 positions are occupied.

In the plan for the future are the addition of other devices to speed missile test data into engineering answers. They include equipment for time coding and decoding, automatic data search, pulse code modulation telemetering decommutation, data linearizing, Doppler data processing and other specialized requirements.

Douglas Divisions to Share Thor Engineering Work

Douglas-Santa Monica Division has subcontracted a portion of engineering for the Air Force *Thor* intermediate range ballistic missile to Douglas-Long Beach Division. Project coordinator on Thor at Long Beach will be W. W. Miller.

NEW

Trans-Sonics*

"TAPE-ON" SURFACE TEMPERATURE RESISTORS for Temperature Telemetering

- NO THICKER THAN A PIECE OF TAPE
- OUTPUT UP TO 5 VOLTS WITHOUT AMPLIFICATION
- AVAILABLE IN VARIOUS RANGES FROM −300° to +400°F.
- RESISTANCE CHANGE OF 100 OHMS OVER SPECIFIED RANGE
- NO HOLES TO DRILL — QUICK AND EASY "TAPE-ON" INSTALLATION

Trans-Sonics Type 1371 "Tape-on" Surface Temperature Resistors are precision resistance thermometers with a platinum resistance winding as the sensing element. These resistors which are no thicker than a piece of tape may be applied to *any surface* whose temperatures are to be measured. In a commutation circuit, they modulate standard telemetering transmitters without amplification. The new Type 1371 "Tape-on" Surface Temperature Resistors may be added to an installation using other Trans-Sonics temperature transducers without any further circuit modification. Each resistor is furnished with 6" long fibreglas-covered constantan leads. Write for Bulletin 1371 to Trans-Sonics, Inc., Dept. 9.

industry briefs

REACTION MOTORS, INC. paid 74% of its vendor/subcontractor dollar volume to 1,500 small business firms during last six months of 1956. Payments to small business totaled $3,082,000 of overall $4,182,000 spent by RMI.

FINN AERONAUTICAL DIVISION, Hawthorne, N. J. producer of combustion liners and flameholders of *Navaho* missile's Curtiss-Wright ramjet engines, has doubled facilities to 20,000 sq. ft.

MICRODOT, INC., builder of microminiature coaxial cables and connectors, has moved to new quarters at 220 Pasadena Ave., So. Pasadena, Calif.

SOLAR AIRCRAFT CO., San Diego, has received a $2 million contract from Hughes Aircraft Co. to produce *Falcon* missile airframes.

TUCSON INSTRUMENT CORP., new aircraft and missile electronics firm located in Tucson, Ariz. has commenced manufacture of potentiometers and electronic test equipment. President and treasurer is F. R. Perier.

G. M. GIANNINI & CO., INC. reports 1956 sales of $9,510,091, up 47% from $6,436,330 in 1955. Net earnings were $339,521 against $290,787 in 1955.

REACTION MOTORS, INC. has shifted its Los Angeles offices to larger quarters at 10835 Santa Monica Blvd. Office provides joint representation for RMI and Olin Mathieson Chemical Corp. and is headed by J. M. Rogers.

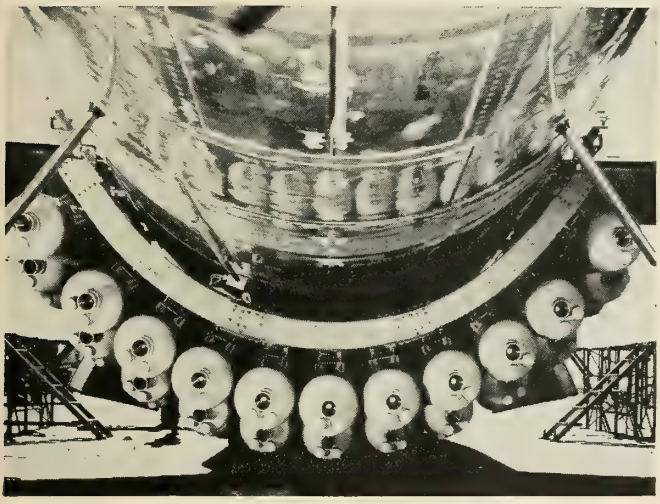
RHEEM MANUFACTURING CO. has commenced operations in an enlarged electronics research laboratory and production facility at 7777 Industry Ave., Riveria, Calif.

SPERRY RAND CORP. will build a $2 million plant at Clearwater, Fla., to specialize in research in microwave physics and the development of advanced radar and missile instrumentation. New division will be headed by E. J. Venaglia and will commence operations with a staff of 150 scientists and technicians.

BELL AIRCRAFT CORP. has received a $405,000 facilities contract from Air Materiel Command in its GAM-63 *Rascal* missile program.

GILFILLAN BROS., Los Angeles, has received a $2,877,000 contract to conduct a design improvement study of the ground guidance system for Army's Firestone *Corporal* missile.

GOODYEAR AIRCRAFT CORP. plans construction of a 20,000 sq. ft. addition to its rocket component production and development facilities at Akron.



THE FIRESTONE TIRE & RUBBER CO., Los Angeles, has been awarded a $1,756,846 contract to design and build a guided missile stowage and launching system.

KAMAN AIRCRAFT CORP. is forming a Nuclear Division to engage in systems analysis and research in the fields of nuclear ordnance and propulsion. Group will be located at Albuquerque, N.M. under v.p. and general manager, Dr. K. W. Erickson, former chief of experimental weapons research for Sandia Corp.

THE EDO CORP. has received a $2,188,200 Navy Bureau of Aeronautics contract to build an undisclosed number of missile launchers and pylons.

Advantages you get with Phillips 66

SOLID ROCKET PROPELLANTS

The M15 JATO loaded on Boeing B-47 The first of its kind to meet rigid Air Force performance tests. (Boeing Airplane Company photo)

At the Phillips operated Air Force Plant 66 near McGregor, Texas, there are extensive facilities for development, testing, and manufacture of rocket propellants. Consult Phillips highly competent scientists and engineers about your specific propulsion problems.

- *LOW COST.* Phillips family of solid propellants for rockets is made from readily available petrochemical materials, such as ammonium nitrate, synthetic rubber, and carbon black.

- *VERSATILE IN APPLICATION.* Phillips family of rockets is easily modified to meet various needs.

- *WIDE TEMPERATURE RANGE.* These rockets operate successfully from –75 F to 170 F.

- *INSENSITIVE TO DETONATION* by impact or explosion. Exhaust gases are noncorrosive and relatively low in temperature.

- *STORAGE.* Phillips 66 propellants can be stored for long periods of time without deteriorating.

Industry Highlights

By Fred S. Hunter

Interesting figures—The Douglas Aircraft Co.'s annual report shows missile sales in 1956 amounted to $140 million, and adds that orders for missiles and related equipment comprised approximately 16% of its backlog at the start of fiscal 1957. This translates into something above $170 million since Douglas reported a total backlog of $2,209 million and explained this was divided almost equally between military and commercial business. The Air Force recently revealed $67 million as the amount of current *Thor* ICBM contracts, leaving something in excess of $100 million in other missile work at Douglas.

•

More interesting figures—Lockheed Aircraft Corp. reports annual sales rate of its Missile Systems division now betters $70 million, and then goes on to stagger the imagination a bit by pointing out this is 13% greater than that of the entire air industry 20 years ago. In two years time, Lockheed's missile division multiplied its sales seven times, quadrupled its work force (now approximately 5,000) and more than doubled plant area in use or under construction (almost one million square feet.)

•

Still more interesting figures—J. R. Dempsey, general manager of Convair-Astronautics, quotes numbers to show missiles make more jobs. For the ICBM *Atlas*, Convair-Astronautics is scheduling employment of 8,000 workers. These will require 18,000 more in support work. For an airframe program of comparable scope, 8,000 direct wage earners would require only 11,000 more in supporting jobs. Astronautics, last year, spent more than $10 million with 330 suppliers in the San Diego area and $30 million with 894 suppliers in the Los Angeles area. They'll get more this year.

•

Not everyone seems to have been aware North American Aviation's Air Force contract for development of the *Navaho* was a three-stage affair. First stage was the turbojet X-10 test vehicle. Second stage was the intermediate XSM-64, with ramjet engines and a booster. Third stage is the long-range XSM-64A. The recent contract termination involved the intermediate stage XSM-64, with remaining funds and materials from this project transferred to the long-range XSM-64A, which continues with 1957 funds. Speculation over ultimate fate of the missile centers around the fact no money was earmarked for it in fiscal 1958 funds. But most people think 1958 money will still be budgeted for continuation of the project, so don't be in a hurry to write it off.

•

"Premium apparatus!" That's Lee Atwood's term for the electronics equipment the Autonetics division of North American is producing. A sample—the new CP-226 all-transistor digital computer, which weighs only 200 pounds and measures a mere six cubic feet, but will do everything, we're told, that an IBM 701 will do, only slower. Cost of the new machine is approximately $100,000. Autonetics envisions market possibilities for 3,000.

•

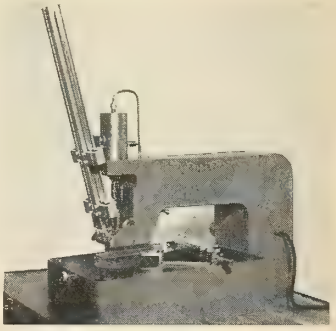
Berkeley division of Beckman Instruments, counting up, found 77 companies in the analog computor field in which it is active. Not all are turning out complete systems. Some make only components. But they have to be considered as possible competitors any time a request for bids is tossed out. Biggest analog plum up for grabs recently was a one-and-a-quarter-million-dollar job for the Glenn L. Martin Co.

This scientific pioneer is Dr. G. K. Wehner, designer of the space chamber which he uses here to determine the "sputtering" or disintegration rate of molybdenum under bombardment from atoms moving at 25,000 m.p.h., 200 miles above the earth.

What happens to metals at 25,000 m.p.h. 200 miles up?

General Mills scientists are finding some of the answers to this question, which bears directly on space ships and man-made satellites.

Their findings indicate that materials to be sent into space must possess properties not found in today's ores and alloys. Since few new metals remain to be discovered, they conclude that present ones must be given new properties to cope with the heat barrier and to keep vehicles from disintegrating under particle bombardment.



The study of metals in space flight represents but a single phase of General Mills' over-all program of advanced exploration in theoretical and developmental physics.

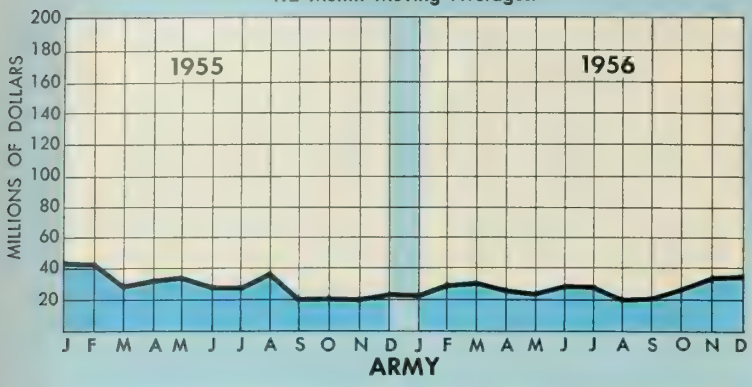
Findings in this "research for tomorrow" are being translated regularly into practical applications for industrial and military use today. If you have product or production problems, you can profit from these applications, and from our high-level production facilities.

Send for Production Facts

This interesting booklet tells the story of how you profit by giving us your difficult production problems. Write Mechanical Division, Dept. MR4, General Mills, 1620 Central Ave. N. E., Minneapolis, Minn.

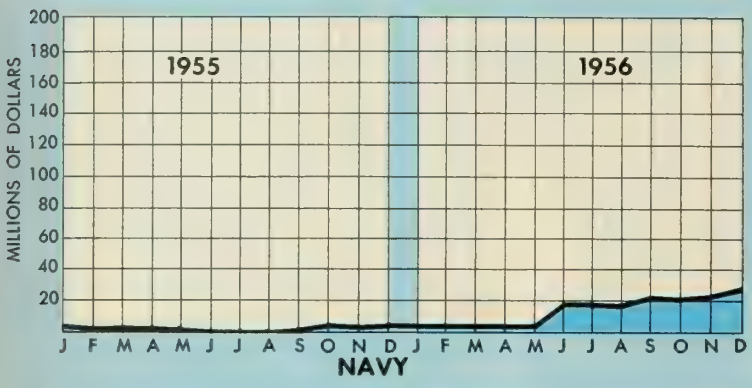
AUTOFAB: ***built for the present***

From General Mills' creative research and precision manufacturing come machines for industry to use today—machines such as *Autofab*, for near-automatic assembly of electronic components on printed circuit boards.



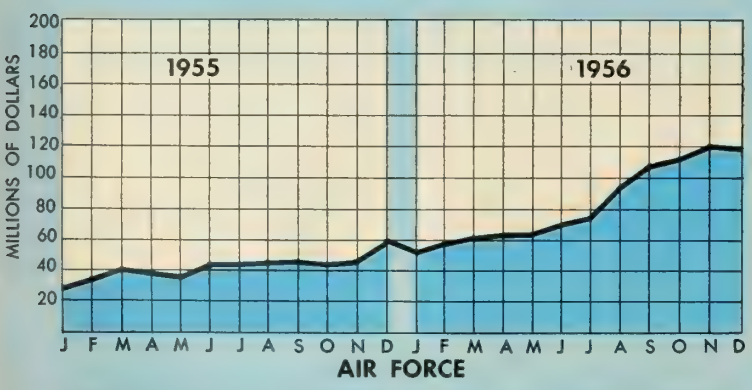
MECHANICAL DIVISION OF General Mills

CREATIVE RESEARCH AND DEVELOPMENT + PRECISION ENGINEERING AND PRODUCTION

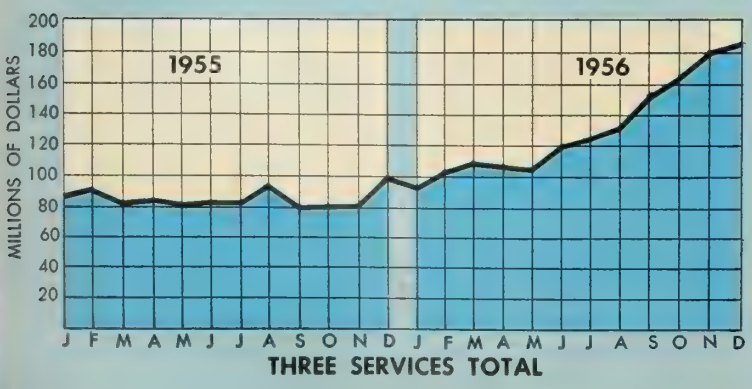


INDUSTRY BAROMETER

GUIDED MISSILE OBLIGATIONS INCURRED



(12 Month Moving Averages)



ARMY

NAVY

AIR FORCE

THREE SERVICES TOTAL

The twelve-month moving averages illustrated (see November 1956 "Industry Barometer") point out the rising rate of obligations for guided missiles during the current fiscal year.

Department of Defense average missile obligations have increased from $100,554,000 in December 1955 to $186,137,000 in December 1956, a jump of 85%.

Army guided missile obligations continue to fluctuate from month to month, but show a marked increase during November and December of 1956. The December '56 average obligations incurred ($36,251,000) represent an increase of 48% over December 1955 ($24,476,000).

Missile obligations incurred by the Navy reached a new high in December of '56 ($29,412,000). This figure is a 90% increase over December 1955 average obligations of $15,470,000.

The Air Force's average obligations show an upward trend during the first half of fiscal year 1957. December 1956 obligations ($119,940,000) increased 98% over December 1955 ($60,609,000).

Guided missile obligations incurred during the first half of fiscal year 1957 (July through December 1956) amounted to more than twice the money obligated for missiles by the Department of Defense during the first half of fiscal '56. From July through December $1,391 million were obligated, compared with $604 million in the previous year.

Direct obligations by the Department of Defense should average about $280 millions per month of the last six months of the current fiscal year (January-June 1957). This is based on the fact that total direct obligations for missiles are estimated at $3,071 million for fiscal year 1957. During the second half of FY 1957—based on current Pentagon thinking and money committed in the first half of the fiscal year, indications point to:

. . . Army missile obligations exceeding those of the first half, probably averaging about $83 million per month;

. . . Navy guided missile obligations decreasing over the first six months of fiscal '57, to an estimated $31 million per month for the six month period;

. . . Air Force obligations increasing; an average for the six month period of $166 million per month.

IBM Reports Income and Facilities Expansions

Year end report of the International Business Machines Corp. shows gross income as $734,339,780 compared to $563,548,792 for 1955. Net income after taxes was $68,784,510 which amounts to $13.10 on outstanding shares.

During the year, IBM said, the five-hundredth type 650 data processing machine, and the one-hundredth 700 series data processing machines were delivered to customers.

Facilities expansions noted were the new Kingston, N. Y. manufacturing plant for producing Sage computers, a 406,000 square foot plant and laboratory near Owego, N. Y., believed to be planned for production of Air Force BRANE navigation and bombing systems, and 96,000 more square feet of laboratory space at Poughkeepsie. N. Y.

Other new plans call for an engineering laboratory with 160,000 square feet in Kingston for work on SAGE and other defense projects.

A major new product that came out of the laboratories during the year was IBM's 305 RAMAC based on a new concept of random access accounting. Disc memory units can store 24 million digits of information.

Work is also underway on a large-scale computer being developed jointly by IBM and Los Alamos Scientific Laboratory of the AEC. The new computer will be between 100 and 200 times faster than any commercial computer in existence.

New Matador Contract

Air Materiel Command has awarded The Martin Co. a follow-on contract amounting to $1,527,981 for *Matador* TM-61B missile testing.

Talco is Building New Phoenix Facility

The Talco Engineering Co. of Hamden, Conn. has acquired a 2,000-acre plot near Phoenix, Ariz. for construction of testing and firing range facilities capable of handling cartridge-actuated and rocket devices.

F. G. Talley, Talco president, said the facilities also will be made available for evaluation of contractor-furnished and developed airborne equipment and systems.

Company plans to complete the

Research Scientists

At the AVCO *Research Laboratory* a young, creative scientist can find satisfaction in a small (200), youthful (average age 32), progressive laboratory which is moving rapidly along in the modern, scientific world.

Integrated here in a university-type atmosphere are the fields of physics, aerodynamics, and physical chemistry. You derive individual satisfaction working in these broad areas of knowledge in intimate contact with a top-notch scientific group. You receive individual recognition for your contribution to a new understanding of scientific fundamentals through publication of research results in the standard journals.

The *Research Laboratory* is engaged in the study of gases and gas dynamics at high temperatures. We are interested in the phenomena accompanying the dissociation and ionization of gases and in the application of these phenomena. Future plans call for research in non-competitive fields for application to defense and commercial products.

If you are interested in genuine research activity and have related research experience, you will be interested in these opportunities:

Jr. Scientists — Degree in Physics or Aerodynamics, plus 0-2 years experience.

Associate Scientists — Degree in Aerodynamics, plus 3-5 years experience.

To inquire about opportunities in the Research Laboratory, write or send resume to Robert M. Hale, Scientific and Professional Staff Appointments, Group 33.

first phase of construction in July including a sled track, environmental testing laboratory, office, shop and storage buildings. Firm's operations in Connecticut will continue at an expanded level with the Phoenix site slated to handle qualification and production testing of the larger equipment it builds.

Among the latter is a new personnel rocket catapult developed for the Convair F-102 and TF-102. Company officials said development of versions of this system for other aircraft is currently in progress.

General Tire Nets $10.8 Million

General Tire & Rubber Co. netted $10,860,129 in 1956, a drop from $11,600,463 in 1955 despite a sharp increase in sales from $295,731,096 to $390,471,772 for the parent firm and its subsidiaries, including Aerojet-General Corp.

Although specific Aerojet sales for the year were not given in General's annual report, it was noted that they increased by 109% over 1955 and that its backlog now exceeds $500 million.

The report did, however, deal in considerable detail with the accomplishments of Aerojet during the year, highlighting these specific points:

Manufacture of more than 1,300 large solid-propellant booster rockets for guided missiles.

Production of 40,000 smokeless JATO units, 1,000 *Sparrow* missile powerplants, 3,500 *Nike* sustainer motors and several hundred large JATO units for medium bombers.

Development of a liquid propellant booster for the Boeing *Bomarc*, followed by successful *Bomarc* testing at Patrick AFB, Fla.

General Tire also noted progress on development of a solid propellant sustainer motor for the Martin *Bullpup* missile; a booster for launching the Chance Vought *Regulus* II; and, start of work on a new *Sparrow* engine using Aerothane as propellant for increased specific impulse.

In the R&D area, Aerojet developed the largest solid propellant powerplant ever used in any ballistic missile, the report disclosed. The unit was developed for the Army's Jupiter IRBM and, in October, testing began on a reduced-scale Jupiter rocket.

Also mentioned in brief was Aerojet's activity toward development of a new type of powerplant, an air-turbo-rocket. The engine was described as a high-speed, high-altitude powerplant combining the best features of rockets and ramjets.

An Announcement

OF FIRST IMPORTANCE TO EXPERIENCED ROCKET ENGINEERS AND SCIENTISTS

- *Reaction Motors initiating big new Research and Development Program*
- *Key spots offered to men who have already made a name for themselves in Rockets*

If you're one of the relatively few trained rocket men in America, your experience will pay off handsomely at Reaction Motors. The first rocket company in America, RMI is now entering its period of greatest expansion, a period that will see far-reaching developments in America's fastest-growing industry. Your participation in RMI's program during this crucial period is your best guarantee of leadership in the industry. In a job like one of those listed below you'll be strategically placed for both achievement and advancement.

1. Stress Engineer

Degree in engineering or applied mechanics. Required experience in mechanical design with emphasis on stress analysis: 3 years for an engineer, to 6 years for the senior engineer. Must be able to handle and/or supervise involved analyses—including the effects of dynamic forces, high temperature gradients and high pressure differentials—under conditions where light weight is vital.

2. Technical Planning Engineer (advance design)

Our technical planning group has an immediate opening for a qualified engineer with about 5 years' experience (mostly mechanical) in high-performance turborocket engine design. Experience with turborockets should be broad and should cover thrust chambers and turbopumps. Additional experience with turbojet engines is also desired, though not essential. Work will involve, determining future propulsion requirements, evaluating them, and creating designs for products to meet them.

3. Controls Engineers

Here, we are looking for men who will solve rocket propulsion problems by applying their knowledge of fluid flow theory, thermodynamics, servomechanism and information theory, analog simulation or statistical design techniques—The work includes designing valves and other control components; development of hydraulic, pneumatic and electrical feedback control systems and sequence control systems; analog simulation of single components and complete systems, including computer set-up and problem formulation; application of statistical design techniques to control situations.

4. Applications Engineer

Work involves technical liaison with military agencies and airframe industry to discuss requirements and determine applications for aircraft pumps, valves, ignition systems and related products. Must have sufficient technical experience to understand construction, operation and performance of power plants and be able to integrate with requirements of airframe engineers. Knowledge of military contracts and airframe industry desirable. This is a responsible opportunity in the aviation industry for a mature, ambitious man to age 45 who possesses imagination, initiative and ability to organize.

RMI'S 6 MAIN PROJECT AREAS INCLUDE:

MISSILES • PILOTED AIRCRAFT • LAUNCHING DEVICES • GROUND SUPPORT EQUIPMENT • LIQUID AND SOLID PROPELLANT CHEMISTRY • NUCLEAR ROCKETS

For additional information on these or any other positions, drop a note or send complete resume in strict confidence to:

The Career of Tomorrow Can Be Yours... **TODAY!**

You and Your Family Should Read This Exciting New Brochure on Tomorrow's Brightest Engineering Activities!

Add NEW DIMENSIONS to your professional life . . .

A position with Westinghouse-Baltimore will add new dimensions to your engineering work in a number of ways. You will be a member of an engineering team pioneering advanced developments in the electronics field far beyond the state of the art. And, as an active participant in these pioneering ventures, you will find your creative and imaginative skills taxed to their utmost. You will grow as an individual through your contacts with some of the outstanding engineers and scientists of our day. And, you will be given every opportunity to continue your education and to take an active part in professional activities designed to further your career.

Add NEW DIMENSIONS to your family life . . .

More and more engineers are finding that a satisfying career can only be built around a full, rich family life. That is why Westinghouse-Baltimore stresses the advantages to the young engineer of coming to Baltimore. In the colorful new book, "New Dimensions," your family can get all the facts on this friendly city—its homes, schools, churches, social and cultural activities and its recreational facilities.

FOR YOUR COPY OF NEW DIMENSIONS:

Write to Dr. J. A. Medwin, Dept. 644

Westinghouse – BALTIMORE

An Engineer's Company

Advanced Electronics Systems, Ordnance, X-Ray, Carrier Microwave, and Induction Heating Equipment for Military, Industrial, and Commercial Purposes.

SINCE 1886

GE Dedicates IBM-704 Facility

First computer installation of its kind has been inaugurated by the General Electric Co.'s Computer Department on the Campus of Arizona State College.

The center is equipped with an International Business Machines Corp. 704 computer that will be jointly used by GE and the College.

H. R. Oldfield, general manager of GE's computer department predicted at the opening ceremonies that present computer sales of $450 million annually would rise to over $1 billion by 1966.

Martin To Expand Denver Facility

Recently completed $10-million plant of The Martin Co. in Denver will undergo further expansion at a cost of $2 million. Plan calls for addition of an engineering laboratory, extension of the administration building and of the plant cafeteria.

Martin now employs 2,500 at the facility and expects this figure to double in 1958.

Ryan Sales Increase, Net Drops in 1956

Ryan Aeronautical Co., producer of the Firebee jet-powered target drone, showed a 19% decrease in net profit last year despite an increase from $41,527,770 to $46,998,925 in sales for fiscal year ended October 31.

Declining profit was attributed to high "make-ready" costs in early phases of new items production.

Ryan backlog, however, increased $17 million and now stands at $92 million. In addition to the Firebee production, president T. Claude Ryan cited missile guidance as one of three phases of aviation electronics work being carried forward by the company.

Boeing Gets New Plant For *Bomarc* Manufacture

Boeing Airplane Co. will take over a former Army Corps of Engineers plant for *Bomarc* missile and B-52 bomber production under a recent Army-USAF agreement.

Some 100,000 sq. ft. of the new plant will be used for Bomarc work along with 200,000 sq. ft. of its new Development Center now in the construction stage. Balance of the 347,000 sq. ft. Army plant will be allocated to B-52 manufacturing and will be fitted with eight spar and two skin mills.

Convair Astronautics Move to Begin in June

Convair Astronautics Division expects to begin shifting personnel into its new $40 million Kearny Mesa plant late in June. First building up will be the engineering laboratory.

Plan is to transfer employes as space and facilities become available, with the overall shift extending from June through December.

In July, Convair will partially occupy two office buildings, one for engineering and the other administration. Cafeteria, power and security buildings will also be completed about the same time.

Last building slated for occupancy will be the manufacturing plant expected to be completed in November.

Missile Sales Up At Lockheed

Missile Systems Division of Lockheed Aircraft Corp., in the two years since its formation, has increased its sales seven-fold, quadrupled its work force and more than doubled its laboratory, office and production space, according to Lockheed president Robert E. Gross.

Gross places present sales at about a $70-million annual rate. MSD now has 1,000,000 sq. ft. at facilities in Van Nuys, Palo Alto and Sunnyvale, Calif. and has started construction of a 3,200-acre test center in the Santa Cruz mountains.

Two Contracts Let For New Fuels Plant

Air Force and Navy last month awarded contracts totaling $71.5 million for construction of facilities to produce high energy fuels.

AF contract, issued by Air Materiel Command, went to Olin Mathieson Chemical Co. in the amount of $33.5 million for a plant to be located at Niagara Falls, N. Y.

Navy's award to Callery Chemical Co. is further advanced than that of USAF. Ground was broken early last month on a $38-million facility at Muskogee, Okla. and output of HiCal, a boron compounded high-energy fuel, is expected late next year.

Bomarc Contract In The Making

The Air Force and Boeing began negotiations early last month for the first volume production contract for the IM-99 *Bomarc* pilotless interceptor missile. Weapon will be manufactured principally in Seattle with support from

engineers

ARMA *now developing*

inertial navigation system

for newest **ICBM TITAN**

ASSIGNMENT: create a guidance system for the Air Force's Intercontinental Ballistic Missile "TITAN"— a system with these never-before-achieved capabilities:

...able to operate anywhere, at any time, in any weather, at any altitude

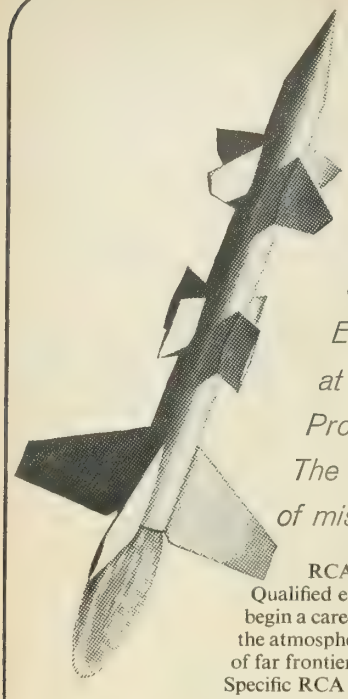
...able to withstand tremendous environmental conditions

...require no previous reconnaissance, radiate no signals for enemy to detect, reach target accurately

This is a task of great magnitude...best answered in ARMA'S opinion by applying the most advanced concept in guidance— INERTIAL NAVIGATION. This is a truly self-contained system, requiring no radio, magnetic or other contact with the earth or any other planet.

High creative calibre is required to develop the extraordinarily precise, miniaturized components Inertial Navigation demands— these include gyros, accelerometers, integrators and computers. ARMA'S selection for this urgent project was largely based on its outstanding accomplishments in the field of precision instruments and systems for navigation and fire control.

There is significant scientific progress to be achieved at this leadership company and individual renown to be won by engineers who join us now. Many supplementary benefits make an ARMA career doubly attractive. Moving allowances arranged.



Immediate openings for Senior Engineers, Engineers, and Associate Engineers, experienced in:

PRODUCT ENGINEERING
SYSTEMS EVALUATION
GYROSCOPICS
DIGITAL COMPUTERS
ACCELEROMETERS
TELEMETRY
GUIDANCE SYSTEMS
PRODUCTION TEST EQUIPMENT
PROJECT ENGINEERING
STABILIZING DEVICES
AUTOMATIC CONTROLS
ENVIRONMENTAL RESEARCH
GROUND SUPPORT EQUIPMENT
ENGINEERING STANDARDS
PROJECT ADMINISTRATION
COMPONENTS DEVELOPMENT
RELIABILITY
FIELD EVALUATION
DATA REDUCTION
DATA ANALYSIS

Please forward confidential resume. No reference contact without your permission.

ARMA

TECHNICAL PERSONNEL DEPARTMENT M-674
DIVISION OF AMERICAN BOSCH ARMA CORPORATION
Roosevelt Field, Garden City, Long Island, N. Y.

ELECTRONIC ENGINEERS...

become one of the first staff members of RCA's new ENGINEERING OPERATION at WHITE SANDS Proving Ground. The very nerve center of missile electronics!

RCA is new to White Sands! Qualified electronic engineers can now begin a career in a responsible position where the atmosphere crackles with the stimulation of far frontiers in missile electronics. Specific RCA assignments are in missile electronics, ground support systems, missile guidance and complex launching systems. You must, of course, have your EE, ME or physics degree, several years' electronic design experience . . . and must be familiar with one of these fields:

System and sub-system analysis
Reliability data control
Evaluation of new components
Internal instrumentation
Equipment control
Data analysis

Projects will relate to sub-systems such as:

PRECISION RADARS
DIGITAL DEVICES
ANALOG DEVICES
DATA PROCESSING EQUIPMENT
FIRE CONTROL
DATA SIMULATION

Start at an excellent salary . . . A full program of liberal benefits gives your income added security. RCA's Tuition Refund Plan will provide for advanced studies. RCA pays relocation expenses.

ARRANGE CONFIDENTIAL INTERVIEW WITH ENGINEERING MANAGEMENT

DEFENSE ELECTRONIC PRODUCTS

Wichita. Boeing will utilize 100,000 square feet of an Army Corps of Engineers facility in the Seattle area for *Bomarc* work. The government-owned facility was made available by the Air Force after working out an agreement with the Army.

Hughes Adopts Work-Study Plan

Hughes Aircraft Co. has launched an engineer work-study program with three universities designed to provide full payment of college tuition and related expenses for undergraduate engineers it employs.

Hughes officials said the plan is expected to increase to 950 the number of part-time or full-time employes studying for degrees at company expense. The new plan extends the program outside of the company for the first time.

Schools associated with the program are Loyola Univ. of Los Angeles; Univ. of Southern California and Univ. of California at Los Angeles.

Temco Names Plant For Missile Work

Temco Aircraft Corp., known recipient of a Navy contract to design and develop the *Corvus* missile, has designated its Garland, Tex. plant for missile and drone production.

Before the *Corvus* award, Temco won a Navy competition to build the XKDT-1 rocket-powered missile target drone.

ACF-Erco To Build Missile Arming Units

Contracts for design and development of safety and arming devices for Air Force's Boeing *Bomarc* and Army's Chrysler *Redstone* missiles have been awarded by the Army to Erco Division of ACF Industries, Inc.

Three Missile Firms Get Rapid Writeoffs

Three rocket and missile firms—Aerojet-General Corp., Propulsion Research Corp. and Convair were on the most recent list of firms receiving rapid tax amortization of new facilities.

Aerojet was allowed 60% by Office of Defense Mobilization in certifying $417,740 for research and development facilities.

Accelerated tax amortization to Propulsion Research Corp., also for R&D facilities, amounted to $88,359 at 70%. The Convair certificate for R&D facilities: $17,022,000 at 60%.

Fruehauf Converts Missile Capacity

Fruehauf Trailer Co. is planning to convert the entire capacity of its Delphos, Ohio plant to handle increasing defense contract work, primarily missile ground handling and support equipment.

Company reports it now builds such equipment for six major missile types and is in design and prototype phases for a number of others.

Current projects are *Redstone, Regulus, Thor, Nike Matador* and *Ding Dong.*

Anadite Opens Plant at Hurst, Tex.

Anadite, Inc. of South Gate, Calif., specialist in chemical milling and finishing of aluminum, magnesium and steel, opened a new 20,000 sq. ft. plant at Hurst, Tex. on April 1. Firm will be called Anadite, Inc. of Texas and will employ more than 100.

New facility is situated on a 3-acre site and represents an investment of more thain $500,000.

Republic Gets ICBM Subcontract from GE

Republic Aviation Corp. Guided Missiles Division will build an undisclosed number of Convair ATLAS ICBM nose cone structural units under a $500,000-plus contract from General Electric.

Republic plans to handle tooling and heavy machining for the contract at its plant at Farmingdale, N. Y.

M-H Nets $22 Million Report Sales Up 18%

Minneapolis-Honeywell Regulator Co. reports an 18% increase in sales during 1956 to a record $287,944,462, up from $244,842,068 the previous year. Earnings were $22,463,657 compared to $19,278,648 in 1955.

Insurance Firm to Build Lockheed Missile Facilities

Prudential Insurance Co. has entered into an agreement with Lockheed Aircraft Corp. under which it will provide facilities costing about $14 million and lease them to Lockheed's Missile Systems Division on 25-year terms.

The deal is believed the first in which an aircraft company has used facilities provided by insurance companies as a means of preserving working capital.

In the Lockheed program, Prudential is acquiring title to 83 acres of the 275 owned by Lockheed at Sunny-

A POSTAGE STAMP CAN CHANGE YOUR WHOLE FUTURE

Sometimes little things can be mighty important. For example, a three-cent stamp can put in your hands a complete account of opportunities in the guided missile field.

The guided missiles business is the business of the future, and your future can be brighter with Bendix—the prime contractor for the important and successful Talos Missile.

Here at Bendix you will be associated with many of the world's foremost missile engineers. The work necessarily covers the broadest possible technical assignments with practically unlimited opportunity for advancement.

The thirty-six-page booklet, "Your Future in Guided Missiles", contains exactly the type of information every ambitious engineer should have.

It gives a detailed background of the function of the various engineering groups such as systems analysis, guidance, telemetering, steering intelligence, evaluation engineering, missile testing, environmental testing, test equipment design, reliability, ram-jet propulsion and hydraulics, and other important operations.

Mail this coupon today. It can bring you a brighter tomorrow.

Bendix—prime contractor for the TALOS MISSILE

Bendix Products Division—Missiles
412 I, Bendix Drive, South Bend, Indiana

Product Design and Packaging
Servomechanisms

Ford Instrument Company's new Missile Development Division is expanding because of increased activity on guidance and control work for major ballistic missiles such as the Redstone and Jupiter.

Are you interested in the opportunities this could bring you — and the increased responsibilities? To those engineers who feel they can measure up to the high standards of our engineering staff and who wish to do research, development and design work in the expanding new field of missile engineering, write or phone Allen Schwab for an appointment or further information.

FORD INSTRUMENT CO.
DIVISION OF SPERRY RAND CORPORATION
30-10 - 41st Avenue • Long Island City 1, New York

vale, Calif. and also is taking a 99-year lease on a portion of the research laboratory ground at Stanford Industrial Park, Palo Alto.

Navy Orders *Talos* Missile

Navy has awarded Bendix Aviation Corp. a $27 million contract for quantity production of the ramjet-powered *Talos* surface-to-air missile. First *Talos* deliveries are expected in less than a year and are earmarked for two new missile cruisers—the *Little Rock* and *Galveston*—now undergoing conversion.

Northrop Sets Up Redstone Office

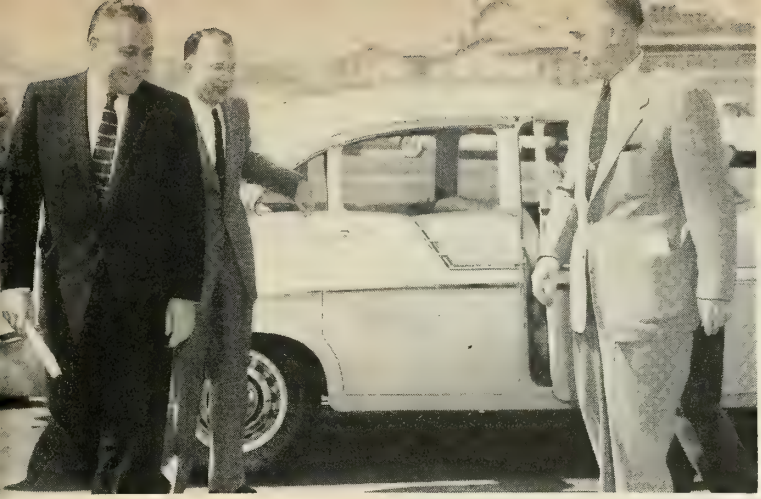
Northrop Aircraft has established an office at Huntsville, Ala. under A. A. Demetriou, former contract administrator of its Anaheim Division.

New installation will represent Northrop's subsidiary Radioplane Co. at nearby Redstone Arsenal.

Thiokol Acquires New Firm

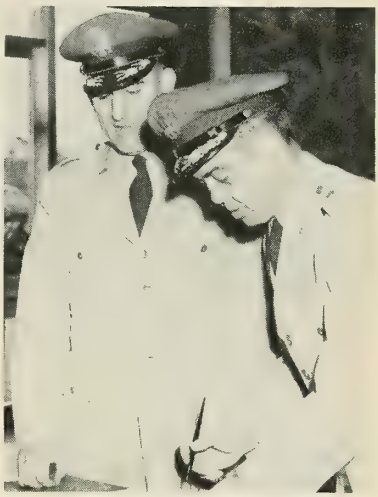
Thiokol Chemical Corp. has acquired full control of National Electronics Laboratories of Washington, D. C. through an exchange of stock. It will operate the company as an independent, wholly-owned subsidiary under its existing name.

Republic Payroll Tops $1 Billion



Republic Aviation Corp. builder of the *Terrapin* upper air research rocket, recently joined the ranks of aircraft manufacturing firms paying out $1 billion or more in salaries when its 1956 payroll reached $1,002,074,000.

Republic paid a year-end bonus of nearly $2 million to put it in the billion-dollar wage bracket for the first time.



$19.5 Million Contract for Associated Products

Martin-Denver has awarded Associated Products Corp., subsidiary of American Machine and Foundry Co., a $19.5 million missile instrumentation contract, presumably for the *Titan* ICBM.

Simultaneously, AMF announced plans for a 28,000-sq. ft. plant expansion in El Monte, Calif. to be used for production and assembly of missile ground instrumentation and check-out equipment and an 18,000 sq. ft. structure at Englewood, Calif., for field engineering.

Dr. Louis G. Dunn, Vice President and Director, Guided Missile Research Division, The Ramo-Wooldridge Corporation, left; Dr. Dean E. Wooldridge, President and Treasurer, Ramo-Wooldridge Corporation and the Honorable Lyle S. Garlock, Asst. Secretary of the USAF for Financial Management arrive at the Western Development Division Headquarters to attend a briefing.

Col. D. F. Miller, left, and Brig. General Don R. Ostrander, register at the Western Development Division for a meeting with Maj. Gen. D. N. Yates, Chairman Guided Missile and Space Vehicle Committee.

Dr. Ralph W. E. Reid, Asst. Director, Bureau of the Budget, far left; Alvin O. Waggoner, Executive Secretary Ballistic Missile Committee, Office of the Secretary of Defense; Wreatham . Gothright, Asst. Director, Bureau of the Budget, sign in at the Headquarters of the Western Development Division while Capt. Dan Babcock looks on.

Maj. General B. A. Schriever and the Honorable Richard E. Horner, Asst. Secretary of the USAF for Research and Development discuss phases of Ballistic Missile research during a visit Sec. Horner made to WDD.

Dr. Clark B. Millikan, Acting Chairman Scientific Advisory Committee, left: Brig. Gen. D. R. Ostrander, Asst. Deputy Commander for Weapons Systems, ARDC, and Committee member George B. Kistiakowsky enter the WDD Headquarters building for a Committee meeting.

ARDC Information Director Col. Albert A. Arnhym, right, gets congratulations after receiving Legion of Merit from Lt. Gen. Thomas S. Power, ARDC Commander.

J. R. Dempsey, formerly program director of the ICBM Atlas project, has been named manager of Convair's new Astronautics Division. Other officers appointed are **K. J. Bossart,** tech. dir.; **Mortimer Rosenbaum,** chief engr.; **H. R. Friedrich,** asst. chief engr. for development; and **Krafft A. Ehricke,** asst. to the tech. dir.

Dale A. Lichty, senior vp, has been elected president of Hydro-Aire, Inc., succeeding **Homer H. Rhoads,** resigned.

Joseph Philipson has been appointed director of Atlantic Research Corp.'s newly formed Western Div. with headquarters at Pasadena, Calif. **Turner W. Ivey** has joined the Chemistry Div. in Alexandria, Va., where he will supervise junior engineers in the production of solid propellant rockets, and in further development of propellant production methods and processes.

LICHTY

DEMPSEY

Dr. L. L. Wheeler, formerly chief engr., has been appointed industrial relations vp of Sperry Gyroscope Co.

Dr. Robert P. Petersen, former dir. of nuclear research for Republic Steel Corp., was elected president of Applied Research, Inc.

Asst. Secy. of Defense **Frank D. Newbury** has been appointed to the newly created position of Asst. Secy. for Research and Engineering, with **William M. Holaday** as his Deputy.

R. L. Cunningham, asst. mgr. of the engineering personnel offices of both the Missile Development division and Autonetics, has been named mgr. of Missile Development division's engineering personnel.

Philip I. Chase, head of the materiel div., has been elected vp-manufacturing, and **Joseph Corie,** asst. to the executive vp, has been elected secy.-treas. of Radioplane Co.

James R. Lewis has been appointed dir. of public relations for The Ramo-Wooldridge Corp. Formerly senior staff asst. in the Guided Missile Research Div., he will continue special assignments on management problems and program information.

Three promotions have been announced by the U.S. Naval Air Rocket Test Station: **Irving Forsten** becomes chief engineer, **Frederick R. Hickerson** replaces Forsten as senior project engineer, and **John J. Canavan** goes from head of the Test Branch to head of Rocket Test Div.

Orrin C. Bowers has been appointed chief engineer of BJ Electronics, Borg-Warner Corp.

Alfred Finzel, former Chief of Structures for the Army Ballistic Missile Agency at Redstone Arsenal, has been appointed Project Engineer in Ramjet Design for the Wright Aeronautical Div. of Curtiss-Wright Corp.

James M. Jackson and **Dr. David S. Stacey,** formerly in charge of the Research Service Laboratories at the Univ. of Colorado, have been named director and technical dir. respectively of the newly formed Ball Brothers Research Corp. at Boulder, Colo. The corporation will conduct research in electronics, aerophysics, optics, servomechanisms, and other instrumentation.

Louis Bucalo has been promoted to asst. chief engineer at Specialties, Inc. and **F. P. Caruthers** has been appointed project engineer at the company's Syosset plant, L. I., N. Y.

Dr. Robert W. Buchele, formerly a faculty member of the UCLA School of Business Administration, has been named staff administrator for Northrop Aircraft's new executive development program.

O. A. Wright, staff engineer for Lockheed's Missile Systems Div., has been appointed engineering mgr. of Actuation Research Corp., Glendale, Calif.

Capt. Marshall B. Gurney (USN, ret.) has been named manager of the Govt. Relations Dept. at Raytheon Mfg. Co.'s Santa Barbara, Calif. laboratory.

C. M. Martenson has been elected vp and gen. mgr. of Hydraulic Research and Mfg. Co. Other company officials announced are: **S. A. Baker,** treas., and **J. R. Haber,** asst. secy. and treas.

NEW 'SHEAR-SEAL' VALVE FOR 10,000 P. S. I.

This new "Shear-Seal" shut-off valve rated for liquids or gases to 10,000 P.S.I. will withstand surges of up to 15,000 P.S.I. without damage to the valve or its leakproof operation. It is designed for a burst pressure of 40,000 P.S.I.

The "Shear-Seal" principle is an exclusive Barksdale development for the control of extreme pressures and has a long history of successful industrial application. Lapped optically flat sealing surfaces of the sealing rings and the mating rotor face are protected by keeping in constant intimate contact; flow is always through the center of the "Shear-Seal" never across sealing surfaces, as in conventional valve design. Sealing qualities actually improve as the self-aligning "Shear-Seals" lap themselves to a more perfect fit with each valve operation. The infinitesimal amount of wear is taken up by a back-up spring.

Valves will be furnished for pipe, tube, AND 150 or any preferred special high pressure connection. For complete information on the "Shear-Seal" design and its application in your particular high pressure valve problem write for "Shear-Seal" bulletin.

TAKE ADVANTAGE OF MISSILES AND ROCKETS NEW SUBSCRIBER SERVICE

DO YOU WANT MORE INFORMATION ABOUT NEW MISSILE AND ROCKET PRODUCTS?

All you do is circle the number on the card to the right that corresponds to the number following the items mentioned inside this magazine.

DO YOU WANT MORE DETAILS ABOUT THE ADVERTISED PRODUCTS OR SERVICES IN MISSILES AND ROCKETS?

These data are yours for the asking. Just circle off the proper number indicated below or next to the particular advertisement you want to know more about. Your request for information will be forwarded promptly to the companies concerned.

MAIL YOUR SUBSCRIBER SERVICE CARD

Today

Will today's defense dollars buy you "mail-by-missile" tomorrow?

A relentless scientific quest is underway today in the secrecy of America's laboratories and proving grounds. The object: to enable missiles to safely "reenter" the earth's atmosphere before searing supersonic heats reduce them to dust. The problem is doubly important—while missiles serve America's defense today, their real future might well be to serve man peacefully—as super-fast mail carriers, for instance, that span continents and circle the globe in minutes.

The impetus of military research programs has generated important progress in this quest. Recent Avco research achievements—in thermodynamics, metallurgy, advanced electronics and inertial guidance, in all the sciences that figure prominently in "re-entry"—create hope for a prompt,

Coming This Month

the Completely Revised

SPRING-SUMMER 1957 EDITION

of the

WORLD AVIATION DIRECTORY

Guided missile expenditures are jumping from $1.1 billion last year to an estimated $1.5 billion this year and over $2 billion (estimated) for 1958. In aviation manufacturing third quarter 1956 figures show a $18 billion backlog—up $4.5 billion over the same period in 1955. In air transportation, total revenue of the U.S. scheduled airlines shows a 14% INCREASE in 1956 over 1955.

With missile spending still rising and the entire aviation industry still very much in a boom, you'll be needing more complete information than ever before for buying—spending—research and reference purposes. Next month the complete WORLD AVIATION DIRECTORY comes off press.

This completely revised 1957 WORLD AVIATION DIRECTORY in its new Spring-Summer Edition packs in all names and job titles of over 21,000 key people in the industry plus listings of more than 6,500 companies. Here, in one handy volume of over 1,000 pages are 27,000 names of executives, companies, their products/services; plus names of organizations, all classified and cross-indexed for fast reference. Included is a big valuable special BUYERS' GUIDE.

avco | Crosley

defense and industrial products

"DEFENSE DOLLARS DELIVER TWICE," *says* Lt. Gen. James M. Gavin, *Chief, Army Research and Development* "For each military application of new scientific discoveries there are many parallel developments for peaceful use to improve the health, comfort and well-being of present and future generations."

Avco's defense and industrial products combine the scientific and engineering skills, and production facilities of three great divisions of Avco: Crosley; Lycoming; Research and Advanced Development —to produce power plants, electronics, airframe structures, missiles, and precision parts.

TODAY'S MILITARY SERVICES, WITH THEIR TREMENDOUS TECHNOLOGICAL ADVANCES MADE POSSIBLE THROUGH SCIENCE, OFFER A VITAL, REWARDING CAREER.

endowed with sight ...and insight

Inquisitive eyes denote the inquisitive minds that made possible today's rocket powerplants. Sharp eyes and minds that have the power to visualize challenging problems . . . *and* the insight to solve them.

Spurred by such long-range sight and insight, RMI has blazed the trail in rocket power for over fifteen years. And today, with new developments in manned and guided flight creating vast new propulsion problems, RMI will continue to lead the way. For RMI engineers and scientists form a talented, far-sighted team, designing and producing advanced powerplants for the vehicles of tomorrow.

Engineers, Scientists—Perhaps you, too, can work with America's *first* rocket family. You'll find the problems challenging, the rewards great.

WE START WITH PLASTIC SHEETS, END WITH STRATO DATA ANALYSIS

uilding the polyethylene balloon, s shown here, is part of General fills balloon systems service. The full package" service, typical of ur thoroughness in other areas of ctivity, includes: design of vehicle nd instrumentation, manufacture nd flight planning—including ieteorological services, flight oper- tions, telemetering, tracking and ecovery, and finally, analysis of ollected data.

Manned strato-balloon flights probe the mysteries of space

This is the Navy Project Strato-Lab balloon that set a new altitude record in a recent ascent at Rapid City, S. D. The fact that Commanders M. D. Ross and M. L. Lewis rose to 76,000 feet, the highest man has flown in a balloon, was incidental. Of far more importance was their demonstration that a light, comparatively inexpensive polyethylene balloon, with a gondola carrying its own atmosphere, is a feasible means of carrying human observers above the present ceiling of sustained powered flight. Manned flights to altitudes of 100,000 feet or more are possible today.

Man has flown higher in a rocket plane, but only for seconds at a time. General Mills strato-balloons can remain at controlled altitudes for days if required. (Thus, "passengers" have time to make detailed observations.) They can also be used as launching stations to give rockets a "head start" into space.

Upper-air research is one of many areas being pioneered at General Mills. Possibly you can profit from our experience in this field—or from our research, development and production of electro-mechanical sub-systems and major assemblies for weapons defense, guidance and controls, and weapons testing. Send today for booklet with all the facts.

Absolute tight shut-off reliability safety • long life

Absolute shut-off dependability and safety is assured with ANNICO TEFSEAL SEATS, proven in severe fuel, chemical and gas services at pressures to 10,000 psi.

ANNIN...*most widely used remote shut-off valves for control of liquid propellants*

ANNIN's ten years of experience in the design and development of valves for rocket and missile ground installations has resulted in a new valve concept which has been *proven-in-service* for remote, manual and throttling applications. ANNIN's complete line is now available for pressures to 10,000 psi and temperatures from −400°F to 1600°F. Write for catalog 1500-C containing data on ANNIN valve bodies, operators and special design features.

INERTIAL GUIDANCE

Few areas of engineering or science offer greater problems—or greater opportunity for achievement—than inertial guidance. At Lockheed Missile Systems' Research and Engineering Centers in Palo Alto and Sunnyvale, engineers and scientists are performing advanced work on all phases of inertial guidance and navigation.

New positions have been created for those possessing backgrounds in mathematics, physics, electronics, servomechanisms, flight controls, precision instrumentation and computer design. Inquiries are invited from those possessing strong interest in inertial guidance.

Here R. G. Rickey (left), components specialist, discusses new accelerometer designs with E. V. Stearns, head of the Inertial Guidance Department.

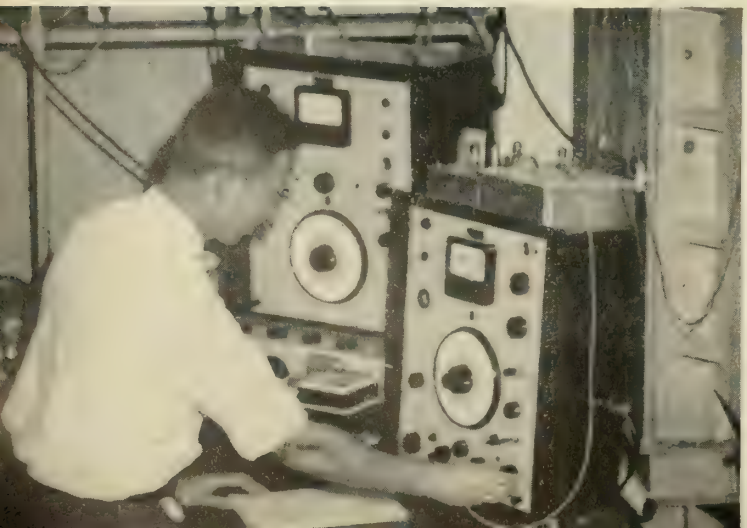
performance test

Brush Recording Systems at Rocketdyne, a Division of North American Aviation, Inc., directly record stress, acceleration, and acoustic values of rocket engines under test.



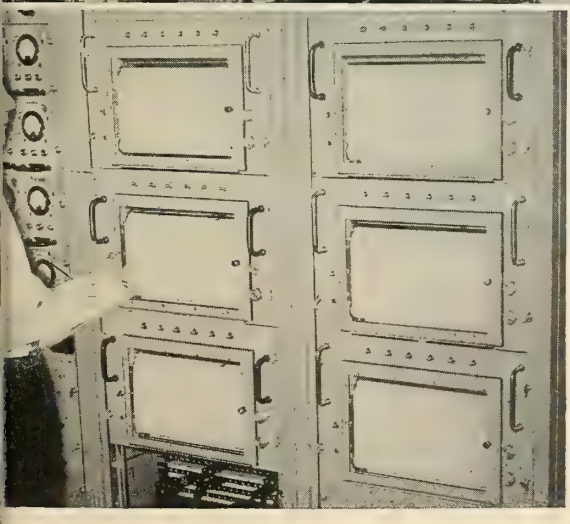
In all types of applications...

45,000 CHANNELS OF BRUSH OSCILLOGRAPHS IN SERVICE

When selecting recording instrumentation for either military or industrial research and development, you want equipment that is proved by experience. Remember—there are more channels of Brush direct-writing oscillographs in use than all other makes combined.

This equipment offers the widest range of recording speeds available, to provide excellent readability for a wide range of signals. You have a choice of ink writing or electric writing, available in console, rack mounted or portable units.

The direct-writing frequency range, from d.c. to 100 cycles per second, covers the great majority of requirements for measurement of physical phenomena. Thus you can instantaneously record stress, strain, vibration, torque, force, and many electrical variables. Select *BRUSH* for equipment backed by unmatched experience.



complete frequency spectrum analysis for noise tests

With a Brush-Bruel & Kjaer Spectrum Recorder, a complete frequency spectrum analysis can be performed in a matter of seconds. This instrumentation operates *automatically*—thus saves hours of engineering time. And it presents recorded data in one-third octave steps—a form in which information is most meaningful and useful to noise reduction programs.

Shown at left is an aircraft test setup measuring loss in acoustic transmission through fuselage wall panels. This is one of scores of complete systems for sound, noise, or vibration analysis using Brush-Bruel & Kjaer equipment.

Official photograph U.S. Navy

telemetering

Over 100 Brush units at the Naval Air Missile Test Station at Pt. Mugu directly record data telemetered from missiles such as the Regulus I. Instruments record an almost limitless variety of functions and conditions, including pitch, yaw, acceleration, pressure, strains, etc.

Another Industrial Challenge

After having been convinced by Rear Admiral Rawson Bennett that the torpedo was the first truly guided missile, our managing editor recently decided to look into the possibility of publishing articles on underwater warfare.

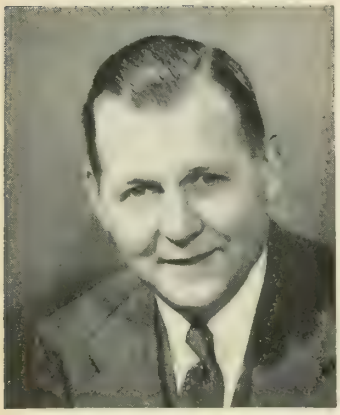
It soon became apparent, however, that today's torpedo and underwater missile systems embrace a whole new technological and strategic undersea warfare concept and that the advances to date called not for just an article or two, but an entire issue devoted to the subject.

This eye-opener of an issue, which was made possible through the kind cooperation of the Navy, of its Bureau of Ordnance and their efficient officers and civilians of the Office of Public Information and Security Review, clearly shows the importance of a continued and meticulous effort on the part of our Navy and industry's missile men to maintain a number one position in this field.

The reason for this is the Russian submarine threat. Naturally, Russia's answer to our overseas SAC bases is a vast missile-launching submarine fleet in addition to their long-range bombers. It is gratifying that our own Navy is aware of this, and that underwater early warning systems and sophisticated torpedoes and anti-submarine weapons are being studied and perfected.

When only ten years ago one would dare to suggest such a thing as launching a rocket from deep under the sea, even the most respected military strategists and engineers would brush the thought off with a condescending smile. Today, as this issue of m/r indicates, highly advanced underwater missiles of all kinds are being rushed through development and test.

With the advent of truly submersible atomic submarines that can cruise at high underwater speeds for weeks on end and with the growing practical knowledge of guided missiles of all types, the oceans assume a new strategic significance.



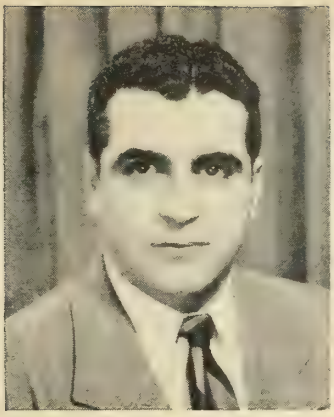
Water covers 71 per cent of the earth's surface. In places its depth exceeds 30,000 feet. It's a restless, moving thing that may stabilize the peace on earth; it is a world in hiding—one in which much of tomorrow's warfare may be conducted if major conflict arises.

One perfectly obvious aspect of the underwater missile science is the technological challenge it represents to our industry. It opens up a whole new field for designers, engineers and scientists. Our great missile manufacturers have new business opportunities, limited only by the vast defense system needed to keep our country safe against a huge fleet of deadly underwater platforms from which enemy missiles can be launched.

WAYNE W. PARRISH

SPERRY ANNOUNCES

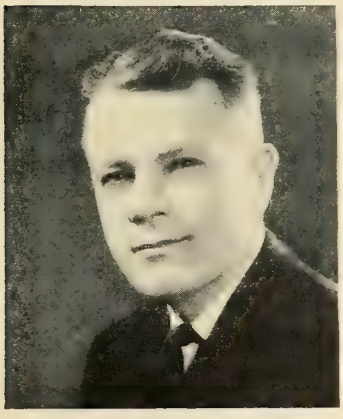
TWO NEW WEAPON SYSTEMS DIVISIONS



CARL G. HOLSCHUH, *President of Sperry Gyroscope Company.*

"In the years ahead, the nation's requirements for new and more efficient weapon systems, delivered at maximum speed and minimum cost, will impose greater demands on industry. For its part, Sperry is moving to meet these demands with the formation of our new Air and Surface Armament Divisions.

"Objective of this product-team realignment within the Sperry organization is to assure more advanced design, shorter lead times and lower costs in the development of weapon systems in these two categories. Each division, with its own engineering, manufacturing and contract organization, includes specialists in radar, fire control, gyroscopics, navigation, inertial guidance and all the allied sciences essential in the engineering of complex weapon systems."



C G Holschuh

SAMUEL AGABIAN has been appointed Manager of the Air Armament Division. Formerly works manager, Mr. Agabian is an Annapolis graduate and former Marine Corps officer. His work at Sperry has included responsibility for computing gunsights, bombsights, antiaircraft devices, radar and infrared developments.

AIR ARMAMENT

Air-to-air missiles and systems
Air-to-surface missiles
Airborne radars
Airborne beacons
Airborne electronic countermeasures
Bombing-navigation systems
Aircraft fire control radars
Airborne inertial systems

MYRON D. LOCKWOOD, manager of the Surface Armament Division, was formerly a systems engineering director. A World War II Lt. Col. of Artillery, and military-technical advisor at M.I.T., Mr. Lockwood has been associated with Sperry projects in underwater torpedo fire controls, guidance computers for missiles, antiaircraft control systems and inertial navigation equipment.

SURFACE ARMAMENT

Surface-to-surface missiles
Surface-to-air missiles
Ground and shipboard search radars
Ground and ship tracking radars
Battlefield surveillance equipment
Mortar and artillery locators
Land, ship and submarine fire control systems
Computers
Land and ship-based transmitters
Weapon direction systems
Ground and ship-based electronic countermeasures

have an idea in your hip pocket?

Then we have an idea you'll be happiest at Firestone . . . where ideas are most likely to see the light of day and breathe the air of success. Here, too, you'll discover benefits and attitudes that inspire more ideas, more success.

Ideas—and men with ideas—have kept Firestone at the top of the pioneers-in-progress list for 57 years. You'll find stimulating projects in our Los Angeles development program for the Army's Corporal . . . or an equally exciting challenge in the new Firestone Engineering Lab in idyllic Monterey—Carmel-by-the Sea. In both efforts, our research teams are staking out some important new claims on history-making concepts in guided missiles and related fields.

Here are just a few specific fields where you as an ME could shine:

Aerodynamics
Structures Air Frame
Stress Analysis
Propulsion System & Component Design
Materials & Process

A man at Firestone has some good ideas on your future. Write him!

CENTURY MODEL 409D RECORDING OSCILLOGRAPH

Numerous agencies engaged in the manufacture and evaluation of missiles have turned to the Century Model 409D Recording Oscillograph as a reliable means of collecting missile performance and control data.

On-board mounting eliminates the necessity for the costly and often not reliable RF link.

The ruggedness and reliability of this 12-channel oscillograph have been demonstrated many times. One agency reports having recovered 42 satisfactory record rolls out of 43 firings. Another, using special mounting configuration, reports recording at 60 G's without damage.

This 13 lb. instrument is compact enough to be installed in most missiles and all electrical connections including remote control are accomplished through a single multi-pin AN connector.

New facilities for new weapons

YOU ARE looking at the entrance to the new Honeywell Ordnance headquarters in Hopkins, a Minneapolis suburb.

These new facilities plus the engineering branch in Monrovia, Calif., the development lab in Seattle and a production plant in Minneapolis, will bring to over 372,000 sq. ft. the space devoted to development and production of *Customized* Weapons systems bearing the trademark of the Honeywell Ordnance Division.

These systems range from infrared detectors to stabilized platforms.

Experts in our Ordnance Division can draw upon a pool of over 30,000 skilled men and women in research, engineering, design and development, production and field service.

Standing behind them is over seventy years of engineering and production know-how.

If you require development work in the areas of missile equipment, fuzing, fire control, underwater ordnance or special products, Honeywell Ordnance Division would welcome your inquiry. Phone, wire or write to Honeywell Ordnance Division, Dept. MI-5-133, Hopkins, Minnesota.

Honeywell Customized Weapons Systems

Warheads; Infrared detectors and systems; Test, checkout and training devices; Transistor converters, inverters, rectifiers; Thermal batteries; Mechanical electro-mechanical and electronic fuzing; Sonar detection systems; fire control systems; Stabilized platforms.

Creative Mechanical Engineer: Previous to his latest promotion, this engineer worked on accelerometers, inertial devices, cooling units, servo-mechanisms and new techniques of gearing for subminiature computer units which will key future development of military weapons. Associates investigated new concepts in magnetic recording and number display devices, and read-out printers. *Do you belong here?*

Electronic Test Equipment Engineer: Also promoted, this man forme provided instrumentation to test advanced airborne bombing a navigational computers. He analyzed test specifications, selected a designed test equipment; originated test procedures. Opportunit exist in systems, manufacturing, tool and cost engineering, prod improvement, and automation research. *Do you belong here?*

mponent Engineer: This man's job entailed the selection, evaluan, development, and application of electronic component parts, or ilding blocks, used in airborne bombing and navigational systems. gineers and physicists will find stimulating opportunities here to gineer on precision analog components, gyros, accelerometers and alog-to-digital converters. *Do you belong here?*

Inertial Systems Engineer: Before his recent promotion, this man performed technical analysis, design and development of inertial guidance equipment. He specified and supervised development to determine the performance, configuration, design, and operation of inertial and missile guidance equipment. Opportunities for mathematicians, physicists, E.E.'s and M.E.'s. *Do you belong here?*

these are now open!

rganized only 19 months ago, IBM Military Products ivision has grown enormously. At Owego, N.Y., IBM deins and manufactures advanced airborne analog and gital computers for Air Force bombing-navigational equipent. At Kingston, N.Y., IBM builds the world's largest ectronic computers for Project SAGE, part of our nation's ant defense net.

The electronic computer field offers engineers and scitists one of the best ground-floor career opportunities day. Economic experts rank the electronic computer in portance with automation and nucleonics in growth otential. Sales at IBM, the recognized leader in this fastowing field, have doubled, on the average, every five years nce 1930. Engineering laboratory personnel has quintupled in the past five years alone. $19,000,000 was spent on research and new product development in 1956.

As a member of IBM Military Products, you enjoy the stability and security of the IBM Corporation, plus the opportunity to progress in any other IBM division. The "small team" system assures recognition of individual merit. Promotions open up frequently through rapid expansion. Company-paid benefits set standards for industry. No wonder the rate of personnel turnover at IBM is less than one-sixth the national average!

For the facts about an engineering career with IBM Military Products Division, just write, outlining background and interests, to:

R. A. Whitehorne,
Mgr. of Engineering Recruitment, Dept. 6905
International Business Machines Corporation
590 Madison Avenue, New York 22, N.Y.

Where would YOU like to work for IBM?

Disclaimer

To the Editor:

Regarding my Pentagon cleared article, "Spacepower," which you published in the April issue of MISSILES & ROCKETS, I would like to make the following comments for the benefit of you and your readers: . . . that due to my impending transfer of positions to the Martin Company from the Air Force, that any identification of my name with my present or former employer, carry a disclaimer "that my views do not reflect those of the Martin Company" or the Air Force.

Although I realize that it is an editor's prerogative to change titles and subtitles, your switch of my original subtitle: "An Analysis of Some Aspects of Space Doctrine" to "How the US Air Force Will Become the US Space Force," gave a new and different connotation to the real content of the article, which has caused me some embarrassment . . . Many readers of my article might assume that the *Vanguard* program, of which the Martin Company is the prime contractor and with which I am intimately connected, has political and military applications. The only purpose of the *Vanguard* —earth satellite program is a peaceful. scientific pursuit—to extend man's knowledge of the earth and its environs.

Donald Cox
The Martin Co.
Baltimore 3, Maryland

R-W Function Spelled Out

To the Editor:

. . . Enjoyed reading your excellent April issue; particularly the comprehensive roundup on Air Force long-range missile activities. We thought all portions were very adequately treated and were pleased to note that the role of The Ramo-Wooldridge Corp. was set forth in a very creditable and understandable fashion . . .

J. R. Lewis
Director, Public Relations

Chicago 41, Ill.

We are planning a forthcoming issue which will feature servo motors and related equipment.—Ed.

H. S. Rocket Courses?

To the Editor:

I was very interested in the letter by Leon Leonard of Seattle in the March issue, since I am associated with what is apparently a group similar to the one he describes. In my case the name is the Wakefield Rocket Society of Wakefield High School, Arlington, Virginia.

I very heartily agree with Mr. Leonard that high school student interest in Rocketry is being neglected and that this is a crucial phase of missile education. An account of our Society and its activities may give your readers an idea of what is being done and what can be done with this age group.

About three years ago George Pickard, a tenth grade student in the Arlington schools, decided to implement his growing interest in Rocketry. He gathered the nucleus of what eventually became the Wakefield Rocket Society . . . now in its second year.

Little was accomplished the first year, but this year's accomplishments were

interesting. Upon application, the group was accepted as an official Moonwatch team; work is now in progress on the construction of the observing station.

In cooperation with the University of Maryland, the group is building a cosmic ray recording station. Several visits have been made to local scentific installations; weekly meetings are "operation bootstrap" in missile education. Six of

the group ushered at the recent ARS convention. I must mention also that difficulties associated with actual launchings have led to the construction of a static test stand, and a program of experimentation with powder and liquid propellants is under way.

This is a good record of accomplishment and were such clubs not so important I would not go on to complain. Yet I feel I must, and my complaint is directed toward that same indifference Mr. Leonard mentions.

I was surprised to read that Mr. Leonard has received assistance from the Northwest Section of the ARS; the parent organization does not appear to have the perception of its Northwest branch. Our efforts to become associated in some way with the ARS have come to nothing.

Reason given is that the Society is afraid of incurring liability in case of accident. I cannot help but feel that this attitude is a tragic mistake; these boys are the scientists of tomorrow.

We must remember that our educational system depends upon people choosing their careers and not being ordered into them. The ARS should have an active program designed to interest capable students now in secondary school.

Other than Reed Research Inc. in Washington, D.C. we have had little success in attracting the attention or interest of industrial research organizations. At one time, Atlantic Research gave some evidences of interest but nothing has developed.

Several individuals have been very kind, but what we need is room for firing, equipment, and the advice of people more technically competent in this field than I.

In closing, I should like to predict that the number of rocket societies will grow in the next few years. The publicity given missile work makes growth inevitable. I hope this letter stimulates some group to step in and assume some of the responsibility practicing scientists owe to these student groups.

David W. Saltus

Arlington, Va.

Watch Your Language!

To the Editor:

Re your answer to Albert Parry in Letters April 1957—All I can say is:

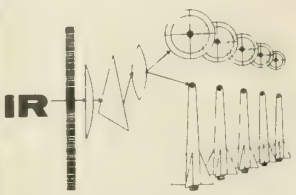
Жиперс, Ватта Дерти Трык!

Also—where does the Lintz Basalt occur?

Kelly Choda
732 Ursula Street
Aurora 8, Colorado

It's a volcanic deposit. Lintz Basalt, in particular, comes from Germany.—Ed.

But Has It Been Cleared?



To the Editor:

Recently in cleaning out my desk, I came across the following, which may be of interest to your readers:

PROJECT VOGELHUNDT

"Firing of rockets, bombs, missiles, and projectiles in tests at NOTS are accomplished in tests of one kind or another. The conducting of a survey prior to the current reports period (1956) indicates that out of approximately more than 200,000 total rounds fired altogether per year and valued at some million and a quarter dollars, it is desirable for study purposes to recover about 20,000 having a total approximate value of about half a million dollars in all. However, further accumulation of data statisticswise showed that of these 20,000, only 10% were usually

INFRA-RED IS ULTRA-MODERN

In the post-war years, the development of infra-red devices has attained the dimensions of a technological breakthrough. In this period, the Electronics and Guidance Division of Aerojet-General Corp. has become the national leader in the development and manufacture of infra-red equipment.

Aerojet offers qualified engineers and scientists unparalleled opportunities in every area of the guidance and propulsion field.

letters

recovered and 90% had a strong recover incapability.

"Optical, auditory, and shock-sensitive devices developed this year have proved of but slight value either costwise or information-contentwise. Some detection methods are valued on the order of 20 times the material recovered.

"In 1956, however, it was noted that olfactory processes, at least in organic fields, are among the most sensitive of sensing devices. If the cost dollarswise of the search-and recovery processes could be reduced to a cost calculated centwise, by using scent-sensitive sensing equipment, it appeared sensible to develop and prove the technique which seemed sensational.

"Mechanical sensors were found impractical, but a careful study of current literature revealed that many varieties of organic sensors are available in large quantities and at low cost.

"After intensive study, it was found that one highly specialized organic sensor, the Bassett Male Aero Bark X3A was suitable as an olfactory detection unit, but that this unit would not operate without a corresponding sensitizing unit to sensitize the weapons before firing.

"Organic sensitizers need not be restricted to the Aero X3A; so several varieties were obtained, including Mastiff Female Yipe 6 and Setter Female Yipe 8. All apparently had equal sensitizing capability and were used in turn to sensitize missiles to be fired at the Randsburg Wash Range.

"Test projectiles were fired in groups of 40 because it was found that the Bassett Aero X3A became insensed after a period and had to be recharged.

"On three tests, in which 120 missiles were fired, the Aero X3A was stationed in a shelter near the anticipated target area. One hundred nineteen of these landed in the target area and were located by the Aero X3A in rapid succession. The average time for search and detection was 0.71 minutes. However, projectile No. 73 accidentally was fired at high gun elevation, and the projectile landed in the foothills of the Panamint Range. Operations had to be suspended because the Aero X3A left the field of operations at approximately more than 121.3 fps, and it was approximately one hour before the Helicopter Recovery Group was able to effect the capture of this sensing unit and return it to the operations area.

"It is the consensus that if some more effective means for stimulating the unspecialized sensitizing units can be devised, olfactory detection will provide an effective and economical means of recovering valuable test weapons after firing. Censing the projectiles before firing, the sensor could be more effective. It is also anticipated that the use of more than one Bassett Male Bark Aero X3A will considerably reduce the wear and tear on these units. It is also believed that the addition of one or more Bassett Female Yipe Aero X3A's will assure a constant supply of these valuable units."

Alexandria, Va.

Plaudits for Us

To the Editor:

I had the pleasure this week of being given a copy of your new magazine, MISSILES & ROCKETS. A colonel who was attending our course of familiarization on Electronic Countermeasures thought that it might be a valuable source of information for our guided missiles lecture. We have really found this to be so.

We present this course every week to high ranking officers of all services, including the Royal Air Force and the Canadian Air Force . . .

R. Kevin Murray
Captain, USAF

Keesler AFB, Miss.

Fashions in the Sky?

To the Editor:

At the suggestion of the New York office of *American Aviation* Magazine, I am writing you to see if you can give me an approximate date for the launching of the New Earth Satellite. We understand that this will take place sometime during the summer.

It may seem strange for a retail store to be interested in such a highly scientific project, but we feel that it might be interesting to tie in some of our ad copy with the launching of the satellite.

Alison M. Beyea, Fashions
New York Office
Neiman-Marcus
1457 Broadway
New York 18, N. Y.

No date has been set yet. It depends on when the launching vehicle is in satisfactory condition. This may not be until the middle of 1958.—Ed.

Wants Red Missile Sources

To the Editor:

Your map on pages 40 and 41 of the February m/r, depicting the Soviet missile industry was very interesting. However, in the European Russia region the map was pictorial but confusing. Association of some symbols on the map with the nearest locality indicated conflict with information we already have on hand, some symbols were simply impossible to locate satisfactorily, etc.

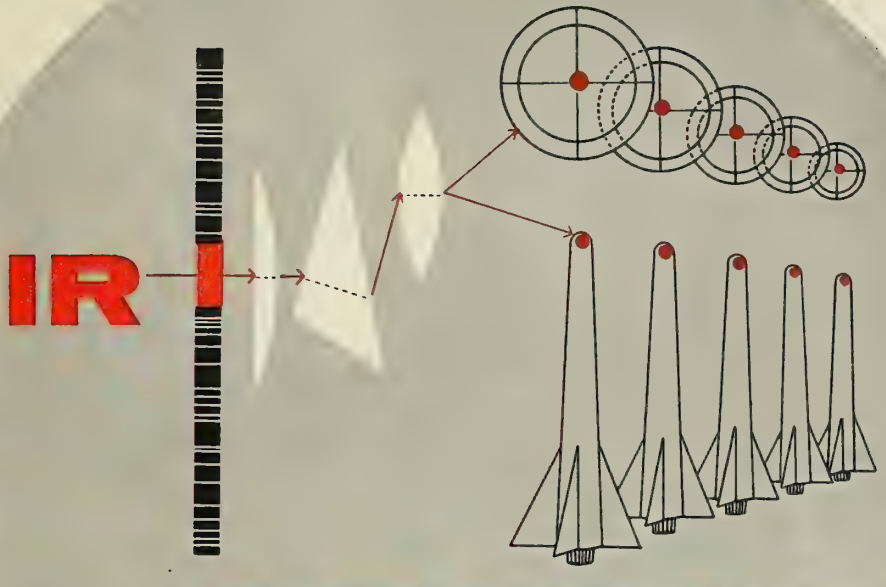
Could you possibly furnish me with some of the specific information that was on hand when the map was drawn up, or indicate the sources and channels thru which the information was obtained?

It is thru the particular responsibilities and interests attached to my work as a Research Engineer in Missile Development Division of North American Aviation that I am interested in such information.

J. D. Harmon
11351 W. Olympic Blvd.
Los Angeles 64, Calif.

We cannot give our sources beyond saying that they consist of Governmental and private sources both in the U.S. and abroad.—Ed.

Emancipation Revisited



To the Editor:

This has been getting chuckles in Florida and San Diego.

I thought you might appreciate—

"GETUSABIRD ADDRESS"

Electronics engineers...physicists...Aerojet invites you to pinpoint your own targets, "lock on" your own future... in the dynamic new field of infra-red.

Man's electro-mechanical partners are bringing his ideas to life faster...better...at less cost

Today one of industry's most formidable tasks is to streamline and shorten the time-consuming process that transforms ideas into exciting new products.

Never in man's history has this embryonic period needed to be shortened more than now—when technological superiority could very well be the world's best hope for peace.

And nowhere is this challenge being met more energetically than in the development and production of automatic control systems at AUTONETICS. For instance. *Numill*—a new automatic machine-tool system invented by AUTONETICS—often turns the engineer's rough sketch and mathematical notations into prototype parts more rapidly than he could reach the blueprint stage with previous methods.

Standardized "postage-stamp" circuits allow engineers to mockup even highly advanced designs almost as simply as they would plug in an electric shaver. And AUTONETICS' data processing equipment can simulate a wide range of operational missions, as well as solve the most involved mathematical problems in minutes instead of days.

AUTONETICS' ability to save time and money between concept and product delivery is reflected in every area of its electro-mechanical technology: flight controls, inertial navigation, armament controls, computers, and other complete systems for the military and industry.

For detailed information, or for employment in this dynamic field, write: AUTONETICS, Department MAR-73, 9150 E. Imperial Highway, Downey, Calif.

dedicated to the proposition that all components are created equal.

"Now we are engaged in a great testing program, testing whether that component or any component so created and so designed can long endure.

"We are met on a great flight path of that program. We have dedicated a portion of that flight path for a final resting place for those missiles that here went down range, that this base might continue to exist.

"It is altogether fitting and proper that we can do this. But in a larger sense, we must test; we cannot rest; we must justify this program.

"The brave men, officers and contractors who have built their empires here, have justified it far above our poor power to add or detract.

"The people will little note, nor long remember what we say here, but they can never forget what we did here. It is for us, in Florida, rather to be dedicated here to the unfinished task which they, at San Diego, have thus thrust upon us.

"It is better for us to be here completing the diminishing tasks remaining before us: that from the public we take increased taxes for this cause for which they gave the last full measure of approval; that we here highly resolve that these taxpayers shall not have paid in vain; that this base, under ARDC, shall have a new birth of accomplishments: and that missiles of the contractor, by the contractor, and for the contractor shall be launched from this base."

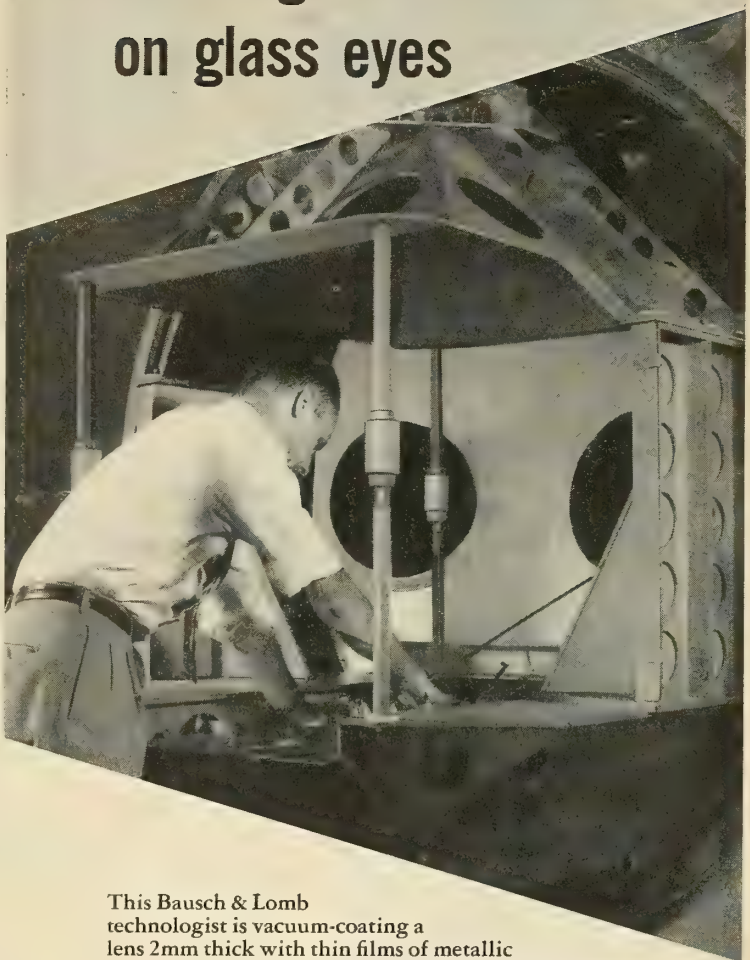
It is in the mail.—Ed.

Russian Carbon?



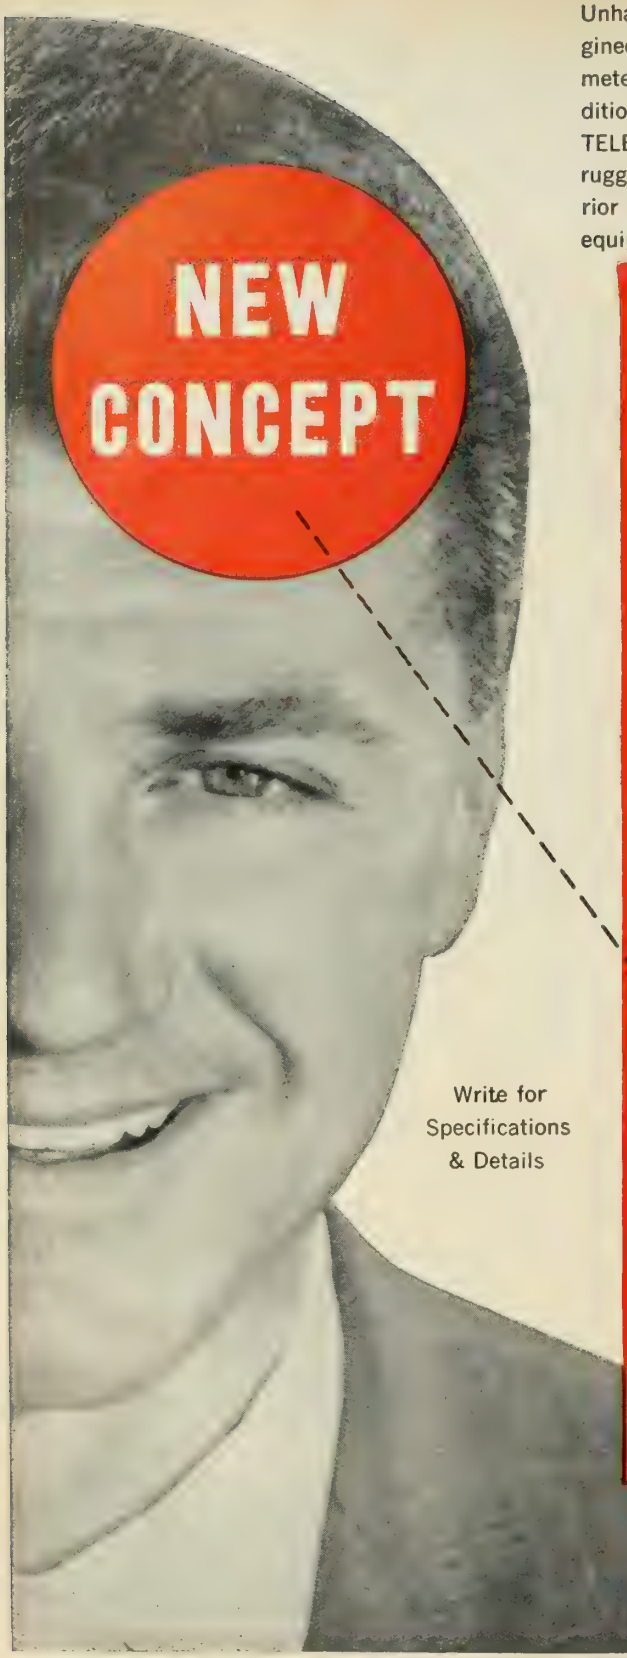
To the Editor:

I have just seen another Russian drawing on the earth satellite project.

It looks as if Mr. Dobrovolsky didn't make such an obvious copy of the Mouse as was done in the drawing that you reproduced last November. I don't know whether this latest Soviet satellite conception is the result of copying some other American design or represents some original Russian thinking on the subject.

Incidentally, this February, 1957, issue of Nauka i Zhizn also carries a five-page article by Varvarov titled "Artificial Earth Satellite." Included is a black-and-white drawing of a three-stage satellite launching rocket and sections on "Theoretical Premises", "Satellite Projects", "Methods of Launching the Satellite", "The Avanguard (Vanguard?) Project",

Grafting metal skin on glass eyes



This Bausch & Lomb technologist is vacuum-coating a lens 2mm thick with thin films of metallic salts to increase control of light and color. If the lens were enlarged to the height of Mt. Washington (6,288'), the lens coating would be equivalent to a four-inch transparent layer. This submicroscopic surfacing method, developed by B&L, makes possible miracles in selective reflectance and transmittance of light of any specified wavelengths. Practical applications range from color TV to directional control of guided missiles. How does this kind of advance technology fit in with your contract plans?

Is Gravity Constant?

To the Editor:

I would like to know your reference for the statement in "Missile Miscellany," of the March m/r, which says that "a gravity pendulum with a bismuth bob gains one beat in 17.432 by another pendulum of exactly the same oscillation length having a zinc bob." I would also like to know if the figure, 17.432, should not be 17,432. This sounds a little more reasonable.

Congratulations on a fine publication.

Richard E. Brown
41113 Menlo Dr.
Wichita 17, Kansas

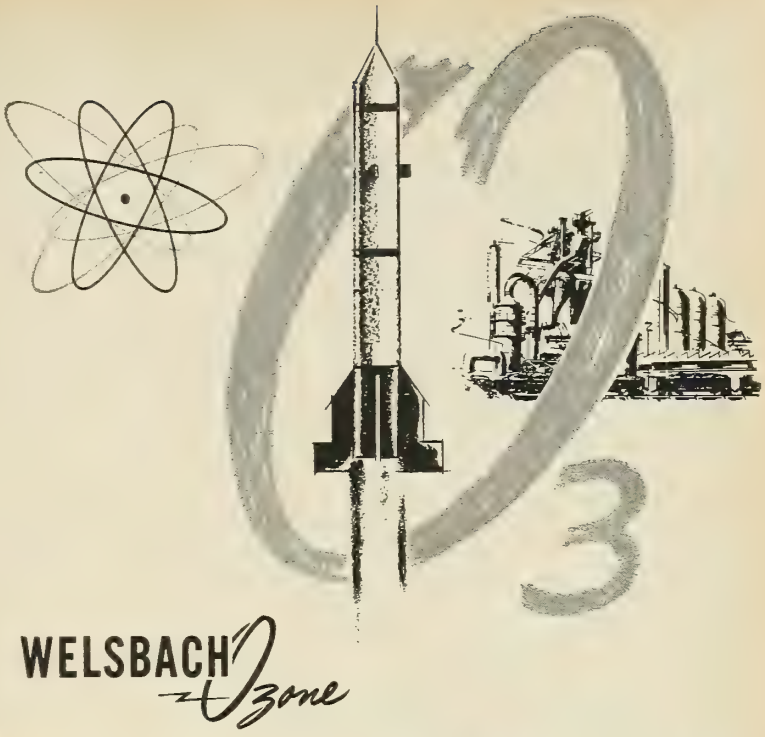
The figure 17.432 as printed is correct, which means that the shift in period is quite rapid—Ed.

To the Editor:

In the February m/r "Missile Miscellany" section you state: "Has any one ever used modern theory to explain why the silicate, Lintz basalt, spontaneously generates heat at the rate of 2.38 x 10-4 calories per hour per gram; why *in free fall it won't accelerate at 980 centimeters per second?* It's not radioactivity, for uranium is 1500 times as active as Lintz basalt, generates only 7.2 x 10-5 cal/hr/gr."

In an attempt to get an explanation, this paragraph was shown to two physicists. Their reaction was to dispose of the problem by exclaiming, "Hogwash!". I am not inclined to dismiss this alleged phenomenon so lightly, but must admit that I am more than a little doubtful of the validity of the assertion regarding the acceleration of Lintz basalt in free fall.

I would, therefore, appreciate more detailed information on the subject, if at all possible. Also, I would very much like to know the source of your information.



C. C. Barnett
General Electric Co.
Missiles & Ordnance Systems Dept.
Philadelphia 4, Pa.

Our experience is that those who claim "hogwash" merely assume it, have never checked it. A letter is in the mail giving you complete references—Ed.

To the Editor:

It's interesting to see that you're stirring up the relativity time-contraction controversy sparked off over here by a letter from Prof. Dingle in "Nature," and continued both there and in "Discovery" by most of our "big guns" in relativity theory.

Lead v. bismuth pendulums—I sup-

WELSBACH Ozone

..new horizons as an oxidant

Ozone provides one of the most versatile oxidants available today. It has the added advantage of introducing nothing but oxygen to the reaction.

Low in cost, efficient and always available, ozone produced by a Welsbach Ozonator might just be the answer to your oxidation problem.

Glance at a few of the applications listed below in which ozone has proved to be a better oxidant. One of them might parallel your problem . . . with ozone the solution:

- *Removal of corrosive chlorides in nitric acid recovery following atomic fuel extraction.*
- *Oxidant for rocket fuels.*
- *Chemical synthesis reactions demanding specificity and purity in the oxidant.*
- *Removal of cyanide or phenol from wastes.*
- *Oxidation of oleic to azelaic and pelargonic acids (replaces chromic acid.)*
- *Improving oxidation characteristics of mineral oils.*
- *Elimination of many industrial and sewage odors.*
- *Purification and elimination of undesirable taste, color, and odor in municipal water supplies.*

. . . and a host of new applications still being researched.

If your process calls for an oxidant, it is almost certain that Welsbach ozone will do the job better and at less cost. Why not contact Welsbach.

Write for this booklet on Welsbach Ozone Generation for Industrial Application. Please indicate Company and Title.

ASCOP... first with performance data on America's first jetliner!

When the Boeing 707 — America's first jetliner — enters service on the air routes of the world, seven years of development will be behind it. The most tested airliner in aviation history, prototype of this 600-mile-per-hour plane has already been flying for two years . . . has already been ordered by eleven famous airlines.

To check and to record details of the 707's performance during development, Boeing has used telemetering equipment by ASCOP. Using the ASCOP D-Series Low Level Telemetering system, with C-Series airborne Monitor equipment, Boeing can "read" the 707 to an accuracy of better than 1%. As many as 580 channels of data may be sampled, transmitted and/or recorded, with simultaneous monitoring.

ASCOP has the "packaged" answer to data-recording for your project, too . . . whether it involves aircraft, missiles or other vehicles . . . operational or static testing. Our engineering staff stands ready to consult with you, without obligation.

M SERIES GROUND STATION

ASCOP DATA REDUCTION EQUIPMENT

ASCOP Pulse Width Ground Station equipment complements ASCOP PW Multicoders and radio telemetering sets to provide complete "packaged" systems for operational testing of aircraft, missiles and other vehicles and for static testing of engines, rockets, nuclear reactors, etc.

MC-1 MONITOR CONSOLE GROUP

ASCOP DATA ACQUISITION EQUIPMENT

CMS-2 MONITOR SCOPE

Provides rapid inspection and monitoring of airborne or test stand data **before** or **during** runs. Samples data at 1¼ to 30 repetition rates per second. Provides reliable performance under extremes of vibration acceleration etc.

LOW LEVEL PW MULTICODERS

Provides super-sensitive low-level remote measurement of data from airborne vehicles. High input sensitivity, fast sampling rate, wide selection of data channels.

pose someone has investigated the possibility of eddy-current damping from the Earth's magnetic field? If this, and the Lintz basalt phenomenon tie up together, we might get a real anti-gravity unit.

Astropsionics?

I'd like to comment on certain aspects of some of the serious articles, but I'm a bit scared of security—there have been instances of people being refused permission to use material in public lectures here in spite of it actually being published; that recent leak of "Sea Slug" also had security types going round in small circles, tho' what actually got out couldn't be of the least value to the Queen's enemies, as far as I can see. Still, I suppose that it's a question of principle.

P. H. Mabey
201 Bath Road
Cheltenham,
Glouc., England

To the Editor:

. . . I have come across an article in your magazine which has stirred much interest. The article appeared in m/r, March 1957, page 113:

"Relatively also requires the equivalence of gravitic and inertial mass. If so, explain why a gravity pendulum with a bismuth bob gains one beat in 17,432 by another pendulum of exactly the same oscillation length having a zinc bob; and why torsion pendulums act similarly."

Can you please supply me with the source of your information?

Who made this discovery? If this is true, isn't g dependent on mass? . . .

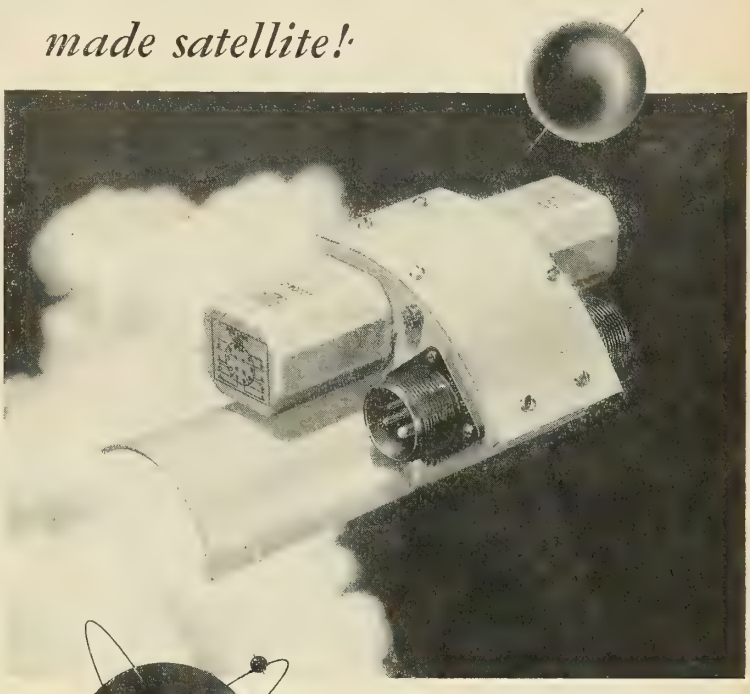
Alfred F. Kudela
Senior Engineer,
Chrysler Corporation
P.O. Box 2628
Detroit 31, Mich.

This phenomenon may have some bearing on the theoretical g-mass relationship. More likely it has to do with diamagnetism. In any case it appears to be a phenomenon that's been looked into only a little. The reference is Journal of the American Physical Society, Volume XVIII, No. 2, page 125, a paper presented by Charles F. Brush.—Ed.

On Vanguard Switching

To the Editor:

I am very interested in astronautics and m/r is the fulfillment of my dreams in the field.



In an article about the *Vanguard* Project, I saw that there was a sun-cell to reset a memory unit in the satellite once every circuit. What happens if the satellite is rotating on its axis more than once per circuit? Looks like the memory unit would erase information already stored, but not yet transmitted, and a great amount of information would be lost. Do you have any information on how this is being remedied, or is it?

Also where could I get an index for m/r and pictures of rockets, missiles, and planes.

Drew Evans
207 Taft Ave.
Wilmington 5, Del.

Vanguard's switches are programmed to act relative to its orbiting cycle. An m/r index will be published this fall. For pictures we suggest you try the public relations offices of companies involved—Ed.

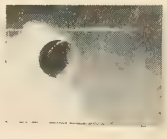
bernco-made *controls used on world's first man-made satellite!*

bernco

Controls
Test Equipment
Wiring Harnesses
Thermocouples

An opportunity to work on the first man-made satellite was not an everyday occurrence. BERNCO's "down-to-earth" creative craftsmen welcomed the challenge.

Like other BERNCO controls, the specifications for controls on the satellite rocket were carefully screened, quality standards were rigid and production was 100% inspected.



The finished controls are *reliable* at *reasonable* cost because of BERNCO's quality control system and production techniques.

It will be a while before the earth satellite is eventually orbited in space. In the meantime, BERNCO would like to be of service to you.

BERNCO offers a *complete* service in the design, production and environmental-testing of electrical, electronic or electro-mechanical component parts—*completely customer designed, partially* BERNCO *designed* or *completely* BERNCO *designed.*

Try BERNCO, where rocket and missile electrical components are a specialty.

JUST OFF THE PRESS! A new illustrated brochure will help acquaint you with Bernco's service and facilities. Write for your copy, now!

Stratos' Model GEA120-1 air conditioning system being prepared for production test.

Outline of 1000 Temperature-Pressure Problems

Any rocket engine looks simple in silhouette—but its 150 or more parts present new and complex problems of operating temperatures and pressures. This is the reason why The M. W. Kellogg Company, leading designer and fabricator of industrial high temperature, high pressure vessels and steam power piping, was assigned a major role in the development and production of over ten different guided missiles to date, including the Terrier.

Steam power piping and rocket motors, for example, have much in common. In the latter, nozzle temperatures are around 5000 deg. F. and pressures 2000 psi. In steam-electric power plants, the Kellogg assignment concerns piping to withstand 1250 deg. F. and pressures over 5000 psi. Both problems include selection or development of not only the proper alloy to provide correct strength-weight relationship and resistance to corrosion or erosion, but also the welding techniques, materials, and skills to fabricate the alloy into large or intricate shapes.

M.W. Kellogg's long fabricating experience with high temperatures and pressures can be a valuable asset to all manufacturers concerned with the rocket program, and to those responsible for process equipment in the petroleum or petrochemical industries.

AIRCRAFT COSTING MILLIONS...

NO PHOTO

...ARE PROTECTED BY THE B&H JETCAL® ANALYZER

Two of the most important factors that affect jet engine life, efficiency, and safe operation are *Exhaust Gas Temperature (EGT)* and *Engine Speed (RPM)*. Excess heat will reduce "bucket" life as much as 50% and low EGT materially reduces efficiency and thrust. Any of such conditions will make operation of the aircraft both costly and dangerous. The *JETCAL Analyzer pre*determines accuracy of the EGT and (interrelatedly) Tachometer systems and isolates errors if they exist.

The *JETCAL* ANALYZES JET ENGINES 10 WAYS:

1) The JETCAL Analyzer *functionally* tests EGT thermocouple circuit of a jet aircraft or pilotless aircraft missile for error *without running the engine or disconnecting any wiring.* GUARANTEED ACCURACY is ±4°C. at engine test temperature.

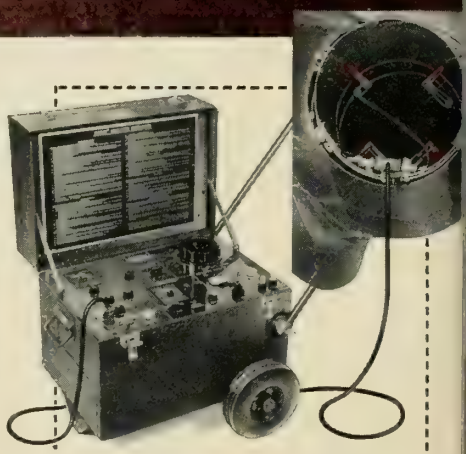
2) Checks individual thermocouples "on the bench" before placement in parallel harness.

3) Checks thermocouples within the harness for continuity.

4) Checks thermocouples *and* paralleling harness for accuracy.

5) Checks resistance of the Exhaust Gas Temperature system.

6) Checks insulation of the EGT circuit for shorts to ground and for shorts between leads.



7) Checks EGT Indicators (in or out of the aircraft).

8) Checks EGT system with engine removed from aircraft (in production line or overhaul shop).

9) Reads jet engine speed while the engine is running with a guaranteed accuracy of ±0.1% in the range of 0-110% RPM. Additionally, the TAKCAL circuit can be used to trouble shoot and isolate errors in the aircraft tachometer system.

10) JETCAL Analyzer enables engine adjustment to proper relationship between engine temperature and engine RPM for maximum thrust and efficiency during engine run (Tabbing or Micing).

ALSO *functionally* checks aircraft Over-Heat Detectors and Wing Anti-Ice Systems (thermal switch and continuous wire) by using TEMPCAL Probes.. Rapid heat rise . . . 3 minutes to 800°F! Fast cycling time of thermal switches . . . 4 to 5 complete cycles per minute for bench checking in production.

Tests EGT System Accuracy to ±4°C at Test Temperature

(functionally, without running the engine)

Tests RPM Accuracy to 10 RPM in 10,000 RPM (±0.1%)

The JETCAL is in worldwide use . . . by the U. S. Navy and Air Force as well as by major aircraft and engine manufacturers. Write, wire or phone for complete information.

"STAR JUGGLER," a new interpretation by Simpson-Middleman, painters of the meanings of science. "We began to portray a sun as a stationary nucleus of a cosmic atomic system," recounts this imaginative team of artists, "but as the work progressed, there emerged a sense of movement, a suggestion of a sun swinging planets through space until they approached the stars in brilliance." Painting courtesy of John Heller Gallery, Inc.

You'll find an extraordinary future at Boeing

If you are impatient with ordinary achievement, you'll feel right at home at Boeing. For here you'll work with engineers and scientists whose habitual custom it is to push toward the future in giant steps. To cite just two examples: the Boeing 707 jet airliner, which at a stroke cuts commercial flight schedules in half, bringing the Pacific and Atlantic coasts within four hours of each other; and the Boeing B-52, which reduced the dimensions of the earth to a nonstop flight time of 45 hours, 19 minutes.

Today Boeing engineers invite you to join them on projects that open out onto the still more extraordinary vistas of the future: advanced supersonic aircraft and guided missiles, electronic and inertial guidance, chemical fuel propulsion.

There are openings at Boeing now for engineers of ALL categories, and for physicists and mathematicians. You'll find the future—your future—at Boeing, today!

Undersea Warning System Underway

Chain of Low Frequency Sonar Devices Will Detect Enemy Subs

By Erik Bergaust

The United States Navy is understood to be conducting a program for what may turn out to be the most sophisticated defense weapons concept ever attempted. We are building an underwater early warning system similar in scope to the famous radar detection systems stretching across northern Canada. But the USAW (Underwater Security Advance Warning) concept is based upon highly advanced underwater sonar devices linked together in long chains at the ocean floor up and down our coasts. The system is designed to detect enemy submarines that may sneak up toward our shores. This system—as part of an anti-submarine system—is believed to be our most potent answer to Russia's vast submarine fleet, many units of which are designed to carry the 700 miles range *COMET* FBM or IRBM missile. Employing the submarine launching concept the Reds would be capable of hitting targets along our coasts as well as inland from launching positions less than 100 miles out at sea.

The underwater early warning system is top secret. No details whatsoever can be released, although it is understood that certain companies, such as American Cable & Radio, have submitted proposals and might have been awarded contracts at this time.

Our undersea warfare people are working under tighter security wrap than any other branch of the services. Little has been said about their many different weapons systems and their research and development, but a high-ranking Navy official has confirmed to m/r that work is progressing on the underwater early warning system. Said one Navy captain, when asked how many subs we could detect if Russia sent 500 of them toward our coasts: "Today we probably could only detect 10 per cent of them."

The future system will be much like a chain of Texas towers deep down in the sea. Chains of sonar buoys, operating on a passive basis, i.e. *listening* for enemy submarine noise, would be linked together. At certain intervals computors will calibrate the sound wave information and transmit it to a central defense headquarters, much like the SAGE system.

Underwater experts agree the underwater warning system can be made effective, since advancement in the field of low-frequency sonar has been substantial, and since it his been proven that ships can be detected by passive sonar as far off as 100 miles, perhaps even farther.

During the war sonar was developed to the extent that a convoy could be heard with ease at 40 miles distance. A large ship could be detected 70 to 80 miles away, and an underwater explosion could be heard more than 100 miles away.

Many of the major electronics companies in this country are working on advanced sonar devices for torpedoes and other underwater warfare purposes. And the interest in this science is growing.

Navy's need for improved sonar devices—for underwater early warning along our coasts and for shipborne

Artist's conception of underwater early warning system. Enemy subs (A) will be detected up to 100 miles away by passive sonar buoys (B) that are linked together with computer system (C) and controlled from SAGE type headquarters (D). It will also measure sea conditions.

sonar—is expected to influence the electronics industry noticeably in the next few years. Some experts have even considered the possibility of hooking up an underwater early warning system to automatically controlled detonation devices and self-launching missiles. This may belong to the distant future. But the immediate application of sonar as a straight detection system is imminent and feasible as well.

Engineers For Sonar Industry

Recently Cal-Tronics Corporation of Los Angeles awarded a scholarship to a high-school student for his sonar electronic exhibit, displayed at the Annual Science Fair at the Los Angeles County Museum.

The winner was judged by Cal-Tronics executives including Malik Robinson, vice president; Ralph Koerner, manager of engineering; Stanley Boyle, development engineer, and Robert Feland, Jr., sales manager of the firm which specializes in testing equipment for guided missiles, radar and fire control.

The scholarship was awarded to stimulate recruitment of engineers for the growing electronics and sonar industries.

Unique Sub Detection System

A recent AP dispatch from Sweden disclosed that the Swedes have been considering the use of seals to hunt down submarines.

"Yes, we tried it," a naval spokesman told, "and you needn't get flip about it. The seals cooperated but we couldn't handle the fish."

Seals were put in training during World War II at a Swedish naval base, where submarines were sent down with bundles of fresh herring attached. The seals went for the herring joyfully.

There were two snags in the project, as the Swedes saw it, which had to be overcome to make it workable.

One was to supply the seals with "war heads." Since a seal's body is pretty streamlined and slippery, a top secret order went out to the Royal Institute of Animal Medicine to devise a suitable plastic operation to take care of this difficulty. This idea was discarded in favor of an "explosive harness" of special design.

The project foundered on the second snag. Despite intense training, the seals looked with perfect distain upon any submarine without the herring bait.

60-Knot Missile Subs Planned

A major technological breakthrough in underwater warfare is under way. It consists basically of the development of an engineering ability to break the "cavitation" barrier, that hydrodynamic phenomenon that now proves as troublesome to underwater missile and submarine designers as the sound barrier was to aerodynamicists a scant dozen years ago.

Vice Admiral Charles B. Momsen, USN (Ret.) in m/r's *personal report* (page 88, this issue) states categorically that 60-knot submarines are bound to come. It is not idle speculation.

He is a central figure in the work towards high-speed underwater capabilities. Now a consultant for such firms as Electric Boat Division of General Dynamics Corp., Coleman Engineering Corp., Fairchild Aircraft and Engine Corp., Raytheon Manufacturing Corp. and U.S. Rubber Co., Adm. Momsen probably knows more of the limitations and potentials of undersea warfare than anyone else alive.

A number of privately financed research and development projects, taken collectively, add up to just such a vehicle. The most important single contribution to the 60-knot (and up) submarine will be designed for the elimination of cavitation—a low-pressure turbulent flow condition where gas bubbles form between the fluid medium and the skin of the vehicle. Elimination of cavitation plus the development of highly-polished underwater surfaces might cut high-speed drag 70 per cent.

Details of specifically who is working on the 60-knot submarine and in what capacity are classified, both for military security and for proprietary reasons. But an official announcement that the Navy is building such a vessel may come this year.

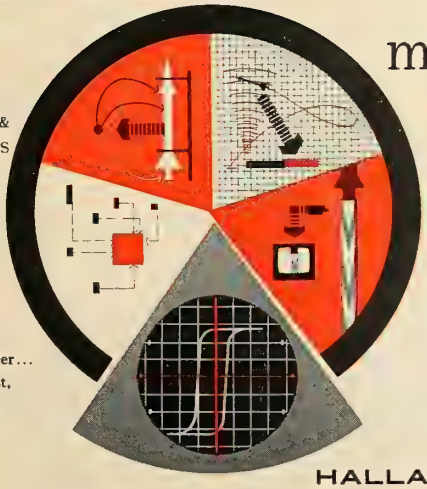
However, there are indications of what form it will take. First, it will probably be small and will be the most fully automated subsea craft ever launched. Its crew will probably consist of fewer than a dozen men. In that respect it will approach the airborne bomber in basic operational concept. Already, the revolutionary *Albacore* is "flown" with yoke, seat belts, etc. It performs a perfect needle-ball chandelle on rudder controls alone, obtaining the stability effect of dihedral by placing the center of buoyancy well above the center of gravity.

The 60-knot submarine will be nuclear propelled. Most importantly it will utilize a revolutionary system of hydrodynamic boundary layer control in order to maintain laminar flow throughout all speed ranges. It will have passive sonar gear with effective ranges reckoned in hundreds of miles.

It will be armed with reaction-propelled missiles with underwater speeds of 150-200 knots for anti-submarine (or surface ship) missions; with underwater-to-air anti-aircraft missiles; or, of course, the Fleet Ballistic Missile.

Increasingly, it will be necessary to design submarines for their special missions. Anti-submarine submarines will be like today's supersonic interceptor aircraft. Instead of carrying radar gear to detect and track their targets, they will be literally built around the finest sound detection gear possible. They will sit and listen in absolute silence for either the noise of an attacking submarine or a "bogey" report from USAW (Underwater Security Advanced Warning—Page 37, this issue). At this moment, the anti-sub submarine will either launch its missiles while at rest or streak off after its target, depending on the distance at which the detection was made.

The strategic missile launching submarine, cradling a *Polaris* nest will have an assault capacity on the entire land mass of Russia. Lockheed Aircraft Corp., though admitting that early FBM's will have only a 1,500 mile range, has strongly hinted that 2,000-mile missiles will follow shortly thereafter. This will be the big bomber of the submarine fleet, loaded to the gills with underwater navigational and computing gear and boasting at least two nuclear reactor engines for both speed and endurance. It will not be dissimilar in size and propulsion to the *USS Triton*, a twin reactor-powered radar picket submarine now abuilding at Electric Boat's Newport, R. I., yards.



Other submarine configurations will include anti-aircraft vessels that range the seas, ready to fire either beam rider or self-homing missiles from underwater at attacking aircraft or missiles; a privateer-like vessel possessing extremely high speeds, a variety of armament and with a mission to seek targets of opportunity of all sorts; personnel transporters; possibly aircraft carriers; and cargo vessels.

In the later regard, U.S., British and Swedish work on towed underwater bulk cargo barges is significant.

The breakthrough to 60 knots for submarines will be just a beginning. Aerojet-General Corp. is working on advanced underwater propulsion for missiles. This knowhow would be applicable to submarines.

Small as a portable radio...1/6th the size of a conventional vacuum tube unit of equal capacity...the Hallamore "Iron Autopilot," now in quantity production, amplifies guidance signals to provide positive impulses directing the missile along its flight path. Similar solid state devices are under constant study and development by Hallamore's Magnetics Group, providing the answers to difficult space and environmental problems encountered in the nation's missile program. Hallamore Electronics performs contracts for the United States armed forces and for prime contractors in the fields of missile ground support and instrumentation systems, audio and visual communications systems, electronic components, and magnetic products.

HALLAMORE ELECTRONICS COMPANY

a division of the ***SIEGLER CORPORATION***

Utica technician viewing a meltdown of Udimet 500—a new vacuum melted alloy in the high temperature field.

birth of a superalloy

Vacuum melted alloys, as developed by the Utica Metals Division of Kelsey-Hayes, provide extreme cleanliness; maximum chemical uniformity. They are superalloys, developed to withstand stresses and temperatures generated at supersonic speeds.

Utica, backed by the full resources and combined facilities of the Aviation Divisions of Kelsey-Hayes, is better equipped than ever before to serve the military, aviation and other industries.

VACUUM MELTING
provides these properties

- *High temperature corrosion resistance*
- *Increased ductility*
- *Extreme cleanliness*
- *Precise chemical control*
- *Longer stress-rupture life*
- *Increased tensile strength*
- *Better fatigue resistance*
- *Greater yield strength*
- *Greater impact resistance*
- *Greater creep properties*

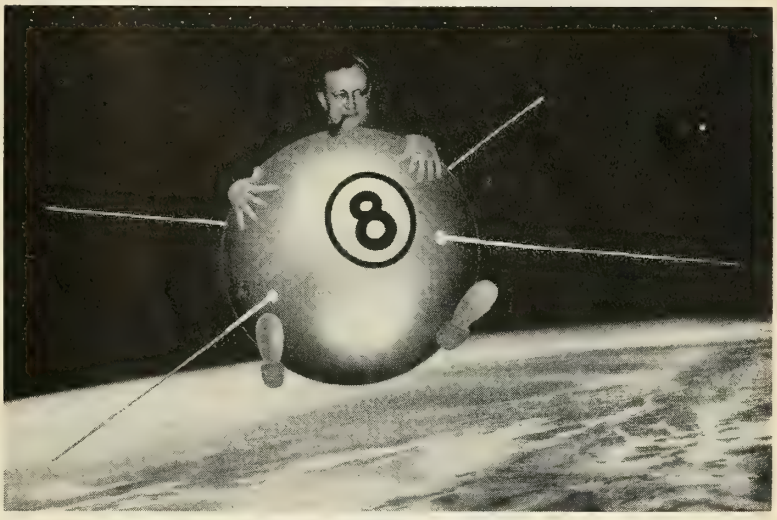
On-again, Off-again Missile Now On Schedule?

The now-it-will, now-it-won't missile, now, for the moment, will. The $39-million *Vanguard* now seems closer to being on schedule than it has in many months. In fact, with the recent successful firing of *Viking-14* with what is believed to be Grand Central Rocket Co.'s third stage *Vanguard* engine, the project may even be ahead of schedule.

The biggest question mark about when the U.S. would make its first "for keeps" effort to launch an artificial earth satellite has revolved recently around whether or not General Electric Co.'s first-stage engine would be successful. Early last month the press carried stories about how this phase of the project had been declared a failure, that Naval Research Laboratory might turn the Army Ballistic Missile Agency at Huntsville, Ala., for a first stage. The first three engines delivered by GE were, in fact, rejected as unsatisfactory. Now within a couple of weeks, this whole view has been reversed. The official word is that General Electric has solved its first-stage problems (reportedly, overheating) and that the engine is in the process of being accepted.



This series of events highlights the confusion surrounding Project *Vanguard*. Another contributing factor probably is the number of different agencies and groups having a hand in its direction. Also, as someone recently declared, "*Vanguard* is politically sensitive." This is particularly true where U.S. international prestige is concerned.

Other *Vanguard* developments include: completion of the purchase land for minitrack and visual tracking stations both here and abroad; beginning of construction and installation of gear at these locations; virtual completion in Washington, D.C., of the International Business Machines computer that will collect, colate and analyze reports from these and other stations.

A quick spot-check of the various major contractors in *Vanguard* propulsion indicates that the GE first stage is now all right; so, it is claimed, is Aerojet-General's second stage. Both of these are liquid rockets. Of the two third-stage competitors, Grand Central is reported to be completely out of any woods it might have been in—so confident in fact that some company officials have claimed that if the second stage liquid engine didn't pan out, they'd deliver a solid-propellant engine for that job in six months. Allegany Ballistics Laboratory, the other third-stage company, earlier was having trouble with burnouts in the engine's plastic casing, but it was confident of an early solution.

The Martin Co., *Vanguard* systems contractor, is now so confident of success of the project that it has recently hired a special man to handle all *Vanguard* publicity and enquiries. He is Dr. Donald Cox.

Meanwhile, with the last *Viking* having been fired, future launchings in the test series will probably be made exclusively with *Vanguard* components. Though all engines have been statistically tested many times, only one third stage has actually been launched. The tentative schedule now is to fire the GE first stage alone; GE first stage plus Aerojet second; then GE first, Aerojet second plus ABL third.

Aware of the telephoned, mailed and personal plaguing that Dr. John P. Hagen, Naval Research Laboratory Head of Project VANGUARD gets from quarrelsome cranks, well-meaning experts and the idly curious, an NRL photographer montaged Dr. Hagen behind the Vanguard eight-ball, a reasonable facsimile of which m/r reproduces here. Dr. Hagen's comment on seeing it was: "We can't have this kind of erroneous material leaking out of NRL. I have four feet—two of them for dragging when I'm asked to do something I don't want to do."

85TH CONGRESS
1ST SESSION

H. R. 2873

IN THE HOUSE OF REPRESENTATIVES

JANUARY 14, 1957

Mr. KARSTEN introduced the following bill; which was referred to the Committee on Foreign Affairs

A BILL

Officially designating the first earth satellite.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That Earth Satellite Number One be officially designated as the "Astranaut".

For the second straight year this bill, introduced by Rep. F. M. Karsten (D.-Mo.), is shelved in the House Foreign Affairs Committee. Karsten, wondering if the committee feels it doesn't have jurisdiction, has introduced a resolution to set up an Extraterrestrial Exploration Committee. Meanwhile, Astronant is no closer to being a name for VANGUARD'S pay load.

In the Aircraft Industry...

Solar is Synonymous with Stainless Steel

EXPERIENCE Solar has more experience in building airframe and engine components of stainless steels, titanium, and other advanced metals and high alloys than any other company in the world.

DESIGN Solar can greatly assist you in the design of components and assemblies to be built of high alloys—because of Solar's intimate knowledge of the problems and possibilities of these special metals.

DEVELOPMENT Solar is being asked to undertake more and more basic development projects in association with other companies—because of Solar's unique skills with advanced metals and their engineering.

MANUFACTURE Two large plants offer strategic dispersion with integrated, experienced management. Solar's production record is unmatched for quality, service, dependability, and prompt delivery.

FOR MORE INFORMATION ABOUT SOLAR'S CAPABILITIES, WRITE DEPT. D-21, SOLAR AIRCRAFT CO., SAN DIEGO 12, CALIFORNIA.

Underground Missile Plant to be Built Near Redstone

HUNTSVILLE, Ala.—The White House-State Department decision to supply the members of the North Atlantic Treaty Organization in Europe with missiles for mutual defense has resulted in an acceleration of activity at Redstone Arsenal, Army Ballistic Missile Agency and the Ordnance Guided Missile School. Employment at the three agencies has risen from 12,000 in December to 14,000 as of now.

And in the wake of the NATO decision several of the companies which have begun operations here in the past few years to work with the missile and rocket development teams at Redstone and ABMA, have been increasing their local personnel and planning for an expansion of activity that seems to be leading them more and more toward the manufacture of larger quantities of components and parts and even complete missiles. These include Chrysler, Thiokol, Aerojet-General and U.S. Industrial Chemicals division of National Distillers.

There has also been increased activity on the part of American Machine & Foundry which holds the rights to excavate nearby Green Mountain for what is commonly supposed to be the first U.S. underground factory for the manufacture of missiles and rockets, coupled with a sort of subterranean "junior Pentagon" where elaborate headquarters would be installed to direct the defense of the southern U.S. against enemy attack.

Several citizens of Huntsville have obtained permission from the State Docks Commission to purchase from the Tennessee Valley Authority some 200 acres of land on the Tennessee River for the purpose of building new docks that would serve the AMF underground factory. The money has been raised for the purchase and final consummation awaits only the completion of legal formalities.

Simultaneously, a new company, known as Chemstone would construct a limestone processing plant to crush the rock excavated from Green Mountain, converted into cement and other products and ship it out via the new docks. Involved in all this activity is a payroll of some 5,200 persons—or at least a 10% boost in the population of Huntsville, which has grown from 16,000 persons in 1950 to 52,000 today.

Another reassuring development has come in the refusal of the team led by Dr. Vernher von Braun to forsake their duties at Redstone and ABMA for many luring offers made by private industry located elsewhere. Despite all the hullabaloo since the Wilson decision of last November and the known presence here of "talent scouts" from a dozen or more large firms deeply interested in missiles and rockets, only one minor defection has occurred from the 125-member team, and this was a very subordinate man who had joined the team late, having come over from Germany only two years ago. So far, the original von Braun coterie of former German missile & rocket scientists remains intact, although von Braun himself and some of his associates have reportedly received upwards of 40 offers from as many outside firms.

Meantime, three well-known firms interested in missiles and rockets have inspected the 800,000 square feet of modern plant space available for purchase or lease following the demise of a cotton mill. All of these are firms which have been manufacturing parts, components and complete missiles.

The quantities of weapons that will be required by the 15 member nations of NATO will certainly give the Army new arguments for expanding its own development and research activities and perhaps also to build up at last its own industrial complex for the production of missiles and rockets and to create the private industry team, the lack of which has provided critics of the Army with potent arguments.

German Rocket Society Learns by Doing

The Deutsche Arbeitsgemeinschaft für Raketentechnik (DAR) of Bremen, although only two years old, is attracting wide interest in their activities. Headed by an enthusiastic engineer, A. F. Staats, the Society is investigating a number of applications for rockets. In addition to the "oil-spray" rockets (m/r April '57, pg. 88) liquid propellant and hybrid motors are being designed, built and tested. Sounding rockets built so far have reached only modest heights but the fact that all components, including gyro stabilization and recovery gear, have been produced by an amateur group is remarkable. Three-staged sounding rockets are being built to be launched during the IGY. Students joining the DAR are intensively drilled in basic rocket technology and principles of astronautics. Practical experience is gained as helpers and workers in constructing and launching.

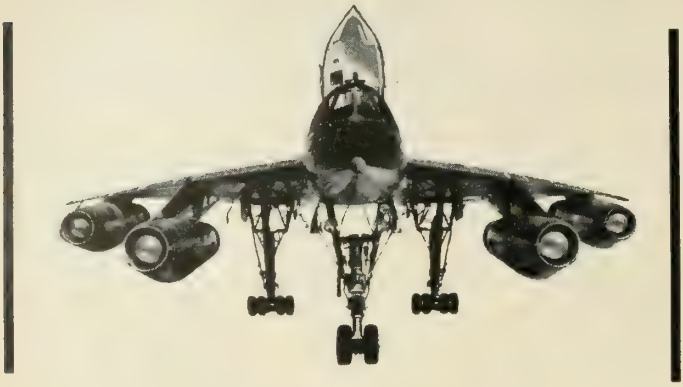
German "do-it-yourself" experiment.

Measuring Devices Readied for Satellites

Two new measuring devices are being readied for future use as part of the astrionics gear to be carried in satellites.

Varian Associates, m/r learned, has just received the go-ahead to build a light-weight version of its proton precession magnetometer for measuring values of magnetic field encountered by a satellite during its orbit.

The magnetometer operates using the principle of nuclear magnetic resonance simultaneously discovered by Dr. Felix Bloch at Stanford University and Dr. Edward M. Purcell at Harvard University in 1946.



The two scientists were jointly awarded the 1952 Nobel Prize in Physics for their work which was done independently using different methods.

Varian's estimate of the satellite magnetometer's weight is about 4-4½ pounds with an absolute minimum of 3½ pounds. However, in a report by Varian to the Naval Research Laboratory it was noted that the device would not be ideal.

An ideal device would be able to record, with extremely high signal-to-noise ratio, all values of magnetic field during one trip around the earth.

The information would be recorded and then "dumped" upon interrogation from the ground when the satellite was over a recording station.

However, storage is a big problem at this time, and according to the report, storage of full magnetic field

Honeywell's Variable Inlet Diffuser
Controls Keep the "Hustler" Hustling

ENGINEERS
SCIENTISTS

WORK ON ADVANCED PROJECTS LIKE THIS

As mach numbers advance, even fractional errors in inlet-air diffuser positioning reduce thrust tremendously.

Yet a fixed diffuser designed for optimum pressure at a given high mach number may be so inefficient at a lower mach number as to render it impossible for aircraft to reach design speed.

In the U.S.A.F.'s first supersonic bomber, Convair's B-58 Hustler, this problem was solved by Honeywell's variable inlet-air diffuser systems—the most accurate known. They are automatically controlled to the proper parameters to achieve maximum pressure recovery and mass air flow matched to engine requirements.

The Challenges to Come!

Variable inlet diffuser systems are just one of 114 research and development projects in which Honeywell Aero is engaged. These projects are in the basic areas of:

INERTIAL GUIDANCE • FLIGHT CONTROL SYSTEMS • LIQUID MEASUREMENT SYSTEMS • VERTICAL, RATE AND INTEGRATING GYROS • DIGITAL AND ANALOG COMPUTERS • JET ENGINE CONTROLS • AIR DATA COMPUTERS • BOMBING COMPUTERS TRANSISTOR AMPLIFIERS • INSTRUMENTATION

Each of these projects offers exceptional career opportunities for capable engineers and scientists.

And Honeywell's rapid growth assures you of early advancement. Engineering personnel at Honeywell Aero has tripled in the last 5 years, is still growing faster than the avionics industry average. Supervisory positions open quickly, are filled from within. The first-rate salary you start with at Honeywell is *just the start.*

Write today!

For more information concerning these opportunities, send your inquiry or résumé to: Bruce D. Wood, Technical Director, Dept. TA19C, Honeywell Aero, 1433 Stinson Boulevard, Minneapolis 13, Minn.

Honeywell
Aeronautical Division

strength may not be feasible in the first tests. Instead, spot checks may have to be made.

A new development in high-capacity light-weight recording devices holds out hope for inclusion of such a system among early experiments.

The State University of Iowa has built a tape recording system that weighs 6½ ounces and has a 48 channel capacity. Bandwidth of the system is 15 kilocycles. Power supply for the recorder will last four weeks.

Another recorder suitable for satellite use has also been built by the Signal Corps. One of the primary scientific tests in which the Signal Corps is interested is measurement of the earths' albedo or cloud coverage.

New Transistors Developed by GE

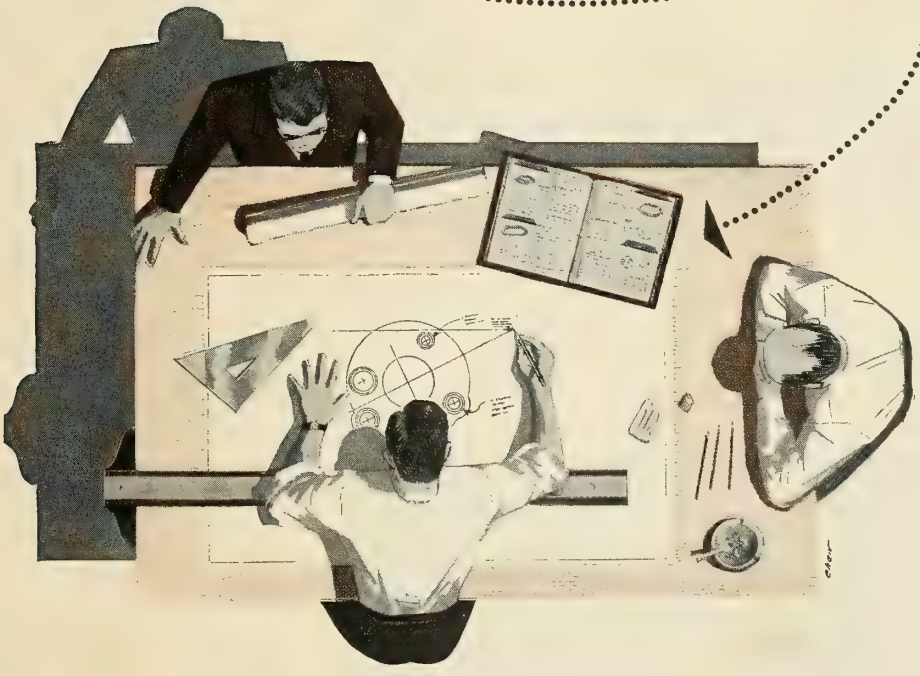
Development and production of three new high frequency transistors by the General Electric Co. is expected to extend the applications for these devices in equipment now limited to vacuum tubes.

The three new units are germanium tetrodes and one is designed for amplification at 120 megacycles, according to GE.

Characteristics of the new 3N29, 3N30, and 3N31 types call for a minimum gain of 10 db at 30, 120 and 15 megacycles respectively. Dissipation is 50 milliwatts at 25 degrees C.

For local oscillator use frequencies are: 3N29-50-60 mc, 3N30-200 mc, 3N31-30-40 mc.

New Publication On Electron Tubes



A new quarterly bulletin on electron tubes is being published to provide information to government agencies and contractors on research and development programs being sponsored by the military departments.

Known as *A.G.E.T. New Bulletin,* its publication began in January, 1957 to further objectives of the Advisory Group on Electron Tubes established by the Asst. Secretary of Defense (R&D) to achieve an integrated R&D program for electron tubes and semiconductor devices.

Information of a general nature which surveys state of development and new developments just started will be included in the *bulletin.*

Publication is by A.G.E.T. at 346 Broadway, New York 13, N.Y.

. . . good sealing begins here, too!

When the problem of sealing is a part of *design thinking* the whole design is bound to be better. This is especially true of *no-leakage* sealing. When your designs require sealing . . . from −400° to +1000° . . . why not call in one of our field men. One of the "O-seal" family°, may be the answer to save you time, money and effort.

Circle No. 11 on Subscriber Service Card.

Douglas Aircraft has made a proposal to the Air Force to build some new, giant-size transports capable of hauling an Atlas ICBM to any location in the world. Although WDD's General Ben Schriever is understood to be very much interested in the concept—appreciating the necessity for mobility in a future war—Air Force does not seem to have the funds for the king-size planes right now. No details on performance were given for the proposed aircraft, although some payload specifications have been discussed in the open. The larger version of the Douglas transports would be capable of hauling a complete Atlas and launching crew. Top picture shows C-133 now being built. C-132 is out for the time being. Both planes are turbo-prop powered.

Trajectory Analysis
for ICBM and IRBM

Flight Mechanics

Ballistics

Orbital Mechanics

Flight mechanics, ballistics, and orbital mechanics are among the areas in which there are current openings at Ramo-Wooldridge, where engineers and scientists are providing over-all systems engineering and technical direction for the Air Force Ballistic Missile programs. These positions are centered about the calculation and evaluation of missile trajectories, utilizing the services of a digital computation group. Trajectory determinations, in turn, affect missile systems design and flight test.

Education and experience should be in one or more of the following or related fields: aeronautical engineering...aerodynamics...flight mechanics ...performance analysis...rocket propulsion... applied physics...applied mathematics.

Inquiries regarding these opportunities should be addressed to: Mr. W. J. Coster

The Ramo-Wooldridge Corporation
5730 ARBOR VITAE STREET • LOS ANGELES 45, CALIFORNIA

GE Gets $83-Million *Atlas* ICBM Contract

General Electric Co. has announced receipt of a $83-million Air Force contract for "work in connection with guidance of the *Atlas* ICBM."

Role of GE's Heavy Military Electronic Equipment Department which will do the work was announced last year, but the size of the contract was not disclosed.

Also revealed was formation of a new Missile Guidance section of the HMEE department. R. L. Shetler will head the new section.

Shetler noted, "With this job behind us, there will remain no significant obstacles to the practical guidance and navigation of other space vehicles."

GE will divide the work between its Syracuse, N.Y. and Utica, N.Y. facilities. Additional space in Utica has been obtained, and 400 employees have been transferred there from the other Utica location.

Mich. U. to Hold Management Courses

University of Michigan will present a group of courses in management science and computer technology from August 19 to 30.

The short courses will feature a scientific approach to management decisions.

Attention will be focused on a comprehensive approach to planning, organization and control. These will include use of the digital computer, probability, statistical inference, methods of programming business operations and consideration of human capabilities and limitations.

Enrollment is limited to fifty students holding the equivalent of a four-year college course in business, engineering or science.

Transistor Output 59 Million by 1958

Latest forecast on the future transistor market has been released in a market survey made by the Stanford Research Institute for the Philco Corp.

The Stanford report included information supplied by 80 companies who cooperated in the survey.

Forecast was a production of 59 million germanium and silicon transistors in 1958, and 125 million units by 1959.

"PEDIGREE ... 2 TO 3"

Today, Narmco's structural adhesives, laminating materials, coatings, putties and resins have greater strength at higher temperatures ... allow quicker cures with less preparation ... are less expensive ... more readily available ... and have longer shelf life than ever before.

This has been no accident. It happened because a *key* ratio, possibly unique in the industry, was painstakingly created in the Costa Mesa, California, plants of Narmco Resins and Coatings Co.

The key ratio is 2 to 3!

This is what it means to you. In today's scramble for lighter, stronger, more heat resistant materials, organizations ... to serve you best ... must have a potent, steadily growing research capability. At Narmco two researchers ... chemists, physicists, engineers ... are employed for every three production workers!

To you who use Narmco products in the production of aircraft and missile parts and assemblies, this means steadily improving materials ... of a quality you can depend upon ... at lower cost ... and delivered when needed to meet tight production schedules!

It also means new materials that *do jobs every day that metals alone can't do* ... materials essential to the successful design and fabrication of tomorrow's aircraft and missiles!

NARMCO

PIONEERING THROUGH RESEARCH

Narmco technical field representatives throughout the United States and Canada can assist in solving your structural design problems quickly, efficiently and economically. For immediate assistance, write, wire or phone ...

NARMCO RESINS & COATINGS CO., Dept. 17 600 Victoria Street, Costa Mesa, California

MIT Discloses Work on Inertial Guidance

After 18 years of security classified work in the development of gyroscopic instruments, the Instrumentation Laboratory of MIT opened the door and disclosed some details of their work. At a press conference recently, Dr. C. S. Draper, Director of the Laboratory and head of MIT's Department of Aero Engineering, lectured reporters on basic elements of inertial guidance and showed examples of their Hermetic Integrating Gyro (HIG).

The Model HIG-3 contains a gyro wheel which spins at about 12,000 rpm within a cylinder which floats in a heavy molasses-like fluid within another cylinder. Overall size resembles a tomato can. The floating gyro container pivots on sapphire bearings which are virtually frictionless. It is the concept of the "floated gyro" that is considered a major breakthrough in gyro technology. A miniaturized Model 10-I-G weighs about 3 oz. Power requirements are only 3/8 watt permitting transistorized circuits. It is understood that in May the USAF will make drawings of this circuit available to manufacturers.
